CASE 1.—The first part of the following account is derived from notes which were carefully taken at the moment of observation and which were meant for earlier publication, an intention, however, which was postponed from the desire to wait for further developments which might throw fresh light on some puzzling features of the case. The patient, an unmarried woman, aged 39 years, first came to my consulting room on April 21st, 1893. The first glance at her swollen lips and her first efforts at speech seemed immediately to stamp the case as one of myxœdema and this opinion was strengthened by the fact that she was the sister of a cretin whose case I reported in 1884[2] and who died in an extremely swollen condition. A look into her mouth showed that the tongue and especially the soft palate and uvula were much swollen and the threatening aspect of the case induced me to send her straight home. Visiting her there an hour afterwards I ascertained that she had had a similar but much milder attack a week previously which had passed off in 24 hours. Both attacks commenced very suddenly and in neither was there any preceding rigor. The day before the present seizure she had been exposed to cold in a boat, but there had been no such exposure on the previous occasion. On the morning of this second attack menstruation had commenced although it was not due for a week longer (this being a novel occurrence with her), and four hours later she suddenly felt giddy and was obliged to lay hold of something for support, but this passed off in half-an-hour. Two hours later she suddenly felt her lips "blister," as she expressed it, when she touched them with her tongue and they swelled up to twice their usual size in five or 10 minutes, her throat became dry, and swallowing was difficult, and in half-an-hour there was a burning pain in both the tongue and the throat, most severe at the tip of the former. She was now in great distress and alarm, feeling as if she would soon "close up" altogether. I now found that the enlarged uvula had become very red and vascular in the brief interval which had elapsed since my previous examination. The lips were enormously swollen, the upper being traversed by a transverse furrow dividing it into two large ridges, while the lower, still more thickened, was much everted and covered with a copious tenacious mucus manifestly oozing from the inflamed surfaces. The swelling was almost completely submucous and not cutaneous, while the gums, the buccal mucous membrane, and the hard palate were practically unaffected. The anterior half of the tongue was of twice the usual thickness and very moist, this thickening being most marked on the lower surface, which presented the appearance of two considerable longitudinal ridges with a central furrow, an exaggeration of the normal condition. The papillæ were very prominent on the upper surface, giving rise to a strawberry appearance as in scarlet fever. The posterior half of the tongue seemed almost normal, a well-defined transverse line demarcating the two halves. On the soft palate or at its junction with the hard there were two distinct oval, red, vascular patches on each side of the middle line, elongated from before backwards and a little larger than horse-beans. There was a clear space between these and the enlarged and vascular uvula. The pillars of the fauces were slightly reddened but the tonsils, pharynx, and the parts beyond were quite unaffected. The patient said that the tongue felt as if a hot cinder were lying on it. She was hawking and spitting incessantly a large quantity of viscid saliva. There was no difficulty in breathing. Speech was impaired and the sense of taste was nearly lost, while she could bear nothing in the mouth but cold water and milk which relieved the burning sensation. The lower half of the face appeared to be swollen and there was some fulness below the chin, but the upper half of the face and the eyelids were unaffected. The right submaxillary gland was enlarged and somewhat tender but not the left; there was no swelling of the parotids. There was no tenderness over the thyroid and I was doubtful if the gland could be felt at all. The pulse was 60 and feeble, as also were the cardiac sounds. The temperature, which was taken with scrupulous care, was 99° F. in the mouth and 98·6° in the axilla. There was very considerable thirst. An aperient with the use of iced water and milk was ordered.

[2] THE LANCET, August 23rd, 1884, p. 314, where an illustration is given

It was chiefly during subsequent visits that the previous history of the patient was elicited, but the sequel will be better understood if it be inserted here. She first of all stated that she had always been in good health until the present attacks, so that had I been satisfied with this and been content to regard the myxœdematous aspect as due only to the present acute swelling, as no doubt it was to a large extent, I would have failed to apprehend the real nature of the case. On inquiry it turned out that she had had a dry and scaly state of the skin of the face, forearms, and hands for five or six years, for which she had used glycerine every night, while an eruption of reddish watery spots frequently broke out about her wrists. At the same time she had not felt so strong as formerly; her appetite had failed; she had become very susceptible to cold, often feeling shivery; she was easily fatigued and had become slow in walking, but without unsteadiness of gait. Speech was unimpaired, but she had a bad taste in the mouth and was troubled with a copious tenacious saliva which even trickled from her mouth and moistened the pillow at night. Her complexion had become yellowish of late. There were two well-marked pink areas on the cheeks, and when I called her attention to these she said that they had always existed but that they grew excessively bright of late if she was near a fire. She had grown stouter within the last few years with a tendency to a "hanging" chin, but the lips and eyelids had never been swollen although her sister had often remarked a blueness of the lower lids. In September, 1892, she first experienced a "blistering" of the lips as felt with the tongue with a peculiar sensation of smoothness about the latter. This would last a few hours and return in a few days or weeks. Her hair and nails were normal with only slight brittleness of the latter. The memory was slightly impaired. The inquiry was further directed to the various other symptoms and appearances of myxœdema as enumerated in the exhaustive report of the Clinical Society of London and with negative results.

To return to the present acute affection: the same evening the throat and tongue were worse and the patient was protruding the latter frequently to cool it. A dose of thyroid extract corresponding to one-twelfth of a lobe of the sheep's gland was administered. (This was prepared by myself the same day. The acute symptoms were, as far as my knowledge went, unprecedented in myxœdema, but I had no suspicion of any external irritant cause and treated the general cachexia. Apparently marked improvement always followed the use of the remedy.) On April 22nd she had improved; the swelling had diminished and the burning was relieved; the patient had slept for an hour in the morning. There was now some prominence of the mucous membrane of the nose on each side of the septum. The lips were thinner and had little moisture on them and had now a somewhat withered, leathery appearance. The tongue was normal in size, but presenting an oval patch of exfoliation near the point, longest transversely. The soft palate and uvula were now uniformly red. The temperature in the axilla was 98·6°. A dose of extract equal to one-sixth of a lobe was given. On the 23rd the patient was much improved; she had slept well the previous night. The soft palate was as red as ever; the exfoliated patch on the tongue had disappeared. The temperature in the axilla was 98·6°. No extract was given. On the 24th the uvula was still a little swollen; two red oval patches were now seen on the hard palate on each lateral half; the lower eyelids were now somewhat puffy. The temperature in the axilla was 98·5°. No extract was given. On the 25th there was sudden recurrence of irritative symptoms in new situations. The patient stated that the burning in the throat and tongue had returned with considerable severity the previous afternoon for several hours, but did not lead to salivation. On the morning of the 25th at 1 A.M. she was roused suddenly out of sleep by a burning sensation in the face and hands which felt as if they were being "roasted"; this passed off rather suddenly about 3 A.M. At the first glance on my arrival the face was seen to be much broader, with a fulness under the eyes. The pink areas on the cheeks, especially the right, were the seat of a vesicular eruption which was even more marked below the patches where some of the vesicles, seated on a reddened base, were oozing out serum and there was a similar angry rash on the chin. The burning had now given place to an itchy sensation and there was a numb feeling about the hands and in the thumbs more especially. The fingers were swollen and on the back, next the nails (and this was more marked on the thumbs), the skin was quite red for half an inch or so. Irritation had quite gone from the mouth, where all the parts were nearly normal; speech had improved and taste in the mouth was returning. The temperature in the axilla was 98·5°. Ten minims of Brady and Martin's extract of thyroid were now given.—On the 26th there was an astonishing change; every trace of eczema or irritation had gone; the face only was a little swollen; the most pronounced remaining sign of myxœdema was the tawny yellow colour. The patient now felt so well and lively that she "could do anything." The temperature in the axilla was 99°. No extract was given. On the 27th the patient was very well; the temperature in the axilla was 98·4°. Five minims of extract were given. On the 28th the temperature in the axilla was 98·8°; the patient was very well, but some redness of the gums was present, especially of the lower. No extract was given. On the 29th the temperature in the axilla was 98·4°; she said that she had not felt so well for some years; she had got thinner, her thumbs being thrown into wrinkles The lips, tongue, and uvula were normal Menstruation ran its usual course in the case and it recalled to my recollection that of a woman who had attended the dispensary of the Glasgow Western Infirmary for some uterine affection and who at one of her visits stated that at her previous menstrual period (as also during the present one which was in actual progress) she had had a sore tongue and throat, and the following note was taken at the time "Point of tongue red and almost denuded of epithelium, on throat an eruption like scarlet fever" There was nothing about this patient to raise the slightest suspicion of myxœdema, but at that time I did not dream of looking for any connexion with the latter

The urine in the above case was examined on April 28th after menstruation had ceased and it showed the following characters, it was pale, feebly acid, and of specific gravity 1017, there were no albumin no sugar, and very little mucin Much of the saliva if the excretion from the mouth can be so called, had, contrary to orders, been thrown away, but a few ounces were obtained which presented the following characteristics it was very turbid, depositing shreddy coagula, but without ever becoming clear above, its specific gravity was from 1010 to 1011, neutral, or faintly alkaline (!), it was very viscid, becoming *ropy* with alkali, there was little frothing power The filtrate contained 1 224 per cent of albumin, some globulin while mucin could be detected up to dilution with 50 volumes of water Dr R M. Buchanan, pathologist to the Glasgow Western Infirmary, examined it for uric acid by Sir A Garrod's thread test, but found none He found that the deposit contained, besides blood colouring matter and débris, numerous nucleated epithelial cells, many of them oval and often coalesced into a mass It is unnecessary to point out the analogy, or rather *identity, of the acute swelling in this case with what has* been described as angio-neurotic œdema occurring especially in neurotic females of a gouty diathesis and in other conditions

Subsequent history —The patient continued very well for some time, but the myxœdematous physiognomy again developed, with now subnormal temperature, as tested on several occasions, so that she was put on *thyroid treatment* This improved her condition in many respects, but ever and anon, and apparently in spite of the treatment, she suffered from severe dermatitis of the face and hands, although the mouth was never afterwards affected as before At one time her face was so bad that I sent her to a skin dispensary, where an eminent specialist pronounced the case to be erysipelas and applied something which made her worse instead of better At length she mentioned her case to a gardener from whom she had just procured some specimens of primula obconica who at once told her that the plant was the cause of her trouble and that he knew of similar cases, one especially of a titled lady who had suffered severely from the effects It turned out that my patient had all along been cultivating and frequently handling this plant and she stated that she had occasionally chewed the flowers and swallowed the juice but could not say whether she had done so shortly before either of the acute attacks here recorded The noxious plant being now discarded there was no further return of the mischief except on one occasion when from curiosity she held a leaf in contact with her lips for a short time, soon after which they, together with the point of the tongue, swelled up for some hours The important facts remain to be added that she had handled the plant for one or two years before the first blistering of the lips was experienced whilst the rest of the family had been unaffected by it although a sister was as much given to chewing the flowers as the patient herself,

Numerous cases in which this irritant has produced similar, but rarely if ever so severe, effects as those observed in this case have been recorded of late in both medical and lay journals and from these several sources the following facts stand out prominently (1) that the effects are described as erysipelas, urticaria, but more especially as eczema of the face and hands, sometimes attended with much swelling, (2) that some constitutions are specially susceptible while others enjoy immunity, and (3) that apparently the majority of sufferers have been females, although on the latter point the evidence is not decisive From all the facts it seems reasonable to conclude that the above case was the product of two factors—an external irritant and an internal predisposing cause The latter seems to me to be the more important and we naturally look for it in the existence of morbid products in the parts affected The conflagration which broke out there appears, speaking generally, to have consisted in an oxidation and elimination of those waste materials and hence was essentially curative. Mere contact with the irritant cause does not seem satisfactorily to account either for the parts attacked or the effects produced, and we may ask, were the latter due to a direct action on the tissues concerned or to the stimulation of a partially incompetent thyroid gland? At all events, we find in this case the general physiognomy of myxœdema developed in a few hours, or rather minutes, and the uvula presenting (when first seen and before it became vascular) the same appearance and causing the same snuffling speech as in chronic myxœdema The case seems to suggest that some preparation of the primula or other similar plant might be of value for diagnostic or even therapeutic purposes Indeed, it has been already used with the latter object in view, for Dr Riehl of the University of Vienna is said to have found that the irritant principle resides in the tiny hairs of the leaf and stalk and to have prepared from them an extract with which he claims to have cured some obstinate cases of skin disease[3] The hairs had been previously ascertained to be glandular by Dr Wilson of St Andrews[4]

In January of the present year this patient had a febrile attack which lasted a week, during which the temperature rose as high as 99 6° On recovering she felt in better health than before and it seemed probable that she had not been taking a sufficient quantity of thyroid extract And now a fact came out which had not been brought to light by all the previous inquiry At the age of 28 years (corresponding to the time when the dry state of the skin commenced) she experienced a pain in the right side of the neck shortly after an occasion of great grief and this was accompanied by a choking sensation which seemed closely connected with it This lasted about a year and long afterwards she was conscious of discomfort in the same situation on swallowing anything cold On being asked to point out the spot she placed the point of her finger directly over the right lobe of the thyroid and careful manipulation now seemed to indicate that here the gland was more or less *atrophied, while there was a comparative fulness on the left* side, although I must confess that I cannot speak very positively on this matter

CASE 2 —A very brief notice of this must suffice An unmarried woman aged 36 years, had consulted me at intervals for two years or more complaining of symptoms of failing health, which I treated by tonics &c without benefit It was not until one day in April 1898 that she presented herself before me with a physiognomy so unmistakeably indicative of myxœdema that I recognised the fundamental cause of her ailments Besides some swelling there were now present subnormal temperature impaired memory, difficulty in deglutition, the saliva sometimes even trickling from the mouth and scanty brown and watery menstrual fluid The thyroid treatment was promptly followed by the usual success, even the menstrual function being restored to its original state of vigour, this and its previous failure being points of exceptional interest It was now obvious that this case might have been diagnosed at an earlier date, but at the same time *the present cases show that the effects of* thyroidal inadequacy or irregularity may be more multifarious than has hitherto been supposed It was in December, 1898, that an acute attack from which the patient suffered resembling urticaria œdematosa led me to reflect on her still earlier history In this seizure, which came on two hours after a hot bath her face suddenly flushed up and the eyelids swelled, and this flush shifted rapidly to other parts, as the arms the thighs and legs, and the trunk where it appeared in patches which, however, were never pale in the centre It was accompanied with a distressing scorching and tingling sensation It not only shifted to and fro, but sometimes disappeared from the skin altogether, and at these times the patient felt a burning sensation in the epigastrium and abdomen generally, which again was instantly relieved on the reappearance of the eruption There was also said to be some sore throat I did not see the patient till the fourth day when the worst symptoms had subsided, but the appearances I may note were as follows there was no rise of temperature, the *skin of the face was dry and shrivelled*, with elastic œdema of the eyelids which were waxy looking the eruption on the chest was indistinguishable from scarlet fever. Slight if any desquamation followed. Some days afterwards I found the temperature subnormal, and learning from the patient that she had been previously chilly I told her that she was probably not following out the thyroid treatment with sufficient regularity. Now the patient had been under my own care with severe facial erysipelas four years previously and twice within the same year and once again two years later had had attacks similar to that already mentioned but milder in character. She dated the commencement of her progressive illness from a period about three or four months antecedent to the attack of erysipelas. After exposure to cold she began to suffer from cough, pain in swallowing, and a feeling of suffocation, starting from the midriff and extending over the front of the chest, which rendered inspiration oppressive and difficult. She afterwards complained that I paid little attention to these symptoms; and, indeed, finding them persist without any adequate cause being revealed by auscultation I had come to regard them as hysterical, for I knew that she had a certain alloy of this temperament. On inquiry at a later period it was found that the pain in deglutition was seated over the thyroid in front and that the same spot had been painful on pressure. It should be observed that the patient always spoke of this part as the "throat" which is often used to denote the whole front of the neck. The difficult deglutition, which ensued later was referable to two localities, one being the fauces, where it was due to sluggish muscular action, and the second the site of the thyroid. A later symptom worthy of note was a stinging pain in the left iliac region which radiated backwards towards the sacrum and down the inner aspect of the thigh as far as the foot and was apparently of ovarian origin. This came on several months before myxœdema was diagnosed and had become so severe that it was the principal cause of bringing her to me at that time. She also suffered from tremors, vertiginous attacks at night, and felt as if she "were going out of her mind" and becoming incompetent for the duties of life. It is obvious that all these symptoms might be referred to hysteria; if so, the important conclusion seems to follow that hysteria itself in this case was dependent on thyroidal irritation, for all the patient's troubles vanished under thyroid treatment and are apparently only kept at bay by it, for they threaten at once to return whenever it is left off for a short time.

---

[3] The English Mechanic and Gardeners' Chronicle, April and May, 1895.

[4] The

I now incline to the view that thyroidal inadequacy was the predisposing and all-important cause both of the erysipelas and urticarial attacks, for which latter no error in diet or drug or other source of irritation could be discovered. The influence of heredity and constitutional states in these affections is worthy of notice in this connexion and it soon appeared that the former had its share in this case also so far as the myxœdema was *observed*. No sooner had the patient experienced the benefit of the thyroid treatment than she expressed her conviction that a married sister living in Ardrossan must be the subject of the same disease. On visiting the latter I found it was even so; she was already, at the age of 50 years, in an advanced stage, with great impairment of the mental faculties, besides being nearly deaf and blind. I left her for thyroid treatment under the care of Dr. J. McDonald who lately reported that the swelling had disappeared except over the abdomen and that there was improvement in hearing, physical capacity, and mental powers. I cannot detect any trace of the thyroid in Case 2 and she cannot do without a thyroid tabloid for more than a few days, while Case 1 can sometimes dispense with the remedy for a month. Both are positive in asserting that there never was any swelling in the region of the gland. Nevertheless, do not these cases lend some countenance to the supposition that besides sudden and violent perturbations of thyroidal function there may be such an affection as an acute thyroiditis which may sometimes be the starting-point of atrophy and fibrosis?

Glasgow.

Montgomeryshire Infirmary.—The annual general meeting of governors was held at Newtown on Feb. 23rd, Mr. R. E. Jones presiding. The board of management reported that the adverse balance had increased during the year from £96 to £214 in consequence of the additional accommodation provided for special cases. The medical staff was re-elected and on the motion of Mr. Harold Palmer, seconded by Mr. J. C. Gittins, Dr. Edward Cureton (Shrewsbury) was appointed an honorary consulting physician of the institution.

INJURY TO THE VAGINA, THE RECTUM, AND THE PELVIS;

SUBSEQUENT NECROSIS OF THE PUBES AND PREVESICAL ABSCESS; OPERATION; RECOVERY.

By H. BETHAM ROBINSON, M.S. Lond., F.R.C.S. Eng.,
ASSISTANT SURGEON TO, AND SURGEON FOR DISEASES OF THE THROAT AT, ST. THOMAS'S HOSPITAL; ASSISTANT SURGEON TO THE EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL.

The following case merits attention from the unusual sequel of a crushing injury to the pelvis and soft parts.

A girl, aged 10 years, was admitted into St. Thomas's Hospital under my care on August 10th, 1895. When crossing the road on that day she was knocked down by an omnibus, the front wheel passing over her lower abdomen. On admission she complained of intense pain above the pelvis and there was considerable bleeding from the vagina. On examination under ether it was discovered on separating the labia that the mucous membrane of the vagina had retracted upwards, being completely torn away round its orifice but behind the hymen below: the wound here was complicated by a rent in the recto-vaginal septum. Owing to the retraction of the vagina there was distortion of the urethra but apparently there was no wound in it. There was no evidence of any fracture of the pelvis in the way of abnormal mobility and there was no blood in the urine when drawn off with a catheter.

The retracted vagina was brought down and its margins were stitched with silk, as far as possible in their original site; thus the orifice of the urethra was replaced in its natural position. At the lower part where the rectum was rent this was sewn up but the wound was only small.

The notes of the case for August 12th state that since the accident the patient had had retention of urine, and that the urine had to be drawn off by catheter, some difficulty presenting, however, owing to the swelling of the parts. The wound on that date looked very sloughy, but there was no tension. The temperature varied between 100° and 101·8° F. The patient was put into a boric lotion bath. On the 14th the temperature still ranged from 100° to 101·8°. The urine was now passed naturally into the bath without pain. The wound was cleaner. On the 15th there was a reduction of the temperature to below 100°: there were fæces in the vaginal wound. On the 19th the patient was making satisfactory progress. There was still a small quantity of fæces in the vagina. The temperature was about the normal line. The wound was much cleaner and was granulating. A number of bruises over the left hip were apparent. On the 31st the bath was discontinued as the wound was now cleaner and was granulating nicely. No fæces passed into the vagina and there was only a little discharge from the vagina. There was no pain. The general condition of the patient was very good. She left the hospital on Sept. 11th with the wound entirely healed; both urination and defecation were performed without any hindrance.

On April 20th, 1898, the patient was again brought up to the hospital complaining of having experienced severe pain for the past three days in the lower abdomen which was swollen, and there was some difficulty in micturition. The temperature was 102·8° and the child looked decidedly ill. On examination on the 21st there was a hard, rounded swelling on the left side of the mid-line below the umbilicus and per rectum this was felt to be nodulated and elastic, evidently containing fluid and reaching down to the level of the bottom of Douglas's pouch. The genitals gave evidence of the old injury. The lower part of the vestibule was a contracted fibrous ring into which the little finger would not go; the urethral orifice was within this and after some difficulty a *small* catheter was passed into the bladder, drawing off urine but without influencing the size of the swelling although it did not seem quite so prominent. As the instrument went in it was felt to pass over, as it were, tough fibrous ridges transversely placed on the upper wall about the neck of the bladder. In the vagina a sequestrum about three-quarters of an inch long was discovered and it was removed; it was a portion of the descending ramus of the pubes.

As the swelling seemed probably an abscess in front and to the left side of the bladder, a sequel of her previous accident, an operation was at once proceeded with, the patient's temperature at the time being 100·6°. An incision was made on the left side starting just above the pubes and at the outer margin of the rectus and passing along the line of the inner half of the inguinal canal. On dividing the external oblique the round ligament was exposed and it was seen to be imbedded in inflammatory infiltration. On cutting carefully through this matted tissue just above the ligament into the floor of the canal a cavity was opened of about the size of an orange from which very fœtid pus escaped with three small sequestra. The cavity had rather thick, well-defined walls and its floor was over and included the upper part of the left pubic arch and lay above and to the left side of the urethra as proved by the passage of the catheter. In the bone were some small pits from which the sequestra had come. The space was washed out with boric lotion and a drainage-tube was put in. It was dressed with cyanide gauze. The purulent collection was situated in the prevesical space (cavum Retzii) above the superior layer of the triangular ligament and to the left side of the urethra and had formed in relation with the necrosis of the arch secondary to the injury. The sequestrum found in the vagina had exfoliated from the pubes below the inferior layer of the ligament and thus the attachment of both layers of the ligament separated the sites of the necrosing fragments and accounted for the non-communication of the vagina with the abscess cavity.

The after progress of the case was uneventful. The temperature immediately dropped to normal and there was no further interference with micturition. The drainage-tube was removed on April 29th and the child went out with the wound healed on May 4th.

The first point to comment upon is that at the time of the injury, although it was strongly suspected, there was no evidence of any fracture of the pubic arch. In the light of what happened it is highly probable that there was a fissure with some splitting of bone which slowly exfoliated. This necrosis was attended by the formation of the very localised tumour in the front of the bladder. It was curious how the superior layer of the triangular ligament separated the two necrosed fragments and completely shut in the pus collection below.

Upper Wimpole-street, W.

VANISHING TUMOURS.[1]

BY D'ARCY POWER, F.R.C.S. ENG.,

SURGEON TO THE VICTORIA HOSPITAL FOR CHILDREN, CHELSEA;
ASSISTANT SURGEON AND TEACHER OF SURGERY AT
ST. BARTHOLOMEW'S HOSPITAL.

I WISH to deal in this paper with a phenomenon which has not yet, I think, received adequate attention though it must have been repeatedly observed by nearly every surgeon. The phenomenon to which I refer is the disappearance of a tumour which sometimes takes place after such slight surgical operations as incision, puncture, or even simple exposure. For the sake of convenience I venture to speak of these swellings as "vanishing tumours," for this character of spontaneous disappearance is really very startling and though it is satisfactory to the patient it is somewhat disconcerting to the medical practitioner for it nearly always falsifies his prognosis.

I would say at the outset that a "vanishing tumour" is not to be confused in any way with a phantom tumour, for it is in every respect a true swelling, visible to the eye, apparent to the touch, and capable of exposure by the ordinary surgical methods; occurring at any age and in either sex; most often innocent but sometimes, as I hope to show, undoubtedly malignant. My attention was first called to this form of tumour by the following case.

CASE 1.—A boy, aged eight years, was brought to me a few years ago suffering from a large cystic lymphangioma which occupied the whole of the left side of the neck, reaching upwards behind the pinna of the ear, the lobule of which it had invaded, and extending across the middle line in front of the neck. The swelling had been noticed directly after birth and it had been tapped before I saw it about 150 times with a trocar and cannula. It had not undergone much change in size and though it did not increase proportionately to the growth of the boy it got no smaller. The tumour consisted of an elastic and slightly lobulated tissue to which the skin was closely adherent. It clearly contained many cysts varying greatly in size and tenderness. With a full appreciation of the difficulties to be encountered I advised that the tumour should be removed and in due course I extirpated as much of it as lay in the posterior triangle of the neck. The wound healed by first intention and without any trouble except for a sharp attack of lymphangitis about a fortnight after the operation, due to a long railway journey home in frosty weather.

I saw the boy two months after the operation and found that the posterior triangle was free from growth but that the tumour still extended obliquely from the lobe of the ear which it involved, tilting it upwards across the neck to the second or third ring of the trachea on the right side. The swelling was greater at the lower than at the upper part of the neck. Five months after the operation the boy had a second attack of lymphangitis in the tumour and in the following month he had a third attack. After each attack the swelling seemed smaller. He was brought to me again nine months after the operation with the information that the tumour had vanished. I examined the neck carefully and found that the left anterior triangle was so soft that the beating of the carotid artery could be clearly felt and there was no trace whatever of the former swelling. I have seen the boy several times since, but there is no return of the tumour and the two sides of the neck are now quite symmetrical.

Microscopical examination of the piece of tumour removed showed that it consisted of a number of cysts formed of dilated lymphatics. The cysts had no very definite walls and irregular tags of connective tissue projected into them in many places. I should not have been at all surprised therefore if the tumour had consolidated into a mass of fibrous tissue or if the many small cysts had fused into a single large one. But I was distinctly taken aback, though the sensation was a pleasurable one, to find that the swelling, which was of very considerable size and extremely unsightly, had vanished so completely as to leave healthy and supple skin without any underlying induration.

CASE 2.—This case is an equally remarkable one and does not seem to be easily capable of an explanation. A girl, aged one year and ten months, was admitted into the Victoria Hospital for Children at Chelsea under the care of my colleague, Dr. J. W. Carr, on Nov. 1st, 1898. She had been ailing for six months, suffering at first from whooping-cough and afterwards from bronchitis and diarrhœa. During the week before her admission to the hospital she had been getting worse, being feverish, sick, and passing dark-coloured and slimy motions which contained blood, whilst for the last day or two her mother had noticed that she had been getting yellow. The other children were healthy and there was no history of syphilis to be obtained, but a brother and a sister of her mother—i.e., an uncle and an aunt of the patient—are patients in the Brompton Hospital for Consumption. The ward-note states that on admission the child was fairly well nourished, with a pale-yellow complexion and yellow conjunctivæ, the skin of the body generally being rather pale. The liver was enlarged and a little tender and its edge could be felt about an inch below the costal margin. All the other organs appeared to be healthy. The temperature was 102·2° F. Four days later the jaundice was deeper, the abdomen was distended, and the liver was rather larger, for it now reached about one and a half inches below the costal border of the ribs, the upper limit of the liver dulness being on a level with the sixth rib. After an interval of another four days a note was again made that the liver was considerably larger, for its lower border could be felt just above the level of the umbilicus, the upper limit being, as before, in the sixth space. The stools were almost white, but they were less offensive than they had been. Three days later, on Nov. 11th, the liver was said to be still larger, and it was undoubtedly tender when pressure was made over it. The upper limit was the sixth rib, the lower border was on a level with the umbilicus or a little below it. The stools were formed and were of the colour of white clay. The temperature was becoming hectic, oscillating between 102° and normal. On Nov. 15th, and again on Nov. 18th, the notes repeat the statement that the liver maintained its large size and that the jaundice was still present. The child was handed over for surgical treatment on Nov. 22nd in the hope that an exploration of the liver might afford her some relief and on the same day I opened the abdomen in the upper part of the right semilunar line. The liver was much congested but its surface was perfectly smooth and free from any adhesions. I passed a trocar and cannula deeply into its substance in three different directions as I thought it possible that there might be an hepatic abscess, but blood alone issued from the punctures. The lower border of the liver was then examined and a cystic swelling was felt which at first I took to be the gall-bladder, for the liver tissue was firmly adherent to it and was so thin that a part of the cyst projected through it at some distance away from the edge. A closer examination showed that the apparent cyst was in reality part of the small intestine which was so densely adherent to the liver that it was not thought advisable to separate them. The abdomen was closed and the child was said to have suffered very little from shock, the pulse being almost, if not quite, as good at the end as it was at the beginning of the operation. The temperature fell to 96·2° in the night and though it rose on the following day it was never more than 100° during the rest of the patient's stay in the hospital. The abdominal wound was quite healed on Dec. 2nd and it was noted on that day that the liver was not quite so large, though it was still very tender. On Dec. 9th the liver reached about one and a half inches below the costal margin, extending well over to the left of the middle line, but the tenderness had disappeared. On the 13th the liver was still smaller and on the 30th its lower border could no longer be felt beneath the ribs. The patient was allowed to get up and was walking a little by herself on Jan. 17th, 1899, and on the 24th as the liver appeared to be of its natural size and the abdomen was quite soft she was discharged from the hospital.

---

[1] A paper read before Harveian Society of London on March 2nd, 1899.

If it had not been for the remarkable and continued defervescence which followed the abdominal section in this case I believe that I should have regarded the shrinking of the liver as a simple coincidence, and that by accident I had done the operation at a time when the hepatitis had reached its maximum, but the range of the hectic fever had been so uniform and its cessation was so complete that I feel sure that the improvement was due directly to the operation.

I have had an opportunity lately of studying another vanishing tumour which was in St. Bartholomew's Hospital under the care of my chief, Mr. W. J. Walsham.

CASE 3.—A man, aged 21 years, was admitted into Harley ward with a tumour situated between the umbilicus and the pubes and apparently fixed to the pubes. It was three or four inches broad and of about the size of a large cocoanut. The swelling could be felt per rectum as a rounded mass moveable by the finger. The patient had been losing flesh lately, but his temperature was normal, his bowels acted naturally, there was no blood in his motions, and no pain on defecation; nor was there anything abnormal discovered in his urine or in the act of micturition. An incision was carried into the abdomen through the linea alba, when the tumour was found to be so fixed to the pelvis as to render its removal impossible. It was covered with large tortuous veins and was of a dark-red colour with the consistence of a soft solid. The wound was closed and united by first intention, the patient making an uneventful recovery. He was discharged with the swelling apparently in the same condition as upon his admission to the hospital or perhaps a little larger. Three months later he came back to the hospital and it was then found that the tumour had entirely vanished and that the patient had gained a stone and a half in weight.

Mr. Walsham in commenting upon this case[2] says very appositely that "it is of great interest as bearing upon the question of the occasional spontaneous disappearance of sarcomatous growths. It is, of course, possible that we were mistaken in our diagnosis and that the tumour was not sarcomatous. Its rapid growth, firm connexion with the pelvic bones, progressive loss of weight and strength of the patient, taken with the appearance and consistency of the swelling itself as revealed at the exploratory operation, led me to entertain no doubt as to its nature, and those of my colleagues who saw it with me were of the same opinion. This is the second case which I have personally met with of a supposed sarcoma in the abdomen disappearing spontaneously and several of my colleagues, I know, have had a similar experience. It may be added that there was no discharge of pus from the rectum, bladder, &c., nor any other sign of its having been an abscess or of an inflammatory nature; but of course one cannot lose sight of the possibility that it might have been an inflammatory or some other affection of the glands."

Mr. Walsham alludes to other cases of a similar character having been seen at St. Bartholomew's Hospital and I find the following in the Statistical Tables for the year 1897[3] as having occurred under the care of Mr. Alfred Willett who has kindly given me leave to publish details of the case on condition that I say that the patient was also seen by Mr. Bowlby.

CASE 4.—A man, aged 54 years, was admitted on account of an abdominal tumour and vomiting, both of two months' duration. He had also been losing flesh and was constipated. A hard nodular mass as big as a man's fist could be felt in his abdomen, lying just below the liver and slightly to the right of the middle line. It was well defined and was not particularly tender. An exploratory incision showed that the growth was adherent to the external abdominal wall in front, to the stomach and duodenum behind, and to the under surface of the liver above. The gall-bladder seemed to be quite surrounded by the new growth, which thus proved irremoveable and was thought to be malignant. The patient recovered rapidly from the operation and he left the hospital three weeks afterwards. He reported himself three months later to say that since the operation the swelling had "much dispersed." Four months afterwards he again came to the hospital and was examined at "consultations" by many of the surgeons, who agreed unanimously that no tumour could any longer be felt in his abdomen, and at this time the man seemed to be in good health. But a few months later he was seen by Mr. Berry, the surgical registrar, in another hospital, suffering from jaundice and emaciation and there was but little doubt that he had malignant disease probably in or near the head of his pancreas, a diagnosis which was confirmed after the death of the patient. Mr. Berry, to whom I wrote for further details of this patient, has kindly given me the following account of another case of a like nature.

CASE 5.—"A man was admitted into the Royal Free Hospital under Dr. Sainsbury and was seen by Mr. Boyce Barrow and myself. He had a rounded and hard lump as big as a fist in the region of his pylorus. We all thought it was malignant, although, from its smoothness and some other features I never felt sure that it was not inflammatory. I opened the abdomen and found some adhesions which I broke down. The man made an excellent recovery and lost all his symptoms of pyloric obstruction. Nothing more was seen or heard of the lump after the operation."

CASE 6.—The vanishing tumours to which I have referred hitherto have been innocent growths but this wax model and these drawings from the museum of St. Bartholomew's Hospital[4] belong to another category. They represent the top of the head and show a large flattened, irregularly-lobed tumour of the scalp lying over the interparietal suture. An area devoid of hair and measuring two inches in width by six inches in length, extending over the left parietal and frontal regions, marks the position of a former tumour which was removed by operation. Two flattened swellings are now seen near the scar and a third lies over the left frontal region. The patient was a man aged 24 years who at the time of his admission to the hospital in March, 1890, gave the following history. About six years previously he received a blow on the top of his head from the flywheel of an engine. He took no notice of the injury at the time but a tumour began to grow a few months later at the place where he had been hurt. It reached the size of a sparrow's egg and then disappeared in about six months. Six or eight tumours subsequently appeared on different parts of the head and then diminished in size. Another tumour appeared in September, 1889, and grew steadily but quite painlessly until it was removed in March, 1890, when it measured 10 inches in circumference. The scar caused by the removal of this tumour is seen in the model to lie over the left parietal bone. Microscopical examination showed the tumour to be a fibro-sarcoma, for it consisted for the most part of a round-celled sarcoma interspersed here and there with irregular connective tissue cells and in places with bands of fibrous tissue. The patient was under the care of Mr. Morrant Baker who applied the appropriate term

"withering sarcoma" to this rare specimen which is the more interesting because it was a well-known axiom with Cohnheim that "in the life-history of tumours there is only one fact of universal application—that a new growth never spontaneously recedes and disappears." Here, however, is a new growth which actually did recede and part of it disappeared, so that his generalisation is incorrect. And if it is incorrect for sarcomata there is no reason why it should not prove to be equally inaccurate for carcinomata. Indeed, there is very little doubt that carcinomatous ulcers of considerable size have been known to heal sometimes only superficially, the cancerous process continuing beneath the scar, but in some few cases the repair has been complete and permanent. Instances of atrophying scirrhus, too, are not uncommon in old and spare people, nor is the process difficult to explain in those whose tissues are undergoing nothing but retrogressive changes, since the cells have almost lost their power of reproduction.

There remains yet another class of vanishing tumours, but I am not concerned to speak of it at any length this evening, though it forms in some respects a pendent group to those which I have just mentioned. I mean cancers which disappear, or at any rate cease to show signs of active growth, after the removal of an ovary—hypertrophied prostates which become smaller when a testicle has been cut out or when the *vas deferens* has been divided and adenomata of the breast which vanish as a result of pregnancy and lactation. In these cases we shall have to look much further for the cause of the disappearance, because such tumours vanish as a result of a series of complex physiological changes about which we know nothing at present.

Mr. Stanley Boyd has recently called renewed attention to this class of tumour in his interesting and suggestive "Remarks on Oöphorectomy in the Treatment of Cancer of the Breast,"[5] and a similar case, brief notes of which follow, was under my care, conjointly with Dr. W. S. A. Griffith, last summer.

CASE 7.—The patient was in a state of advanced cancerous cachexia with a mass of scirrhus in one breast and symptoms of serious ovarian disease. On opening the abdomen both ovaries were found to be enlarged and cystic and the small intestine as it appeared in the wound was plainly the seat of metastatic deposits of cancer. One ovary and the breast were removed but no attempt was made to complete the operation by opening the axilla as the patient seemed to be too ill to bear any prolonged surgical manipulation. But she made a speedy recovery and she increased rapidly in weight.

I fully believe with Mr. Stanley Boyd that the removal of the ovary in this case was the direct cause of the retrogressive changes in the cancer. There must, however, be some physiological connexion between the two organs before such an effect can be produced, for I am not inclined to remove the testes for the cure of a cancer of the lip as a facetious and sceptical friend lately pointed out would be the proper and logical outcome of the hypothesis.

Many similar cases might easily be collected, but these are enough for the purpose which I have in view—viz., to draw attention to a class of tumours which either vanish spontaneously or after such comparatively slight surgical treatment as partial removal or exploratory incision. Many interesting points for discussion arise in connection with these tumours. Occasionally they are true sarcomata or carcinomata but they are much more frequently inflammatory swellings of the connective tissue and they occur, therefore, where the connective tissue is abundant in quantity and loose in texture. They are formed slowly and painlessly and they disappear in like manner. Yet being of considerable size and consisting of cells which are multiplying actively they may cause pressure symptoms and constitutional disturbances which make it hard to distinguish an innocent from a malignant tumour.

Now, the first point which I wish to raise is, What would have become of these tumours if they had been left alone? And it is to seek an answer to this question that has led me to bring this paper before the Harveian Society of London this evening for I think that many of the members may have seen such swellings and may perhaps have been somewhat more inclined to allow them to run their course unmodified by surgical interference. In the case of the lymphatic tumour (Case 1) I think that in all probability it might have remained another eight or 10 years, eventually shrivelling to become a wen or a soft fibroma. It might even have disappeared altogether and those who attended the last clinical meeting of this society will remember a very interesting case shown by your secretary, Mr. Raymond Johnson,[6] of a child with a cystic lymphangioma in the neck very similar to the one which I have described. No operative measures had been adopted, except puncture of the largest cyst, but the tumour was shrinking spontaneously in more than one direction. It was therefore getting steadily smaller and where it had shrunk the skin seemed to be perfectly healthy, whilst the underlying tissues were free from any induration. But the process of disappearance is a very slow one and the tumour in these cases is so unsightly as to make it quite worth the while of a child occupying a good social position to run the risk of extirpation, for no boy with such an hygroma could lead a happy life at a public school. Besides, one has no right at present to assume that they will disappear completely, for though the cysts may vanish I have seen thickened, warty, and ugly scars remain. But vanishing cysts are not confined to children; they occur sometimes in the breasts of women, and Mr. Bryant gives details of two cases which occurred in his own practice.[7]

The enlarged liver in Case 2 would, I think, have suppurated most undoubtedly. The inflammation was probably tuberculous and the *rationale* of cure was the same as in those cases of serous peritonitis which recover after simple incision and evacuation of the fluid. I do not know what would have become of the abdominal swellings. If no operation had been done they might still have disappeared or each might have formed an abscess. The connective tissue cells of the part were clearly in a very unstable condition and it is easy to imagine that under suitable conditions a sarcoma might have been produced. At any rate it is of the highest importance to know that such chronic and seemingly causeless inflammations can occur in the body. Presumably they may begin in gland or in epithelium equally with the connective tissue and if this be so and the infection of cancer with a predisposition to it happen to be in the body such an inflammation may be the determining cause of its local manifestation. Indeed, in Mr. Willett's case (Case 4) a patient with such a vanishing tumour actually died from cancer growing in the neighbourhood of his pancreas, where he had already suffered from an inflammatory swelling which had disappeared after his abdomen had been opened to find out its nature. The effect of surgical interference upon these tumours seems to be identical with that which takes place when any inflammatory swelling is incised. Tension is relieved and a series of complicated physiological changes are set up which end in resolution. We are ignorant as yet of the nature of these changes, but we assume them to be the direct outcome of alterations in the vaso-motor and trophic functions. The older surgeons set these changes in action by bleeding, for in this way they obtained a local effect by modifying the whole blood-pressure and it is certain that phlebotomy cured many obscure swellings. Blood-letting fell into disuse, but time, bringing with it improved surgical methods, has led us to cure by adopting similar means. Instead of drawing blood from the arm we now attack the part affected, even though it be placed where the most enlightened or reckless of our surgical forefathers would have considered it criminal to explore.

It is comparatively easy to understand how a simple inflammatory swelling may disappear, but it is very difficult to realise, much more to explain, the vanishing of a malignant tumour. Yet there can be little doubt that sarcomata, and in some very rare cases even carcinomata, do actually disappear. In a cancer such a disappearance seems to me to be quite inconceivable, unless we assume the disease to be one of an infective character in which the result as measured by the growth is in direct proportion to the amount of poison absorbed or manufactured within a body which is more or less predisposed to its action.

In speaking of these vanishing tumours I have mentioned in each case that they have been only partially removed or that they have only been looked at and not removed at all. I would *not* have it understood from this that I countenance or in any way recommend the partial removal of a tumour or that I think it is a desirable proceeding. Modern surgery, based as it is upon pathology, teaches most emphatically that tumours should be removed as completely and as early as possible and that the more a swelling is considered to be malignant the earlier and more complete should be the removal. But it has happened in these cases that from one cause or another so complete a removal was impossible, yet by accident or good luck coupled with some unusual modification of the morbid process the results obtained were most satisfactory though the method adopted was in the highest degree unsatisfactory if we look to the means rather than to the end.

ACTINOMYCOSIS (?) OF THE OMENTUM; DEATH FROM PYÆMIA.

BY HENRY HANDFORD, M.D. EDIN.,
PHYSICIAN TO THE GENERAL HOSPITAL, NOTTINGHAM.

THE interest of the following case does not depend solely upon the diagnosis. Whether actinomycosis or not the distribution and course of the disease are uncommon and the mass of new tissue is something quite unusual except in malignant disease which this certainly was not. I know of no other disease except carcinoma (scirrhus) in which such remarkable hardness of the new tissue is found. All the more common causes of inflammation and suppuration in that region were excluded at the post-mortem examination; but, indeed, none of them usually produce the amount of new tissue found in this case. The patient from his occupation had to do with corn and it is probable that he swallowed some to which the fungus was attached and that so the omentum was reached from the transverse colon. The general *coup d'œil* bore a striking resemblance to other cases which have occurred in this neighbourhood, but as the actinomyces was not found the diagnosis must remain non-proven.

The patient was a robust gamekeeper. At the end of August, 1898, he was suddenly seized with violent abdominal pain which lasted three days and did not return. He remained in bed a week. For the previous five weeks he had been going about, but had been unable to work. He was admitted into the General Hospital, Nottingham, on Oct. 4th complaining of loss of strength and weight. He then weighed 11 st. 4 lb., whereas six weeks previously he weighed 15 st. 3 lb. He had had severe diarrhœa which on admission had ceased. The most marked feature during the past fortnight had been repeated rigors during which his temperature ran up to 103° F. It was supposed that he might have some internal abscess and he was sent into the hospital for careful examination and watching. A most diligent search was made for any signs of suppuration in connexion with the appendix or with an impacted gall-stone but without success. At this time there was no pain or tenderness and the abdomen, which was large, could be palpated with the greatest freedom without revealing anything abnormal. The temperature was always febrile. For about a month he improved, regained a little weight, and got up. On Nov. 6th for the first time he was slightly jaundiced and the urine contained bile. It was gone in 24 hours and never returned to any great extent though he was a little yellow at the last. He now gradually began to complain of pain in the epigastrium. The abdominal muscles were held rather more rigid than formerly, but no growth could be detected. He was seen repeatedly by my surgical colleague, Mr. A. R. Anderson, both before and after his admission to the hospital, but no accurate diagnosis could be arrived at and there appeared no opportunity of successful surgical interference. By Nov. 24th the patient had become much worse, and as he was anxious that something should be done it was explained to him that his condition was desperate but that the abdomen could be opened to search for an abscess. If one was found the opening of it might relieve him. An exploratory laparotomy was performed by Mr. Anderson. It was shown that there were no gall-stones and no abscess in the superficial parts, but the tissues were so matted together that a full exploration was not possible, especially as the bleeding was free. The patient died on the next day and the examination post mortem showed his condition to have been quite irremediable either by medicine or surgery.

At the necropsy the intestines were found to be extensively adherent. The mesentery was somewhat thickened. The main mischief was in the transverse meso-colon which was of wooden hardness and from one to two inches thick. It was of normal colour and looked like ordinary dense fibrous tissue. There was general interstitial suppuration, scores of small abscesses, varying in size from that of a No. 1 shot to that of a pea, being found. There was a larger abscess nearer the head of the pancreas containing about two ounces of thick greenish pus. The pancreas, though enveloped in this new tissue, was itself healthy as shown by microscopic examination as well as by the naked-eye appearance. Behind the stomach was an abscess containing about three ounces of thick pus, which communicated with the stomach by a minute recent perforation. From the extensive ulceration and sloughing upon the outer (peritoneal) surface of the stomach and the uninjured condition of the mucous membrane around the perforation it was quite evident that the perforation had taken place in the unusual direction from without inwards. The microscopic examination also states: "The sections of the wall of the stomach show suppuration outside the muscular coat; perforation has probably taken place from without inwards." Behind the transverse meso-colon as well as behind the gastro-hepatic omentum several smaller abscesses were found. The liver was slightly enlarged and contained several pyæmic abscesses. There was also suppurating pylephlebitis. The gall-bladder contained normal bile. There was no stone in the gall-bladder or in any of the ducts. The portal fissure was occupied by a hard mass of similar colour and appearance to the rest of the new tissue and about two inches in diameter. The pressure of this no doubt caused the jaundice observed during the latter part of his illness. The other organs, including the intestines, were normal.

The origin of the disease appears to have been in the neighbourhood of the transverse colon which was completely hidden and embedded in the suppurating omental tissue. There was no malignant growth of the bowel itself. The true great omentum below the transverse colon was only thickened for two or three inches below the bowel. The great mass of new tissue was between the transverse colon and the pancreas and between the stomach and the liver. To the naked eye the new tissue bore the strongest resemblance to actinomycosis in its colour, its consistence in inflammatory fibrous tissue, its extreme hardness almost resembling wood, and in the interstitial suppuration. The characteristic granules were not found but the search for them was not prolonged as the examination had to be made late at night.

The microscopic examination showed no evidence of inflammation or malignant disease in the pancreas. The lesion in the omentum and transverse meso-colon was entirely inflammatory and there was nothing to show the cause of the suppuration. The tissue was chiefly fibrous. It bore no resemblance to carcinoma. Many sections were stained for actinomycosis but none was found. This is not very remarkable considering how troublesome the clubs are to stain in human actinomycosis and how sparsely scattered the fungus may be.

Nottingham.

ROYAL FREE HOSPITAL.—The seventy-first annual meeting of subscribers, governors, and others interested in this hospital was held at the hospital in Gray's-inn-road on Feb. 22nd, the Hon. Mr. Justice Bruce, chairman of the committee, presiding. Among those present were Captain Jessel, M.P., Mr. Charles Burt, Dr. Samuel West, Mr. James Berry, Dr. Elizabeth Blackwell, and Mrs. Garrett Anderson, M.D. Paris. In moving the adoption of the report the chairman said that the committee considered that the time had come when a commencement should be made in carrying out the urgently needed building improvements referred to in the report—viz.: (1) the alterations and additions to the ward lavatories, sculleries, and bathrooms; and (2) better accommodation for the nursing staff. With regard to the latter it was proposed to build a fourth storey over the side portions of the central block, which would provide separate bedrooms for 27 sisters and senior nurses, an enlarged sitting-room, additional bathrooms, &c. The estimated total cost of these works is £8500, towards which the sum of £2870 is available.—Before the close of the meeting the Earl of Stamford was appointed to fill the vacancy of Vice-President caused by the death of the Earl of Lathom.

UNIVERSITY COLLEGE HOSPITAL.

A CASE OF OPHTHALMIC HERPES WITH HYPOPYON-KERATITIS.

(Under the care of Mr. Percy Flemming.)

A man, aged 54 years, went to the casualty department of University College Hospital on Nov. 16th, 1898, on account of a burn of the head received in a gas explosion. He was treated by the house surgeon and 14 days later he was sent to the eye department as the eye had become inflamed. When Mr. Flemming first saw the patient on Nov. 30th his head was enveloped in bandages down to, and including, the eyebrows. The right eye showed much conjunctival redness with a little muco-purulent discharge. At the lower and inner part of the cornea was a small ulcer with a distinctly infiltrated edge; the anterior chamber was deep, the aqueous humour was turbid, and the iris was rather muddy. There was no hypopyon and nothing abnormal was found in the lacrymal sac. The bandages were not removed from the head and it was considered that the case was one of infective ulcer of the cornea due to the burn in the first place and to the state of the conjunctiva in the second. The patient was admitted into the general ward, the conjunctival sac was thoroughly irrigated with warm boric acid lotion, the lids were painted with nitrate of silver solution (10 grains to the ounce), and atropine drops and a quinine mixture were prescribed. The eye was not bound up. Two days later the ulcer had spread both superficially and deeply and there was a small hypopyon. On Dec. 3rd the lids were again painted and the ulcer itself was touched with pure carbolic acid; it was noticed that the patient seemed to feel very little pain when this was done. On the 5th the note states that the ulcer was cleaner but possessed still a well-marked infiltrated edge. A quinine lotion was ordered and the eye was bandaged. By the 8th the hypopyon had increased considerably and the ulcer had spread still further. There was still a good deal of conjunctival secretion and the lids were again painted with nitrate of silver and the eye was again bandaged. On the 10th Mr. Flemming for the first time saw the head dressed and it was then evident that in addition to the injury the patient was suffering from an attack of ophthalmic herpes. The right half of the forehead was red, the redness extending into the scalp, but being sharply limited by the middle line; there were several recent scars over this red area. Inquiry now elicited the fact that the patient had had much neuralgic pain over the right side of his head for some days previously to the accident, on account of which he first went to the hospital. Sensation was diminished but not abolished over the right side of the forehead and on the right eyeball. As soon as the "trophic" nature of the case was recognised the nitrate of silver was discontinued and the eye was kept firmly bandaged with a pad soaked in quinine lotion, but matters did not improve and four days later the ulcer had spread still more and the anterior chamber was quite one-third full of pus. On the 15th Mr. Flemming sutured the lids together, previously paring their edges for about the middle two-fourths of their extent. Union did not take place This was partly due to the fact that the patient, to use his own expression, "worked the eye well about" under the bandage. On the 20th, therefore, the lids were re-sutured and the stitches were removed four days later, good union resulting. The patient left the hospital on Jan. 4th, 1899. At this time it was quite possible to examine the surface of the cornea by making the patient look well to the right or left, the lids being separated at the inner and outer canthi. The ulcer had quite healed and no hypopyon could be detected. By the 7th the adhesions had stretched a little and it was possible to make a more thorough examination. There was no trace of hypopyon and the surface of the cornea was smooth. The pad and bandage were discontinued on the 23rd and the patient returned to work early in February still having the lids united.

Remarks by Mr. Flemming.—The interest and value of this case consist, I think, in the evidence which it affords respecting the efficiency of suturing the lids in cases of neuropathic keratitis. Looked at from this point of view it may almost be regarded as a crucial experiment. When the eye was first examined the nature of the case was overlooked, the dressing and bandages applied by the house surgeon concealing the skin eruption. When it was discovered that the patient was suffering from ophthalmic herpes the keratitis had spread and there was an extensive hypopyon, and I confess to having had some misgiving when I decided to suture the lids and tie the eye up. But under this treatment the inflammation promptly subsided and the hypopyon disappeared. To guard against a relapse the lids will be kept united a few weeks longer. On the other hand, the failure of treatment conducted on the ordinary lines for infective ulcers is equally striking. Further, the inefficiency of simple bandaging in these cases is shown, for the eye was treated in this way a few days after admission. Protection by pad and bandage is not effectual in keeping out particles of dust and fluff. I discussed the pathology of these cases in a paper published in The Lancet of July 2nd, 1898, and the occurrence of pain and iritis with a deep anterior chamber in this case lends some support to the views there expressed. If, as some suppose, these cases of neuropathic keratitis are merely examples of bacterial invasion of tissues, made prone to such invasion by being deprived of their nerve-supply, one would hardly expect healing to occur when the lids are sutured, the conjunctiva being inflamed at the time. In the paper previously mentioned the suggestion was made that the perverted nerve action resulted in an increase and alteration of the fluid secreted by the ciliary body, and in a similar way may perhaps be explained the conjunctivitis in this case. Suturing the lids seems the most efficient way of protecting the eye and the cornea is at the same time kept warm and moist and the healing process is thereby greatly favoured. This case further illustrates the fact that cases of ophthalmic herpes are apt to be overlooked and mistaken for other conditions. But attention to the unilateral character of the herpetic eruption should prevent mistakes being made. Probably the errors in diagnosis arise from ignorance of the existence of such a disease as "shingles of the brow" and this is one reason for publishing this case.

HUDDERSFIELD INFIRMARY.

TWO CASES OF ABDOMINAL SECTION IN WHICH UNUSUAL PATHOLOGICAL CONDITIONS WERE MET WITH.

(Under the care of Mr. S. Knaggs and Dr. E. A. Wright.)

The existence in the first case recorded below of an irreducible inguinal swelling and the history of a hernia fully justified the diagnosis of a strangulated hernia when signs of intestinal obstruction appeared; and indeed the diagnosis of suppurative peritonitis is not rarely a matter of great difficulty, for even when the abdominal cavity contains a large quantity of pus distinctive signs of peritoneal inflammation may be conspicuously absent. In the second case the puckering of the intestine appears to have been the cause of the intestinal obstruction and Dr. Boyd's explanation of the mode of its occurrence is probably correct. Both cases are of much interest and are well deserving of publication. For the notes of the cases we are indebted to Dr. Robert Boyd, senior house surgeon.

Case 1. *Perforative appendicitis simulating a strangulated hernia in a patient the subject of congenital hernia.*—A well-developed youth, aged 19 years, was admitted into the Huddersfield Infirmary on Oct. 11th, 1898, under the care of Mr. S. Knaggs. The patient previously to Oct. 6th enjoyed good health but he had had from infancy a congenital left inguinal hernia. He had not worn a truss for this for some years and had suffered no inconvenience from it at any time. On the evening of the 6th while in bed he complained of pain in the abdomen shooting to the umbilicus. Shortly after this he began to vomit greenish fluid and partially digested raw apples, of which he had partaken freely during the day. The pain and vomiting continued during the night. The bowels were moved slightly in the morning, a constipated motion being the result. No medical man was called in until the 9th, fully two days after the illness began. The patient's condition then was that of one suffering from acute abdominal trouble. He had been vomiting brown frothy material which had a distinctly feculent smell. The abdomen was distended and some dulness was present in the left iliac region. There was what appeared to be a hernia in the left inguinal region. It was painful on pressure, could not be reduced, and gave no impulse on coughing. The temperature was 101° F. and the pulse was 120, hard, and wiry. The symptoms, both local and general, pointed to a left inguinal strangulated hernia. As the parents refused to have any operation performed palliative treatment was adopted until the 11th—i.e., five days after the onset of the attack. The patient was then admitted into the Huddersfield Infirmary. His condition was grave. There was persistent feculent vomiting, the tongue was dry, and a thick brown fur covered the dorsum. The temperature was normal and the pulse was 120 and feeble. The abdomen was distended, tympanitic in front, but dull in the flanks. There was complete absence of pain except on pressure at the umbilicus and over a tumour in the left inguinal region. On examining the tumour no impulse could be detected on coughing. It could not be reduced into the abdomen and was dull on percussion. The bowels were slightly moved by enema on the day of admission but no flatus had passed since. The only hope lay in an immediate operation and the hernia was cut down upon, but as there was considerable difficulty in getting through the sac the abdomen was opened above the internal abdominal ring, the intention being to examine the internal ring from within. The whole abdominal cavity was found to be filled with pus. No hernia was detected in the left inguinal canal although there was a hernial sac. The patient's condition admitted of little more than washing out the abdomen and draining it. His death which seemed almost a foregone conclusion occurred some five hours later.

Necropsy.—The post-mortem examination revealed a ragged ulcerated perforation in the vermiform appendix. A small hard nodule of fæcal material was found close to the appendix and had evidently escaped through the perforation and lodged in the peritoneal cavity. The abdominal cavity was in a condition of general septic peritonitis. The hernial sac on the left side was half an inch thick and communicated with the abdomen by an aperture admitting the little finger. The sac was filled with pus from the abdomen.

CASE 2. *Intestinal obstruction.*—A married woman, aged 52 years, was admitted into the Huddersfield Infirmary on Nov. 16th, 1898, under the care of Dr. E. A. Wright. She exhibited the usual signs of intestinal obstruction and there was a history of illness of five days' duration. The attack commenced whilst the patient lay in bed. She had always enjoyed fair health in the past. The case on examination was deemed so urgent that an immediate laparotomy was performed. At first no definite lesion could be found, but a piece of dark claret-coloured intestine close to the cæcum was discovered. The mesentery corresponding to this piece of bowel was also deeply injected and embedded in it was a calcareous gland. The intestine was thrown into a number of folds around this point but no actual obstruction seemed to exist. On removing the gland, however, the intestine appeared to liberate itself as evidenced by the intestinal contents passing on. The wound in the mesentery made after removing the gland gaped about two and a half inches, showing that some traction had been exercised by the mesentery on the intestine. The patient died soon after the completion of the operation.

Necropsy.—At the post-mortem examination the interior of the affected piece of intestine was found to be studded with a few small ulcers, showing that some interference with the nerve- and blood-supply of the intestine had taken place there. This was probably due to the nerves and blood-vessels being slowly pressed upon in the contracted piece of mesentery.

Remarks by Dr. BOYD.—The notes on the above cases may serve to give some idea of the difficulty in diagnosing rare and peculiar forms of intestinal obstruction. In Case 1 the obstruction seemed to depend on the presence of a strangulated hernia but was discovered later to be due to general septic peritonitis consequent upon perforation of the vermiform appendix. Here, then, a patient who was the subject of a left congenital hernia suffered from perforative appendicitis with its accompanying results simulating a strangulated hernia. The diagnosis might have been more accurate had a medical man seen the case at the outset. There might then have been local signs of appendicitis, but when the case was seen all local signs were masked by the general condition. In Case 2 the cause of the obstruction was not very clear but was thought to have some relation to a mass which could be felt per rectum on the brim of the pelvis. This idea turned out to be correct, but the mode in which the obstruction was brought about is so rare that I thought it would be interesting to place the facts on record. The case may be classed under the head of obstruction from what Fagge in his "Practice of Medicine" describes as contractions. He gives a list of 12 cases taken from Guy's Hospital Reports, but among these only three correspond with the above case. The mode of obstruction is peculiar from the fact that a definite point cannot be located beyond which the intestinal contents cannot pass. The obstruction is not produced by narrowing of the lumen of the gut but by the intestine being gathered into folds and one fold above pressing into and obstructing the lumen of the intestine below. This mechanism taking place at several points in a foot or more of intestine causes the obstruction. I have demonstrated this by taking a piece of small intestine with its mesenteric attachment and gathering the mesentery together. The intestines were immediately thrown into a number of folds and a condition of mechanical obstruction existed. In carrying out this experiment I ran a stream of water through a piece of small intestine several feet long. On making traction on the mesentery the intestine was thrown into folds and the water ceased to pass along the intestine, even although some pressure was made on the loops of bowel. On releasing the mesentery the obstruction was relieved and the water continued to run as before. I am indebted to Mr. Knaggs and Dr. Wright for permission to publish these cases.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Extirpation of Aneurysms.

A MEETING of this society was held on Feb. 28th, Mr. BRYANT, President, being in the chair.

Mr. W. J. WALSHAM read a paper on a case of Extirpation of a large Non-pulsating Aneurysm involving the Common, Internal, and External Carotid Arteries of the Right Side of the Neck, with remarks on Non-pulsation in Aneurysms and the Treatment of Aneurysms by Extirpation. The patient, a strong, healthy-looking man, 49 years of age, had noticed a small swelling for six years on the right side of his neck. It had grown slowly and without pain until a few months before he came under observation, since which time it had got rapidly larger. The swelling extended from the angle of the jaw nearly to the clavicle and from near the middle line in front passed deeply beneath the sterno-mastoid muscle. It was roughly globular in shape and generally hard in consistency but soft and fluctuating in places. The skin was not adherent and the swelling had no connexion with the larynx or bones. There was neither pulsation nor bruit and nothing escaped on puncture with an exploring syringe. It was thought that the swelling was glandular and probably malignant. An exploratory incision was made and the tumour discovered to be an aneurysm. No pulsation was detected at the operation. The common carotid was ligatured in two places below the sac and divided between the ligatures, the sac was dissected up, collateral vessels entering it were secured as met with, and finally the internal carotid was ligatured above. The sac was then removed entire. The patient made a good recovery. Mr. Walsham observed that non-pulsation in an aneurysm, except when it had become consolidated, diffused, or inflamed, appeared to be rare, only a few cases having been found recorded in literature. The cause of non-pulsation in these was not very evident, but was attributed either to leaking of the sac or to blocking of its mouth with clots. Nine cases of extirpation of carotid aneurysms were quoted, all the patients recovering. The wider question of the treatment of aneurysms by extirpation was next discussed and a table of 33 cases of spontaneous aneurysms treated by extirpation was appended. The chief methods of extirpation employed were—(1) the old operation of opening the sac, turning out the clots, and securing the artery above and below; (2) the old operation plus the removal of the sac by dissection; and (3) the removal of the sac after the artery had first been tied above and below. The last method, slightly modified as in Mr. Walsham's case by dividing the proximal artery between two ligatures, dissecting up the sac, and finally tying the distal vessel, was submitted as the ideal method of extirpation. The conditions most favourable for extirpation appeared to be—(1) where there was insufficient room to apply a ligature to the artery on the proximal side or where the application of a proximal ligature was attended with great risk as ligature of the innominate for subclavian aneurysms; (2) where a number of large vessels communicated with the sac; (3) where other measures had failed to cure the aneurysm, (4) where the aneurysm, as in the popliteal artery, had become diffused or rupture of the sac or gangrene of the limb was threatened; and (5) where the setting free of emboli, as in carotid aneurysms, would be attended with risk of cerebral softening. From a review of the 32 cases and from the experience gained in his own case Mr. Walsham held that it was shown that the operation of extirpation might be looked upon as a most successful method of treating an external aneurysm and was perhaps the best that could be adopted in the conditions above mentioned. But for an ordinary popliteal aneurysm without complications enucleation could not be such a simple or satisfactory procedure as ligature of the popliteal or even of the femoral artery at the apex of Scarpa's triangle.

Mr. R. J. **Godlee** mentioned an unpublished case under his care in which he excised the sac of a popliteal aneurysm. Ligature of the femoral artery at the apex of Scarpa's triangle was first performed, but as the pulsation returned extirpation of the sac was performed. As a tourniquet could be used there was not the trouble with hæmorrhage met with in Mr. Walsham's case The enucleation was by no means easy, as there were many vessels coming out of the sac and there was great difficulty in freeing the sac from the vein The operation was not at first satisfactory as there was much anxiety owing to the amount of œdema of the foot. Recovery was slow, it being several months before the patient could return to his occupation. The difficulties met with in this case made him disinclined to advise enucleation as a routine treatment for popliteal aneurysm The condition of the artery must be ascertained as it would be most difficult to deal with the artery if it was much calcified. With reference to the cause of non-pulsation in some aneurysms Mr. Godlee suggested that one possible cause was from part of the aneurysm pressing on the artery below.

Mr. **Holmes** referred to a paper which he published in the St George's Hospital reports many years ago in which he attempted to account for the occasional want of pulsation in aneurysms. In one patient mentioned in that paper there was a tumour in the loin supposed during life to be either a renal tumour or an aneurysm. There was no pulsation and no bruit could be heard over it. It proved to be an aneurysm communicating by a very small aperture with the abdominal aorta. Another case was that of a man admitted for a fluctuating, non-pulsating tumour in the groin supposed to be a psoas abscess It proved itself to be an aneurysm by rupturing, and it was found to have arisen from the abdominal aorta and to have tracked down to the groin A bruit was often not detected because the nature of the case not being suspected it was not listened for. Nevertheless, in a number of cases it was certainly absent. Pulsation might be prevented by the aperture of the aneurysm being blocked by soft clot and so preventing the free exchange of blood to and from the artery. The size of the aperture would also affect the production of a bruit, as could be shown by imitating a bruit with the lips If too large or too small an opening were made the sound could not be reproduced. He considered that the plan of treatment pursued by Mr. Walsham in his exceptional case was the best which could have been adopted.

Mr. **Pearce Gould** related a case in which ligature was performed on one side and extirpation of the sac on the other. The patient was a man, a soldier, 28 years of age, whose right femoral was ligatured for popliteal aneurysm was discharged from the army and in January, 1898, he came under Mr. Gould's observation with an aneurysm of the size of an orange in the other popliteal space. Mr. Gould decided to excise the sac, but the dissection of the entire sac was found to be so difficult from the close adhesion to the vein that the portion of the sac in contact with the vein had to be left. The interest of the case lay in the fact that while pulsation had not returned in the right tibials six months after the ligature of the right femoral it returned on the left side on the thirteenth day after excision of the sac The man himself asserted that the discomfort from numbness and other signs of disturbance of the circulation was much greater after ligature The operation of excision when it could be easily and cleanly performed certainly gave rise to a minimum disturbance of the circulation but where there was extensive adhesion of the vein it must be a perilous method. He asked why Mr. Walsham thought it so necessary to remove the whole sac. What was the objection to ligaturing the main vessels and cutting away those portions of the sac which could be easily removed? Mr. Gould also mentioned the case of a man, 69 years of age, who was very apt to faint. He had a popliteal aneurysm and it was thought advisable to ligature the artery as the shortest operation. Gangrene, however, supervened and amputation had to be performed. Possibly if excision of the sac had been performed the limb might have been saved.

Mr. A. A. **Bowlby** had seen Mr. Walsham's patient and confirmed the statement that there was no pulsation of the tumour. He thought that there would always be a stage during the spontaneous cure of an aneurysm at which pulsation of the sac would be absent. Another factor was the diminution in calibre in the artery between the heart and the aneurysm which could be demonstrated in all museum specimens. Mr. Bowlby thought that this was due to the establishment of collateral circulation. As to the value of the operation of excision as opposed to ligature he thought that excision as a routine practice would expose the patient to unnecessary risk of bleeding and to injury of the vein. From observations on museum specimens he had satisfied himself that the artery near to a popliteal aneurysm was much more healthy than the artery higher in the thigh and that the ligature of the femoral at the apex of Scarpa's triangle was unnecessary. The ligature should be placed on the popliteal artery itself or on the femoral at the lower part of Hunter's canal

The **President** agreed that the operation was the best in the present case but did not think that it should be substituted for the old method. There was much risk of wounding the vein and he well remembered that the cases of popliteal aneurysm which went wrong were those in which the vein was injured and thrombosis had occurred. He had excised small aneurysms in the forearm, foot, and in two cases in the course of the brachial artery and he had tried to excise a popliteal aneurysm in one case of a man over 80 years of age The aneurysm had ruptured under the skin and the President first ligatured the femoral artery in Hunter's canal and then tied the artery on the other side of the sac and tried to excise the latter, but found it impossible to do so. The President emphasised the importance of examining for a bruit, as there might be a bruit even in a non-pulsating aneurysm.

Mr. **Walsham**, in reply, said that he believed that for ordinary cases dissection did not compare with ligature. In the case of popliteal aneurysm he agreed with Mr. Bowlby that the lower part of the femoral should be tied. He thought that if portions of the tumour and blood-clot were left that the risk of suppuration was greatly increased, and further that there was a risk of overlooking some collateral vessel the aperture of which might be only insecurely closed by blood-clot which might subsequently be dislodged and give rise to serious hæmorrhage.

MEDICAL SOCIETY OF LONDON.

Auto-Intoxication and its Relation to the Treatment of Disease.

A **meeting** of this society was held on Feb. 27th, the President, Mr. **Edmund Owen**, being in the chair.

Dr. **Sidney Martin** read a paper on Auto-Intoxication and its Relation to the Treatment of Disease. He said that in attached to the words "infection" and "intoxication," and by "infection" was meant the invasion of the body by a living germ which by itself or its products of activity injuriously affected the tissue, and by "intoxication" was meant the poisoning of the body by chemical agents usually the products of activity of the living germ. No definition of these processes could however be rigid and a typical example of "infection" was seen in anthrax when from the primary infection the bacillus invaded the body, and a typical example of "intoxication" in tetanus when the bacillus was localised to the seat of injury and the toxic substances were absorbed from this spot. In "auto-intoxication" the body manufactured its own poisons but the term comprised many different conditions, in some instances so widely different that he questioned the propriety of retaining the term. He described auto-intoxication under three headings: (1) auto-intoxication of gastro-intestinal origin; (2) auto-intoxication occurring in the course of chronic disease, such as chronic renal disease, diabetes, &c.; and (3) auto-intoxication occurring in association with the glands of the body, the thyroid, suprarenal pituitary body, and also with the liver, pancreas, and testicle. He pointed out that the activity of a tissue in disease might be altered and so produce symptoms in various ways—e.g., by interference with vascular and nervous supply, by the accumulation of products of its activity, by the preponderance in it of certain mineral salts, especially potash, and by the action on it of some poison of external or internal origin. It followed that the determination of the cause of the effect on the tissue might be difficult if not impossible; in other words, that what was observed as a symptom might be produced by many different causes which might throw an organ or tissue out of activity. A poison, he remarked, did not necessarily kill and, failing death, the final effect of the poison was in many cases the result of an action on various tissues and organs. This was particularly to be noticed with the poisons which acted in disease. In reference to auto-intoxication of intestinal origin the chief examples were ascribed to bacterial decomposition of the gastro-intestinal contents as distinguished from bacterial infection of the intestine. With the exception of the bacillus coli communis most of the intestinal bacteria were non-pathogenic. If, however, the products of putrefaction were absorbed the body was poisoned and this process frequently passed from one of intoxication to one of infection of the intestinal wall or of the peritoneum. He thought that intestinal bacterial intoxication should be grouped with the bacterial processes that occurred in disease and not as an auto-intoxication. Another form resulted from the indigestion of food, in which, in addition to the local symptoms, there were others described as remote or reflex. This subject was a very complex one and must be discussed in reference to auto-intoxication since during the process of digestion bodies were formed which possessed poisonous properties. He pointed out that normally in the process of absorption the albumoses were transformed by the mucous membrane of the stomach and gut into the proteids of the body, but it was quite possible that their occasional presence in the blood might account in part for some of the symptoms of disordered nutrition. Passing on to group 2 he observed that some of the cases must probably be ascribed to an auto-intoxication in which the poisons originated in the tissues of the body and were not due to bacterial activity. Although most of the proteid substances of the body were non-toxic some had a distinct physiological action, but it was quite possible that in disease some of the altered products might determine functional disturbances. He added that so far no poisons resulting from the splitting up of proteid or other body substances without the aid of bacteria had ever been separated. Discussing the nature of Bright's disease and diabetes he suggested that the symptoms of uræmia should be ascribed to the selective action of a poison or poisons on the cerebral centres. He referred to Bouchard's contention that in uræmia the normal toxicity of urine was greatly diminished, from which that observer inferred the retention of poisons in the body. The substances met with in diabetic patients which were not present in health were not very toxic and no poison had been isolated which would account for the phenomena though the occurrence of peripheral neuritis might be taken as evidence of an intoxication. He discussed cholæmia and anæmia from this point of view. He then passed on to consider the effects of removal of normal glands in respect of nutrition and their bearing on disease. The effects of their removal had, he said, been ascribed to the absence of an internal secretion which was normally given to the body and which was essential for the carrying out of certain physiological processes, or, on the other hand, the phenomena following removal might be due to the non-elimination of some poison inimical to life. In view of the well-marked physiological action of certain normal glands it was fair to suppose that in the normal body these glands formed substances as internal secretions which were essential to the maintenance of the complex physiological processes of health. But an excess of this very physiological activity might in itself be a determinative cause of disease.

The President after congratulating Dr. Martin on his paper said that he believed that rickets was a condition produced by auto-intoxication and that the poison probably arose from the gastro-intestinal tract. This condition had not been mentioned by Dr. Martin in his paper nor had the condition of peripheral neuritis following influenza. He mentioned two other conditions which he thought were due to auto-intoxication. The first was the sense of fatigue and headache which often occurred after unwonted exercise and the second was the disturbance of the renal function which sometimes followed massage.

Dr. Mott said that with regard to auto-intoxication as affecting the nervous system he had worked at the subject on bio-chemical lines. In general paralysis of the insane well-marked degenerative changes took place in the nervous tissues of the body leading to the formation of a fatty substance which stained black with osmic acid. He had estimated the comparative amount of phosphorus in the two sides of a spinal cord from a case of hemiplegia and he had found that the amount of phosphorus was diminished on the degenerated side. The myelin became broken up into glyco-phosphoric acid and a neutral fat. In order to test the toxic action of the cerebro-spinal fluid a given quantity of normal cerebro-spinal fluid was injected into an animal; no effect was produced. The cerebro-spinal fluid from a case of general paralysis of the insane was injected and caused a very marked fall of blood-pressure. It was then found that an injection of cholin gave the same results. The platinum salt of the same body crystallised out produced the same effect. It seemed therefore probable that cholin was the toxic agent in general paralysis of the insane and was formed by the breaking up of the phosphoric fats into a neutral fat and cholin, the cholin being absorbed into the cerebro-spinal fluid, and some of the effects of the disease might be caused by the venous stasis caused by that body. Cholin acted upon the muscle fibres of the vessels and caused dilatation of the splanchnic vessels. Although cholin was poisonous it was not nearly so poisonous as neurin which caused a rapid fall of blood-pressure followed by a rise in pressure and respiratory spasm resembling in its effects the poison muscarine. Glyco-phosphoric acid injected into the body gave rise to no toxic effects. In the class of cases above referred to the cause of death was not obvious, but on examination of the various organs—heart, liver, kidney, diaphragm, &c.—very marked fatty changes were found. This was especially marked after epileptiform convulsions. One case, a youth, aged 18 years, had been examined; he was in perfect bodily health till two days before death when he was seized with epileptic fits and passed into a condition of *status epilepticus* from which he died, and on examination it was found that extensive fatty degeneration of his viscera and muscles was present. Insufficiency of oxygen probably accounted for the presence of fat in the muscle.

Dr. Washbourn considered the title "auto-intoxication" misleading as it had been applied to two distinct conditions; firstly, the intoxication due to the absorption of substances living or dead from the intestine, and secondly to the condition met with in cholæmia, uræmia, and similar diseases. In the first group many of the cases were infective and in the second group there was still lacking the proof that they were due to the circulation of poison in the blood. With regard to protection against infection by the intestine it would seem to depend on some condition of the mucous membrane which prevented the passage of bacteria and it was only when the nutrition failed that bacteria and the poisons produced by metabolic processes passed through the mucous membrane of the intestine. It was well known that pathogenic organisms were often found within the body; for instance, the diphtheria bacillus was found in the throat giving rise to no toxic symptoms, and it suggested that the body possessed some power of inhibiting the functions of the bacteria. In reference to the various forms of intoxication occurring in disease of the liver and kidney it was pointed out that all the glands of the body possessed either a secretory, excretory, or metabolic function, and that the secretory and excretory glands had also a metabolic function and that it was probable that in uræmia the condition of the patient was not so much due to the retention of certain salts as to the altered nutrition of the cells of the kidney.

Dr. MARTIN replied.

The PRESIDENT announced that the Fothergill prize had been awarded to Dr. S. Monckton Copeman for his recent researches in connexion with glycerinated vaccine.

CLINICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Feb. 24th, the President, Mr. LANGTON, being in the chair.

Dr. PARKES WEBER showed a case of Re-commencement of Muscular Atrophy long after infantile paralysis. The patient was a lad, aged 17 years, who suffered from severe infantile palsy at the age of two years. About four or five months ago he noticed loss of power in the right hand and wasting in the right thenar muscles. The original disease in infancy affected both right limbs, the right side of the face, and probably also the left lower limb. As a result the whole right lower extremity was wasted and almost completely useless. It was possible that the paralysis of the right arm and right half of the face, from which the patient recovered, were due to a temporary affection of the cerebral cortex (polio-encephalitis of Strümpell) occurring simultaneously with the acute anterior poliomyelitis.

Dr. CAHILL showed a woman, aged 27 years, with Hypertrophy of the Right Breast due to pressure of the paralysed and contracted right arm. At the age of nine years she had right hemiplegia after diphtheria and the right arm became spastic and contracted, being firmly flexed and adducted so that the hand pressed on the thorax just above the mamma, and this breast had always been larger than the other. That this was due to the pressure was confirmed by the diminution which had taken place since the arm had been kept extended at night by a splint.—The PRESIDENT thought that the breast was not so much hypertrophied as displaced downwards by the arm.

Dr. H. A. CALEY showed a woman, aged about 40 years, suffering from Pulmonary Fibrosis associated with Tabes Dorsalis and Arthropathy. The patient first went to St. Mary's Hospital in October, 1896, with characteristic symptoms of tabes. As there was some cyanosis of her lips he examined her chest and found signs of pulmonary fibrosis, most marked on the right side, a cavity at the right posterior apex, and bronchiectasis at the right base. She had no cough or other pulmonary symptoms. There was a history of her having attended a hospital for chest trouble at the age of 13 years, and Dr. Caley thought that the chest trouble dated from then. In 1897 she developed painless effusion in both knees of the type described by Charcot in tabes. Dr. Caley regarded the association of the pulmonary and nervous diseases as purely accidental.

Dr. BERTRAM HUNT showed a boy, aged six years, suffering from Rheumatoid Arthritis with enlargement of the Spleen and Lymphatic Glands. While in hospital suffering from tonsillitis and broncho-pneumonia the knees and elbows became painful and then swelled. The effusion was not great and skiagrams showed that the bones were normal. There had been irregular pyrexia, the temperature sometimes reaching 104° F., progressive anæmia, enlargement of the lymphatic glands in the axilla and groins and considerable enlargement of the spleen. Bacterial examination of the synovial fluid gave negative results. Dr. Hunt thought that the joint disease had been secondary to the tonsillitis.

Dr. WASHBOURN and Mr. ARBUTHNOT LANE showed a woman from whom Mr. Lane removed a Tumour growing from the pia mater over the arm area two years ago. The case was recorded in the Transactions of the Clinical Society, vol. xxx., p. 164. Permanent paralysis of the right arm had followed the operation but she was otherwise in good health and there had been no recurrence of the fits from which she previously suffered.

Mr. C. E. MOUAT-BIGGS showed a young man suffering from Factitious Urticaria. The patient was a healthy athlete who had never suffered from urticaria from any of the usual causes, but remarkable urticarial wheals could be induced anywhere on his skin by drawing lines on it with any blunt instrument. A white wheal rose on a scarlet background forming an elevation of quite an eighth of an inch. This reached its maximum in five minutes and faded in the course of an hour. There was not the least itching or discomfort. Pressure alone brought them about. Some cases had been described in which similar wheals were produced by local cold such as that by ether spray, several of the patients having also paroxysmal hæmoglobinuria, but neither of these conditions existed in this patient.

Dr. RAYMOND CRAWFURD (with Mr. LOCKWOOD of Sheffield) showed a well-marked example of Myositis Ossificans Progressiva in a boy aged six and a half years. There were no traceable evidences of rheumatism in the family, though the child himself had disease of the mitral valve which presumably was rheumatic. Injury, as in so many cases, appeared to have been the direct exciting cause at two and a half years old. The bony growths for the most part seemed to have originated from the spinous processes of the vertebræ and to have spread into the retro-vertebral muscles, more particularly the latissimus dorsi and trapezius, the child's back being traversed in several directions by elevated ridges of bone. The fixed curvature of the spine and the rigidity of the cervical muscles gave the child a very characteristic attitude. The upper arms were glued to the sides by ossification of the humeral attachments of the latissimus dorsi on either side. Skiagrams were handed round to show the actual condition of the thumbs and great toes. The shortness of the thumbs was chiefly due to shortness of the metacarpal bones and their rigidity to synostosis of the first and second phalanges. In the great toes the metacarpal bone was completely united by bone to the first phalanx and the effort of nature to compensate this condition had resulted in a throwing outward of the ungual phalanx beneath the second toes.

Dr. LEONARD GUTHRIE showed a case of Myopathy in a child, aged four years. The disease appeared to have been congenital. The child had never been able to walk or stand. He could sit up, but easily fell backwards and was unable to rise. All the muscles were extremely weak, but in the arms he could perform most movements although feebly. In the legs there was almost complete loss of power. There was diminution of both faradaic and galvanic irritability but no definite reaction of degeneration.

Dr. GUTHRIE also showed a boy, aged six years, with Infantile Paralysis affecting Both Arms and also the Intercostal Muscles, so that the breathing was purely diaphragmatic. The legs were unaffected.

Dr. STCLAIR THOMSON showed a man, 36 years of age, complaining of Dysphagia and found to be affected with unilateral paralysis of the eighth and bulbar nerves. He had complained of giddiness and deafness for three years and a year ago he became hoarse and had difficulty in swallowing. On examination his left vocal cord was found to be paralysed. There was no œsophageal obstruction. Six months ago his palate became paralysed on the left side and taste was lost on the back of the tongue on that side. The pulse had been rapid throughout. There was no specific history, but considerable improvement followed a course of mercury and iodide of potassium.

Sir HUGH BEEVOR showed a case of Chronic Rheumatic Arthritis in a man, aged 60 years. It was almost confined to the metacarpo-phalangeal joints in either hand. The fingers were flexed to the ulnar side. This was attributed to the use of his hands in working the large "sweeps" of a barge.

Dr. HARRY CAMPBELL showed a case of Asthenic Bulbar Paralysis in a woman, aged 29 years, which he believed to be the fourth reported in this country. The paralysis was incomplete but became much aggravated if the muscles were used. Symptoms showed themselves 15 months ago, when she noticed that she had difficulty of utterance if she sang for a short time. At the present time all the muscles ordinarily concerned in bulbar paralysis were affected by this curious weakness and also the anterior part of the occipito-frontalis, and occasionally there had been loss of power in the arms when they had been raised for a time. The symptoms were always better in the morning after a night's rest. No lesion had been found in the brain in any of the recorded cases. There was no sensory change and the electrical reactions were normal.—Dr. J. A. ORMEROD said that he had seen an exactly similar condition affecting the upper muscles of the thigh in a man.

Mr. A. H. TUBBY showed a man, aged 65 years, suffering from Multiple Sarcomatous Tumours of the Skin. The primary tumour was in the upper part of the right side of the scrotum and was noticed six months before. A second tumour appeared on the left side and then one under the jaw. Now there were hundreds, some of them of considerable size, all over the surface of the body. The liver was enlarged and there was some jaundice.—The PRESIDENT referred to a similar case and commented on the small disturbance of the general health which such patients presented.

Mr. TUBBY also showed a child with an Anterior Congenital Dislocation of the Hip. He remarked that this form was more common than usually described, being present in one-third of the cases. It was uncertain whether the condition was due to intra-uterine dislocation or birth dislocation. In this case he had tried to replace the bone but had failed as there was no definite acetabulum.

EPIDEMIOLOGICAL SOCIETY.

Typhoid Fever.

A MEETING of this society was held on Feb. 17th, the President, Dr. FRANKLIN PARSONS, being in the chair.

Dr. BOOBBYER, medical officer of health of Nottingham, read a paper on Ten Years' Experience of Typhoid Fever in a Midland Town. In this, he said, his first aim was to show "the definite causal relation subsisting between the accumulation of organic filth in dense urban districts and the endemic occurrence of enteric fever." The labours of Pettenkofer in directing attention to the soil as the proper habitat of the typhoid poison, the discovery of the bacillus by Eberth, Gaffky, and Klebs, and the confirmation of Pettenkofer's doctrine by Dr. Sidney Martin's studies of the behaviour of the bacillus had brought order out of chaos, but there was still much to learn as to its life-history in relation to the endemic and epidemic prevalence of the disease. The reports of Sir R. Thorne, Dr. Bulstrode, and others showed that in this country there was a growing conviction that too much importance had been attached to the agency of water and milk as seen in occasional outbreaks to the neglect of the conditions on which typhoid fever depended in its annual and more permanent prevalence. After giving an account of the routine practice and of the provision of hospital accommodation in Nottingham and a full description of the physical and geological conditions of the district, the elevation of the different parts of which varied from 80 to 400 feet above the normal level of the river Trent, and which for the most belonged to the Bunter sandstone and red marls of the Trias, except on the south where the soil consisted of alluvium and gravels, he described the remarkable holes and caverns in the rock which were constantly met with in sewerage and building operations and which were frequently utilised as cesspits, the cleansing and filling up of which was often a work of considerable difficulty. Prior to the Act of 1845 there was within the limits of the ancient city a population of over 50,000 crowded on 927 acres of sewage-sodden, pervious soil. Extensive rookeries had been cleared by the railway construction now going on, the excavations revealing a depth of 30 feet of made soil, yielding relics of many centuries of occupation as did also the black, cheesy organic deposits which filled the ancient town ditch. The Borough Extension Act of 1877 brought in a number of villages and districts which were being rapidly built over, nearly 1000 houses having been erected in each year of late, many of them in the "Meadows," a low-lying district exposed to floods. From the year 1700 the water-supply had been drawn from the Trent till 1856, when a succession of borings were made in the rock at a distance from the town, which now enjoyed a supply of 21 gallons daily per head of excellent water. The sewers were all of modern construction and were well planned, the sewage (from 6,000,000 to 7,000,000 gallons daily) being conveyed to a farm of 1800 acres six miles away partly by gravitation and partly by pumping. But there were still only 10,000 water-closets; in 400 houses midden-privies were retained and the remainder were provided with 40,000 pails. The death-rate from typhoid fever was always above the mean of the "great towns," except in 1879, 1892, and in 1888, for the deaths in the early months of that year belonged properly to the great wave of the previous autumn. In these years the mean temperature of the summer and autumn was distinctly below the average and the mortality from diarrhœa was also very low, but there was nothing to be noted in the rainfall. No relation could be traced between the soil or elevation and the incidence of the disease; between altitudes of 100 and 300 feet above ordnance datum; or between the back-to-back houses in the city and the detached cottages of Radford. Poverty, dirt, overcrowding, soil-pollution, and retention of fæcal matters in privies or pails were the essential conditions. In one low-lying district where large quantities of "made soil" were deposited on the alluvium and gravel for the purpose of raising the site the incidence of the fever was increasing yearly. Here, too, the foul mud left behind after floods added to the pollution of the soil, but the portion of the Meadows to the south of the Trent, at the same level and on the same subsoil, enjoyed comparative immunity, the houses being of a better class and made soil not being used. Throughout the district 86 per cent. of the cases occurred in houses having five rooms or less and 14 per cent. only in those having more, though these latter constituted from 45 to 50 per cent. of the whole number. The incidence of the disease on houses with water-closets was one in 558, with pail-closets one in 120, and with midden-privies one in 87. It might be objected that the first were for the most part of a better class, but the difference between the two latter groups was striking and could not be thus explained, or otherwise than by the soil pollution inseparable from privy-middens which was aggravated by the frequent practice of depositing the filth during its removal on the ground, and perhaps again in the street before carting it away. Though the disease was not so highly infectious as scarlet fever or measles he was convinced that it was far more easily and frequently spread by personal intercourse than was generally believed. Uffelmann and Germano had shown that the bacilli retained their vitality for a long time when sufficiently dried to be blown about as dust, and he had had to investigate several outbreaks which could not be explained otherwise than by personal intercourse, the evidence of which was complete. In the general hospital 848 cases had been treated in 10 years, and 22 of the staff had contracted the disease, or 2·5 to 100 patients. In the same period there had been 157 cases in the children's hospital, 11 cases occurring among the staff, or 7·0 to 100 patients. He had thus at length overcome the reluctance of the authorities to provide for the isolation of what they had held to be a non-infectious disease. He had traced several outbreaks to contaminated milk, but none to shell-fish, notwithstanding the enormous consumption of mussels, &c., by the colliers. His conclusions were: 1. That a sustained mean temperature of over 55° F. usually preceded an autumnal rise in the prevalence of typhoid fever, a low summer temperature having the opposite effect. 2. That the disease was endemic in poor, crowded urban districts, irrespective of elevation or of geological formation wherever favourable conditions, especially soil pollution, were present. 3. That even in the presence of such conditions as made soil and pail-closets the better class of houses suffered less than the poorer similarly circumstanced. 4. That the incidence was heavier on houses with dry closets than on those with water-closets and among the former on those with middens than on those with pails, the difference being more marked the poorer the class of houses. 5. That it was directly communicable by personal intercourse even in well-arranged hospitals, and much more so in the confined dwellings of the poor.

The PRESIDENT remarked on the parallelism of typhoid fever and summer diarrhœa in their relations to temperature and on the immunity acquired by residents in insanitary localities. He thought that much harm was done by underrating the communicability of typhoid fever by personal intercourse.

Dr. SEATON felt that too much attention was directed to water as a means of spreading typhoid fever to the neglect of local conditions. There seemed to be no generally accepted method of dealing with typhoid excreta, but the life-history of the bacillus outside the living body offered a wide field for research that the Jennerian Institute would do well to take up.

Dr. WHITELEGGE had found the acclimatisation of the inhabitants of the poorer quarters to render vain his denunciation of the practice of building on made soil or over the rock caves; but he had often noticed that the occupiers of the better houses in such localities were attacked after their return from the seaside.

Dr. Bulstrode said that no one who had lived in a fever hospital could doubt the fact of personal infection. As to shell-fish it should be borne in mind that cockles were always cooked and mussels, &c., were frequently so, oysters only being habitually eaten raw.

Dr. Willoughby pointed out that typhoid fever when water-borne appeared as an epidemic or explosive outbreak, the endemic and annual recurrent prevalence being dependent on local and permanent insanitary conditions. He believed that with typhoid fever, as with cholera, personal infection was mostly the result of "eating with unwashen hands" after attending to the patient, which would account for its being almost unknown in private practice save in the confined dwelling rooms of the poor, and might explain its far greater frequency among the nurses in the children's hospital than among those in the general hospital as noticed by Dr. Boobbyer.

Dr. Theodore Thomson thought that too much importance had been attached by Dr. Boobbyer to the kind of closet, for in some water-closet towns, as Liverpool and Birkenhead, the typhoid fever death-rate was 0·36 and 0·32 per 1000, while in the midden towns of Bradford, Oldham, and Halifax it was only 0·16, 0·17, and 0·13 though he did not doubt that the former would be still worse with middens and the latter better with water-closets. The experiments of Dr. Sidney Martin and others on the growth of the bacillus in polluted soil were very instructive and should be followed up by local investigation of soil conditions generally.

Mr. Shirley Murphy pointed out the fact that the young nurses in the hospitals of the Asylums Board were attacked in much greater numbers than the older women in the London Fever Hospital. In London the local prevalence of typhoid fever was in direct proportion to that of poverty as shown in Mr. C. Booth's maps. The high death-rate in Liverpool might be due to the social habits of the large Irish section of the population.

Dr. Boobbyer, replying, observed that the water-closet houses were not exclusively of a better class, for all new cottages, being built now at the rate of 700 yearly, were thus provided; nor were those with privies the worst, they being mostly old houses of a fair class on the outskirts, none now remaining in the city itself. Pails were dangerous in the dwellings of the poor but not where they were used with due care, 1000 such houses having never been attacked. The treatment of the typhoid excreta recommended in handbills was that they should be absorbed by sawdust, disinfected with one in 1000 sublimate, and then burnt. He assured Dr. Bulstrode that the mussels so largely consumed by the colliers on Sundays were very rarely cooked, yet these people suffered less than those in some other quarters.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Cases.—Pylorectomy.—Vaginal Section.

A MEETING of this society was held on Feb. 23rd, the President, Dr. Macfie Campbell, being in the chair.

Mr. Hugh E. Jones exhibited patients on whom the operation of Discission of the Crystalline Lens had been performed for High Myopia.

Mr. Frank T. Paul submitted a case of Cholecystectomy for Gall-stones and Cancer. The tumour was a small villous carcinoma of the fundus of the gall-bladder which was removed together with the upper half of the organ and 13 gall-stones. The patient recovered from the operation in a few weeks, but in two and a half months died from enlargement of the liver, which was apparently not due to recurrent cancer but to some inflammatory condition probably set up by stones in the hepatic ducts.—Mr. Rushton Parker remarked that few operations were more gratifying to the surgeon and patient than the removal of gall-stones; he took it that Mr. Paul in this case excised the gall-bladder because it was discovered in the search for gall-stones to be cancerous. It appeared to be removeable and he was not thereby advocating the general removal of similarly affected gall-bladders as hinted at by one speaker.—Dr. Imlach, Dr. E. T. Davies, and Dr. W. Alexander spoke.

Mr. Robert Jones showed a case of Myositis Ossificans exhibiting unusual characters. The patient was a youth, aged 16 years, who came to him because of difficulty in flexing his knee, caused by a hard mass apparently attached to the upper two-thirds of the thigh, which interfered with muscular action. Further growths were found on the inner aspect of the right jaw below the ramus, a small lump below the right olecranon, thickenings at the insertion of the right ligamentum patellæ, and at each first tarso-metatarsal joint. His back presented an extraordinary spectacle. Over the spinous processes a continuous line of hard material, cartilaginous or bony, extended from the level of the fifth dorsal to the fourth lumbar spine. This central ridge bifurcated at the lower end, the extremities of the bifurcated portions almost reaching to the iliac crests. From the central ridge two transverse strips projected at the upper end and two at the lower, almost symmetrical in appearance. The upper ones arose about the level of the seventh dorsal and were about two inches in length, the lower ones at the level of the second lumbar, the right being about three inches long and the left two inches. These prolongations were moveable and the fingers could be placed under their tips. The patient was unable to stand absolutely erect from the fact that extension of the spine resulted in the jamming of structures in contact with the lower end of the prominence. Four years ago the patient fell on a doorstep and hurt his back; a year later the growth started in the centre of the spine. The origin of the tumour of the jaw cannot be fixed. The thickening at the elbow started after a blow and the tumour of the thigh had lasted four months. Mr. Jones proposed to remove the growth on the back and any other deposits which might interfere with breathing.—Mr. Rushton Parker considered that the hard material on the back did not appear to be situated in muscular tissue so much as in fascia. The material in the left thigh might be of the nature of myositis ossificans, while the small spike under the right side of the lower jaw had distinctly the feel of being situated in the muscle. It would appear that some general state of the system accounted for this curious disease and it was stated that the boy's mother was very rheumatic at the present time. If removed partially or wholly an opportunity would be given to examine its histological appearances.

Dr. Alexander read notes of a case of Pylorectomy for Stenosis of the Pylorus in which Murphy's Button was employed and the patient quickly recovered.—Mr. Rushton Parker said that cases such as that threw great light upon the question of ulcerated stomach. The cicatrices mentioned by Dr. Alexander and found by himself in a recent case of pyloroplasty for stenosis together with the long-continued dyspeptic symptoms seemed to suggest the cicatrisation of ulcers as a cause. In his case a small ulcer actually existed at the time of operation on the stomach side of the narrowed pylorus. In neither of the two cases operated on by himself was the mucous membrane of the narrowed part itself the seat of recognisable scarring which existed only in the neighbourhood.—Mr. F. T. Paul thought that the specimen shown was a congenital stricture. He would not dispute the wisdom of selecting pylorectomy in this case, but he might say that pyloroplasty had a much wider range in its suitability for long and narrow strictures than some were disposed to admit.

Dr. Briggs read a paper on Vaginal Section, mainly based on 16 operations in his practice. In 13 posterior vaginal section and in three anterior vaginal section was the operation performed. The cases treated by posterior vaginal section included five of hæmatocele due to ectopic pregnancy, three of tubo-ovarian cyst (ovarian hydrocele), one of simple papilloma of both ovaries, one of hydrosalpinx, one of chronic infective salpingo-oöphoritis, and two of chronic infective metro-salpingo-oöphoritis (with hysterectomy), 13 in all. Anterior vaginal section included three of chronic salpingo-oöphoritis with retroversion, for each of which after the removal of the ovary and tube the uterus was steadied forwards by vaginal fixation. In hæmatoceles the vaginal drain was employed in chronic cases and the important question seemed to be—Was it necessary to empty or remove the Fallopian tube in cases of incomplete tubal absorption or tubal mole? The uncertainty of being able to recognise the tubal condition ought not to be disregarded until it had been shown that drainage alone was sufficient. In three cases a portion of the outer end of the tube was removed and in two cases the tube was neither felt nor seen. All the cases, with one exception where the patient was lost sight of, recovered equally well. Operators seemed to agree that the tubes and ovaries might be left behind. Available evidence pointed towards posterior vaginal section as the treatment of chronic hæmatocele distending the pouch of Douglas. Tubo-ovarian cysts, simple papillomatous growths, and salpingo-oöphoritic lesions, if accessible from below, could be removed from the pouch of Douglas by posterior vaginal section. It was evident that where there were matting, thickening and firm fixation, especially towards the lateral walls of the pelvis, there was difficulty in securing the pedicle. More room was obtained by removing the uterus which in infective inflammations was often, as Landau had urged, in an incurable state. Dr. Briggs removed the uterus in two of the cases quoted because of the conditions alluded to. One patient lost her life from hæmorrhage 30 hours after operation; the hæmorrhage had been concealed behind the cyanide gauze pack. This case was a posterior vaginal section for adherent hydrosalpinx with thickened broad ligaments and an enlarged stiffened uterus. The specimen was carefully examined post mortem; the stump was apparently securely held by the silk ligatures still *in situ;* the end of the stump was swollen and its margins were recurved; the uterine artery was tested by injection and water oozed through the vessels of the stump, but a thicker pigmented starchy solution would barely pass. Shrinkage of the stump and difficulty in securing the proper constriction of thick rigid tissues rendered tense by forcible traction during operation explained the incomplete hæmostasis. The results in the cases of removal of the appendages with vaginal fixation for retroversion effected by anterior vaginal section were too recent to report upon. In the 16 cases there had been one death from hæmorrhage as reported.—Mr. BURTON had not himself opened Douglas's pouch for hæmatoceles, as all his cases during one year got better very well without, and he agreed with Dr. Briggs that they generally did if left alone; at the same time he was of opinion that by operation the patient's stay in hospital would often be shortened. He had opened the peritoneum per vaginam six times during the year for inflammatory tubal affections, removal of enlarged ovaries, and once for removal of a dermoid containing about 12 ounces of fat. There was less shock than by the abdominal route. By this operation a scar was avoided as was the danger of ventral hernia in the cicatrix.—Dr. E. T. DAVIES thought that vaginal section was only practicable in a minority of cases of pelvic disease—viz., small tumour formations and inflammatory products which encroached upon or were adherent to the pelvic floor, early ectopic pregnancies with recurrent or dripping hæmorrhages, or suppurations which became encapsuled in Douglas's pouch. These if they do not recover spontaneously by absorption, as many do, may be safely and easily opened and drained through the posterior fornix. The fulminating ectopic ruptures with copious hæmorrhage into the general peritoneal cavity with intense collapse should always be attacked from above by laparotomy. Pus tubes and ovarian abscesses with dense adhesions to the pelvic floor might more safely be opened from below. There could be no doubt, however, that the abdominal route by laparotomy offered far greater facilities for precision in diagnosis, dealing effectively with adhesions and stanching hæmorrhage, the whole field being so much better under the control of the operator than is possible by the vaginal route.—Dr. GEMMELL referred to the absence of shock after vaginal section due probably to the absence of physical irritation of the peritoneum from the cooling and handling of the intestines which was inevitable in abdominal section. He did not agree with the view that by the abdominal route a better inspection of the field of operation could be obtained, for by means of the anterior vaginal incision the uterus and appendages could be turned out for inspection and replaced with little or no irritation to the patient. Whilst convalescence was rapid there was greater freedom from pain and the vaginal incision cicatrised early, yet, just as in abdominal section, the wound did not always heal by first intention and hernia might occur.—Dr. GRIMSDALE considered that owing to the want of accurate diagnosis in pelvic disease the vaginal operation should be limited to the most simple cases. Slight errors in accurate diagnosis were more likely to assume grave proportions during vaginal operation than during abdominal operation. He did not suppose that anyone would contend that the actual opening of the peritoneum was safer in one place than in another. The case of the operation would therefore be in the long run the measure of the safety of any method.—Dr. BRIGGS replied.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Malignant Disease of the Œsophagus.—Exhibition of Specimens and Lantern Demonstration.

A PATHOLOGICAL meeting of this society was held on Feb. 17th, Mr. C. J. WRIGHT, Vice-President, being in the chair.

Dr. POWELL WHITE read a short communication on Malignant Disease of the Œsophagus and showed the following specimens:—1. Sarcoma of the Pharynx. The primary growth was a small ulcer in the right sinus pyriformis; it did not invade surrounding structures. The glands in the neck formed a mass half as large as the man's head. There were metastatic deposits in the liver, lungs, and heart. 2. Lymphosarcoma of the Mediastinum invading the Heart and the Œsophagus. 3. Cystic Kidneys in an Adult. The left kidney weighed 4 lb. 14 oz. and the right 2½ lb.; he thought that their origin was a congenital malformation. 4. Multiple Diverticula of the Small Intestine from the same patient as the cystic kidneys. There were about 30 diverticula situated along the mesenteric border of the small intestine; they were formed by protrusion of the mucous membrane through a deficiency in the muscular coat. 5. Spheroidal-celled Carcinoma of the Upper End of the Œsophagus with Metastatic Deposit in the Stomach.

Dr. BEDFORD PIERCE (York) showed:—1. Intracapsular Fracture of the Femur in a male, aged 64 years, the line of fracture being immediately below the articular surface of the head of the bone. In this case there was *no shortening until* some weeks after the injury. 2. Repair of Fracture of the Radius under most unfavourable circumstances, the patient being 84 years of age and maniacal, and no treatment was possible. Nevertheless, the bone had united well. 3. A Diverticulum of the Bladder the cause of which was obscure. The diverticulum was about half the size of the bladder and connected with it by an opening that would just admit a goose quill. 4. Brain of a Microcephalic Idiot of low type. Dr. Pierce pointed out that the posterior lobes were small relatively to the rest of the brain and that they failed to cover the cerebellum. He remarked that the brain when first removed weighed 38 oz. and that after being hardened in formalin for six weeks it had gained 10 oz. in weight.

Mr. GOUGH communicated a short paper in which were detailed the Microscopical Changes in the Lymphatic Glands, Spleen, Liver, and Lungs from a case of Hodgkin's disease. The paper was illustrated by microscopical preparations.

Dr. WEST SYMES (Halifax) showed a Dermoid Cyst of the Ovary containing fully-formed teeth, hair, skin, and bone from a patient, aged 39 years. At the operation the cyst was found to be very adherent to surrounding structures. The adherent vermiform appendix was removed with the tumour. The patient was discharged after an uninterrupted recovery.

Dr. CHURTON showed:—(1) A Thoracic Aneurysm which had pointed in the axilla; and (2) the Parts involved in a Subphrenic Abscess.

Dr. R. H. HALL showed a Perforated Gastric Ulcer from a young man, aged 22 years. The symptoms were indefinite and death rapidly took place.

Dr. EURICH (Bradford) showed:—(1) A Large Ulcer of the Stomach, death having been due to hæmorrhage; (2) a Primary Sarcoma of the Sternum; and (3) a Glioma of the Brain from a boy, aged five years.

Dr. HELLIER showed a specimen of Hæmorrhage into the Ovaries and a Skiagram of Congenital Deformity.

Dr. EDGERLEY (Menston) showed a specimen of Porencephaly in which the area involved extended from considerably in front of the position of the anterior limb of the Sylvian fissure, on the left side to the posterior parietal lobule and from the upper part of the second frontal convolution above to the inferior temporal sulcus. In this area the brain cortex was entirely absent and the white matter was represented only by a thin membrane separating the cystic space from the lateral ventricle on the inner side. The outer wall was formed by the pia arachnoid membrane. The optic thalamus was atrophied and the opposite half of the cerebellum was much reduced in size. The pyramidal tract on the same side was diminished in the crus, pons, and medulla. The patient from whom the brain was taken had died at the age of 43 years and had been a congenital hemiplegic imbecile who had suffered from epileptic fits for 15 years before her death. The area involved corresponded to the distribution of the middle cerebral artery—a fact supporting the theory of vascular occlusion as a probable cause.

Mr. LITTLEWOOD showed among other specimens:—(1) Tuberculosis of the Flexor Sublimis Tendon secondary to Disease of the Synovial Sheath; (2) a Pedunculated Subsynovial Lipoma removed from the knee-joint; and (3) Cysts of the Left Ovary and Half of the Right Ovary also containing Cysts removed from the same patient.

Dr. WARDROP GRIFFITH showed two specimens of Pneumonic Lung, one of which was associated with infective endocarditis; also specimens of Malformation of the Tricuspid Valve and of Abnormal Chorda Tendinea in the Left Ventricle.

Mr. MOYNIHAN showed among other specimens:—(1) Three Examples of Acute Perforating Appendicitis; (2) Intussusception in a dog; (3) Photographs and Watercolour Drawings from cases of Retro-peritoneal Hernia; and (4) (with Dr. GRIFFITH) Right and Left Duodenal Herniæ.

Mr. MOYNIHAN and Dr. POWELL WHITE showed a Tumour removed by operation from the Retro-peritoneal Tissues occupying the positions of the suprarenal body and kidney which were entirely absent; the mass also extended into the scrotum. Microscopically it consisted of myxomatous tissue containing fat and the remains of glandular epithelium.

Mr. WARD and Dr. POWELL WHITE showed a Retroperitoneal Tumour removed by operation. Microscopically it was a lympho-sarcoma.

Mr. WALTER THOMPSON showed an Epithelioma of the Upper Jaw arising from the nasal surface.

Dr. ALLAN showed among other specimens:—(1) The Intestines from a case of Typhoid Fever in a woman, aged 70 years; (2) Ulcerative Colitis apparently due to Influenza; and (3) a Collar-like Stricture in the Lower Part of the Œsophagus.

Dr. BRONNER (Bradford) showed numerous microscopic specimens demonstrating the Various Growths of the Nares—sarcoma, cylindroma, papilloma, myoma, adenoma, carcinoma, tuberculous growths, &c.; also specimens illustrating the degenerative and hypertrophic changes which take place in the mucous membrane of the nares.

Dr. TREVELYAN showed:—(1) Diphtheria Bacilli from a case of Membranous Stomatitis without involvement of the Fauces; and (2) True Hypertrophy of One Lung from a Case of Long-standing Quiescent Disease of the other Lung.

Dr. TREVELYAN and Mr. SECKER WALKER showed Sections through the Cerebrum and Cerebellum from a case of Suspected Intracranial Abscess. There was no abscess found, although during life the symptoms were so marked as to necessitate an exploratory operation. The specimen showed considerable hæmorrhage along the tracks of the exploring trocar. No gross lesion such as would account for death was found in the body. More than 40 microscopic preparations were shown illustrating the naked-eye specimens.

Professor BIRCH gave a lantern demonstration on the Commoner Blood Spectra produced by Drugs and Poisons.

New specimens recently added to the Anatomical and Pathological Museums were shown by Dr. GRIFFITH and Dr. TREVELYAN respectively.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Dislocations and Fractures of the Astragalus.—Excision of the Cæcum.

A MEETING of this section was held on Jan. 20th, Mr. R. L. SWAN, the President, being in the chair.

Mr. H. GRAY CROLY read a paper on Dislocations and Fractures of the Astragalus, giving a history of several cases. In one case fracture of the body of the astragalus was caused by a horse falling on a man's foot which was caught in the stirrup. Mr. Croly excised the bone and the man was enabled to resume his work as a groom. In a case of compound luxation of the astragalus forwards and outwards the bone was completely displaced from all its attachments; the head and neck of the bone protruded. Mr. Croly excised the astragalus. The accident was caused by the man jumping from a vehicle and alighting on his heel; the foot was forcibly inverted; the internal malleolus was completely buried; the patient made an excellent recovery and can walk as well as ever. The third case was one of complete simple luxation of the astragalus forwards and outwards. The patient, a man in his sixty-ninth year, slipped off the kerbstone into the channel, violently twisting his foot inwards. On examination by Mr. Croly 11 days afterwards the right foot was found to be forcibly inverted, the head and body of the astragalus resting on the dorsum of the foot externally; the skin over the head of the astragalus was red and shining; the internal malleolus was completely buried, a deep groove taking its place; there were two sloughs on the outer side of the foot (ashy grey) and a large deep slough on the inner side of the foot; there was no movement at the ankle; the patient's health was much impaired. About two months after the injury Mr. Croly excised the astragalus. Immediately on the enucleation of the bone the muscles drew the foot into its normal position and a suitable splint, with footboard, was applied. The patient made an excellent but somewhat slow recovery and he now can walk without the aid of a stick; an extra sole on his boot makes up for the slight shortening; he has an ankle moveable but perfectly firm.—Mr. LENTAIGNE exhibited a cast of Fracture of the Astragalus. This particular injury was exceedingly rare. It was a fracture of the anterior portion of the astragalus, with displacement forwards and outwards of the fractured head of the bone, and was caused by jumping off a car. After an interval operation was allowed. The loose head of the astragalus was found to be completely detached from all structures except by a few threads of fibrous tissue. The head of the astragalus was reduced and the wound was closed.—Mr. W. I. WHEELER mentioned a case of Dislocation of the Astragalus backwards the result of a blow by a cricket ball on the front of the foot when in the flexed position. He said that Mr. Henry Hancock's statistics of 109 cases of complete removal of the astragalus for compound dislocation, simple dislocation, and disease showed 14·6 per cent. death-rate.—The PRESIDENT said that he had often had occasion to remove the astragalus for aggravated equino-varus in the adult.

Mr. JOHN LENTAIGNE exhibited a patient from whom he had removed the Cæcum and a Small Portion of the Ileum for Chronic Intestinal Obstruction resulting from Stricture at the Junction of the Ileum and Cæcum. The patient, a girl, aged 12 years, had come under his care on April 16th, 1898. She was then in a very miserable condition, vomiting frequently and rejecting almost all food; the abdomen was greatly distended. The bowels were very constipated, no motion ever coming except after the administration of purgatives followed by enemata. The illness had commenced two years before. On April 22nd Mr. Lentaigne opened the abdomen in the median line and gave temporary relief by forming an intestinal fistula in two stages after first emptying the distended ileum by enterotomy. On incising the gut two large basinfuls of pea-soup-like fæces flowed out and the intestinal cavity was irrigated and washed out with a stream of warm water; the opening was then closed by silk sutures and the gut was returned to the abdominal cavity. When emptied and flattened out the intestine seemed to be about four inches across from the lower margin to the mesentery. The left hand of the operator was introduced into the cavity and directed well over to the left side; it was then cut down upon and the bowel was securely fastened to the opening by a few sutures passing through the parietal peritoneum, muscle and skin. The incision in the median line was closed with three layers of sutures, the two deeper of silk for peritoneum and muscle and the superficial of catgut for the skin, covered by a layer of celloidin. The small opening on the left side of the abdomen was kept open by a plug of iodoform gauze and on the third day after operation the fistula was made complete by an incision into the bowel. There was an immediate improvement in the patient's condition. The bowels emptied themselves continuously through the fistula and the vomiting and attacks of pain ceased almost at once. On June 27th, as the patient had got into a good condition and was anxious to be relieved of the annoyance of the fistulous opening, excision of the cæcum was performed with end-to-end suture of intestine by Kocher's method. The bowels acted naturally four times on June 29th and almost every day after. The intestinal fistula closed of itself as soon as the bowels acted normally and on July 12th it had practically closed, neither fæces nor flatus coming through it. It was now represented by a firm, clean scar, no trace of the opening existing. The patient was in excellent health and condition, the bowels acting regularly every day.—Mr. CROLY congratulated Mr. Lentaigne on the success of the operation which he said would not have been undertaken a few years ago.

NORWICH MEDICO-CHIRURGICAL SOCIETY.—Meetings of this society were held at the Norfolk and Norwich Hospital on Feb. 7th and 21st, the President, Mr. W. E. Wyllys, being in the chair.—A discussion took place on the Aims and Objects of the National Association for the Prevention of Consumption and other Forms of Tuberculosis.—Sir Peter Eade opened the discussion, speaking first on the necessity of educating the public and referring to the increased knowledge of tuberculosis. He mentioned some striking facts which would appeal to the public—e.g., that one-tenth of the population died from it and that phthisis kills in England alone from 40,000 to 60,000 annually. The Norwich mortality for 1897 was 2062, of which 238 were due to tuberculosis. Prevention included attention to expectoration, provision for healthy cows, and pure meat; but as many other sources of the disease might exist they must not be too sanguine as to at once stamping it out. Referring to the inspection of slaughter-houses Sir Peter Eade thought that more good would be derived from Government inspectors than from medical men.—Dr. S. J. Barton observed that the strongest argument against notification was that it would intimidate the earliest incipient cases from applying to their medical advisers at a time when there was the best chance of cure by the fear of being publicly branded as "consumptives." The two conclusions from all that had been written and spoken lately on the subject of tuberculosis were—(1) that the disease was infectious and spread by avoidable causes—viz., atomised sputum and milk, &c.; and (2) that when infected the open-air treatment gave the best chance of cure.—Dr. Burton-Fanning observed that there were already 20 branches of the association in process of formation and he sincerely hoped that the outcome of that meeting would be the starting of one in Norwich. He described the objects of the association as twofold: the education of the public as to the common channels of infection and the erection of sanatoria for those already attacked. The public must be enlightened as to the danger of consuming milk from tuberculous cows and should demand from dairymen a guarantee that the tuberculin test was used and acted on by them. They must also be warned of the infectivity of discharges from patients with tuberculosis and of the simple means of obviating that. He added that at more than one place the establishment of a sanatorium had been followed by a diminution in the number of consumptive natives. Owing to the precautions taken the risk of infection at a special institution for phthisis was reduced to a minimum.—Dr. Cooper Pattin, medical officer of health of Norwich, was of opinion that it was absurd to start upon a campaign against tuberculosis without informing themselves of the number and disposition of the sufferers from the disease, and this knowledge they could best acquire by notification. He therefore placed in the first rank notification of all tuberculous diseases with, as a necessary corollary, the establishment of hospitals for the segregation of the dangerous cases, in particular persons who could not have even a room set apart for their use in their own homes. Next he placed regular inspection of dairy cattle and the tuberculin test, though he warned members that in his judgment many exaggerated statements had been made about ridding the world of intestinal tuberculosis in children; they would lower that amount, he hoped, but they would not eradicate the disease. Milk in his opinion was often contaminated in the dwelling. So important did he think infection in the dwelling that for five years he had carried out systematic disinfection after the death or removal of a tuberculous patient wherever he could gain consent to do so. Dr. W. M. Crowfoot advised affiliation with the central association so as to obtain good speakers for a public meeting. He hoped that changes would be brought about in the management of dairies, but he feared that little help was to be obtained so far from the Government. There ought to be fully-equipped sanatoria for the poor.—Mr. S. H. Long observed that they did not all regard the infection in the same light. Being due to the tubercle bacillus, a facultative saprophyte, it was both of a direct and indirect nature; the former, he thought, played a minor part in the spread of the disease, whereas the latter mode of infection could never be entirely got rid of and hence the disease could never be stamped out.—Dr. Beverley thought that the milk ought to be thoroughly investigated.—The President thought the meeting must decide on some practical resolutions.—Dr. Burton-Fanning then moved: "That the members of the Norwich Medico-Chirurgical Society are in favour of the establishment of a branch of the National Association for the Prevention of Consumption and Other Forms of Tuberculosis for Norwich and District."—This was carried unanimously.—Mr. Haynes Robinson moved the next resolution: "That a committee be formed to carry out suggestions and to call a public meeting and that the following be nominated as members of the committee:—for the city: Dr. Barton, Dr. M. Beverley, Dr. Burton-Fanning, Dr. J. Fielding, Dr. Cooper Pattin, and Mr. Haynes Robinson; for the county: the President, Dr. Crowfoot, Mr. H. C. Dent, Dr. Reeve Manby, Dr. C. A. Owens, and Mr. H. Bournes Walker, with power to add to their number."—This was carried unanimously.

BRITISH ORTHOPÆDIC SOCIETY.—A meeting of this society was held at the City Orthopædic Hospital, Hatton-garden, on Feb. 17th.—Mr. Jackson Clarke showed a case of severe Talipes Calcaneo-valgus of congenital origin. He pointed out that there was no defect of the fibula. The child after birth showed a tendency to fold the legs on the front of the abdomen with the feet together. He suggested that this had been the position in utero and was the cause of the deformity. The patellæ were dislocated outwards. In this and other respects the child had much improved under treatment by manipulations and splints.—Mr. Muirhead Little showed two cases of Supposed Injury to the Shoulder at Birth. In both there was a history of difficult labour, one being instrumental and in the other there was difficulty in delivering the shoulders. In both there was marked inward rotation of the arm at or just below the shoulders and the movements of that joint were very limited, in one case so much so that paralysis was suspected, but electrical examination showed that it was not present. The head of the humerus felt unduly prominent behind and there was a distinct depression in the region of the neck as though the diaphysis were displaced forwards and inwards. He had diagnosed separation of the epiphysis with rotation of the lower fragment. Massage and manipulations had effected some improvement. He had skiagraphed the parts but at this early age (three and five years) ossification was not advanced enough for much to be shown.—Mr. Jackson Clarke thought the cases were subacromial dislocations.—Mr. John Poland said that he had seen the case referred to by Mr. Jackson Clarke. He thought Mr. Little's cases were cases of injury to the upper end of the humerus. He believed that in such cases occurring in labour there might be an altered condition of the bone due to syphilis.—Mr. William Thomas thought the finger in the axilla in delivering was responsible for such cases.—Mr. Keetley thought that paralysis could not be excluded in one of the cases at least.—Mr. Poland then showed specimens of Fractured Neck of the Femur with vicious union in a youth, aged 21 years, with symptoms like coxa vara. He had excised the head of the femur and the redundant callus that prevented movement.—Mr. Poland also showed a specimen obtained by Excision of Dislocation of the Shoulder with Separation of the Great Tuberosity. There was no broadening of the shoulder such as was described in text-books. The patient had now a useful arm.—Mr. Poland also showed the cast of a case of Hallux Varus coming on at the age of 12 years in a congenital club-foot. There was some wasting as if from paralysis. He was inclined to excise the joint but it had proved unnecessary. He also showed a case of Hallux Valgus from no apparent cause. He had excised the joint.—Mr. William Thomas showed a Wrench for the Treatment of Talipes. He did not think that wrenching alone would cure talipes, but whatever could be done by wrenching this instrument would enable them to do.—Mr. Chisholm Williams showed casts of cases of Webbed Fingers from Burns and of Great Progressive Hypertrophy of the First and Second Toes in a girl, aged four years, first noticed three weeks after birth.—Mr. Noble Smith thought that it was a case of diffuse lipoma.—Mr. Jackson Clarke thought that diffuse osteoma could not be excluded.—Mr. Poland agreed that it was probably diffuse lipoma but suspected that the bones were enlarged.—Mr. Muirhead Little recalled a somewhat similar case shown by Dr. Robert Jones in which all the tissues were hypertrophied.—Mr. Chisholm

Williams also showed the cast of a Hand with Webbed Fingers from a Burn which he had successfully treated.—Mr. Keetley showed a Patient and a Skiagraph. The case, he thought, was one of coxa vara. The patient was 19 years old, and had had very severe knock-knees straightened by another surgeon by means of instruments. She had only then been able to hobble by lifting the upper part of each instrument with her hands. She now wore no instruments and could not walk at all. He remarked on the peculiar open face of the patient which he thought he had noticed in another case of coxa vara.—The proceedings closed with a vote of thanks to the committee of the hospital.

SOCIETY OF ANÆSTHETISTS.—A meeting of this society was held on Feb. 17th, the President, Dr. Dudley Buxton, being in the chair.—Mr. McCardie read a paper upon the Method of Prolonging Anæsthesia under Nitrous Oxide Gas by the use of a Mouth Tube. Since seeing Mr. Coxon's plan of injecting warmed nitrous oxide into the back of the mouth by means of an oral injector he had experimented and found the following plan to answer well. The patient is anæsthetised in the usual way. The nose is then clamped and a central gag being used a curved mouth tube is introduced just within the mouth and a supply of gas is injected with each inspiration. The buccal cavity thus becomes a sort of reservoir of gas and an anæsthesia of several minutes' duration can be obtained.—The President remarked that the quantity of gas required was an obvious disadvantage. The clamping of the nostrils by lessening the patient's powers of expiration would tend to prolong anæsthesia under any circumstances.—Mr. E. Willett felt that the use of oxygen with nitrous oxide was superior to any method of giving that gas.—Mr. C. C. Braine pointed out that no method of giving gas and oxygen afforded a "working anæsthesia" of several minutes which was obtained by the use of the mouth-tube.—Dr. Flux described his method of obtaining anæsthesia by nitrous oxide by the "open method." He had found that by dropping the nitrous oxide from the tube into a towel arranged about the sides of the face and around the chin but leaving the face above the level of the nose quite free he obtained a sleep-like anæsthesia and avoided all the discomfort and dread of "taking gas." He now employed cup-shaped celluloid face-pieces open above and obtained excellent results. The period of induction was no longer than ordinary and when anæsthesia was obtained he could prolong it by occasionally injecting gas into the mouth. It was necessary to prevent the gas escaping below. The induction and recovery were like going to sleep and awakening from it.—Mr. Bellamy Gardner referred to experiments with closed inhalers which showed that high percentages of air prevented anæsthesia.—Mr. H. Baldwin and Mr. C. C. Braine spoke of their experience of Dr. Flux's method and both expressed their gratification at the results which they had witnessed.—After remarks from Mr. Willett, Mr. Tyrrell, and Mr. Low, Dr. Flux in replying said that the test of anæsthesia was the absence of sensation, the observation of lid and conjunctival reflex and the general sleep-like appearance of the patient.—Mr. Burns narrated four cases illustrating the value of the mixture of oxygen with nitrous oxide for patients, who were bad subjects for ether or chloroform during surgical operations. In the first case the patient whose finger was amputated was a man, aged 53 years, very fat, an alcoholic, and suffering from aortic disease with albuminuria and glycosuria, and from a cough. He took the anæsthetic well. In the next two cases the patients suffered from empyema and in the fourth the patient, a young man who was to have a Thiersch skin-grafting performed, took the anæsthetic well at first but became slightly cyanosed with cessation of respiration later and required artificial respiration. This case illustrated the advantage of being able to throw in plenty of oxygen as by Hewitt's more recent apparatus. His older pattern was used, but it afforded too little oxygen, and hence the asphyxia complication related.—Mr. Harvey Hilliard narrated a case in which a youth who although subject to being faint had never fainted, passed into syncope while taking nitrous oxide and oxygen. The syncope occurred at the moment of incision into a furunculus in the auditory meatus, and was, Mr. Hilliard believed, caused reflexly by irritation of a branch of the vagus. He also read notes of a case of a Fit of Spasmodic Asthma following the inhalation of nitrous oxide gas and air in an asthmatic subject.

MIDLAND MEDICAL SOCIETY.—A meeting of this society was held on Feb. 8th at the Medical Institute, Birmingham, the President, Dr. W. G. Lowe, being in the chair.—Mr. Jordan Lloyd showed the Pelvic Genitalia which had been removed post mortem from a woman, 36 years of age, who had died from acute general pulmonary tubercle. She had never menstruated but had always had fair health, although somewhat delicate in childhood. The cervix uteri was normal in structure and one inch and a quarter long. The body of the uterus was small, about one inch and a half long. Its cavity was obliterated and contained old cretaceous tuberculous deposit. Each Fallopian tube was blocked by a cretaceous nodule of the size of a pea within an inch of the fundus uteri. Up to the points of blockage the tubes were of normal thickness, but beyond this they were atrophied to about two millimetres in diameter. The fimbriæ of the right tube were open and those of the left were closed by old peritoneal adhesions. The ovaries were normal in size and structure and contained Graafian vesicles. Many of the mesenteric glands were full of ancient tubercle which had evidently been laid down many years before. The vagina was normal. The absence of menstruation was clearly due to the obliteration of the uterine cavity and the plugging of the Fallopian tubes as above described. There was no other tubercle in the abdominal or pelvic cavities.—Mr. Jordan Lloyd also showed a Left Kidney removed successfully by lumbar nephrectomy from a woman, aged 20 years, who had suffered since childhood from periodical attacks of lumbar pain with diminished urine and the appearance of a tumour in the lumbar region, the symptoms disappearing with polyuria and the disappearance of the tumour. It was intended to transplant the ureter by a new attachment to the renal pelvis, but at the time of the operation there were practical difficulties in the way of carrying out this procedure satisfactorily. The kidney was therefore removed. The stalk of the kidney was first clamped by Doyen's forceps and the vessels and ureters were tied separately. The forceps were then removed. The patient made an easy recovery.—Mr. Christopher Martin showed an improved form of Steriliser. It consisted of two chambers, the lower chamber being used for boiling instruments in soda solution, whilst the upper chamber was for steaming dressings, towels, gauze swabs, &c. The lower chamber was large enough to hold an ordinary pair of midwifery forceps. The steam was conducted from the lower to the upper chamber by a pipe which delivered it near the top of the latter. Near the floor of the upper chamber three small holes were made to permit the escape of steam. By this arrangement the current of steam in the upper chamber took place from above downwards. He had also had a strong brown canvas case made into which the upper chamber could be packed; it then formed a convenient and perfectly aseptic method of carrying instruments, dressings, swabs, &c., from the surgeon's house to the patient's.—Mr. Martin also showed an Acetylene Lamp for Surgical Operations. It was essentially an acetylene bicycle lamp to which a convenient handle had been applied and to which he had had fitted a reflector which could give either a horizontal or a vertical beam of light. The whole packed into a neat leather case. It gave a brilliant light, was inexpensive (compared with electrical lamps), and was very portable. Its only drawback was the somewhat objectionable smell which all acetylene lamps gave off. Both the steriliser and the acetylene lamp had been made for him by Mr. Ash, Edmund-street, Birmingham.—Mr. J. Furneaux Jordan read a paper on the Advantages and Disadvantages of Vaginal Cœliotomy.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at the Medical Institution, Liverpool, on Feb. 17th, Dr. Donald, the President, being in the chair.—Dr. S. Buckley read the notes of two cases of Fibroids Complicating Pregnancy in which abdominal section was performed. Case 1 was that of a patient, aged 28 years, pregnant three and a half months. The fundus uteri was pushed to the left by a firm rounded swelling reaching up to the umbilicus and was very tender to the touch. On opening the abdomen the mass was found to be a soft fibro-myoma springing from the right side of the uterus. It was not pedunculated and could only be removed by abdominal hysterectomy. As the symptoms were not urgent the abdomen was closed. The patient made a good recovery and five months later was delivered naturally of a full-term child. Case 2 was that of a patient, aged 28 years, five and a half months pregnant. A tumour of the size of a large cocoanut was found to be attached to the left side of the fundus. It was freely moveable, very hard, and had caused severe pain, the result of localised peritonitis. When the abdomen was opened a pedunculated myoma was found attached to the left cornu of the uterus and adherent to the omentum. The pedicle was transfixed and ligatured in the ordinary way and the tumour removed. The patient made an uneventful recovery and is now almost at full term.—Dr. Arnold Lea read the notes of a case of Sarcoma of the Ovary occurring in a girl aged 13 years. The tumour which had attained the size of a seventh month pregnancy had been noticed for four months and had grown rapidly. The tumour lay somewhat to the left side, was very soft and was moveable. Per rectum the uterus was felt to be small and separate from the tumour and a pedicle could be made out on the left side. There was no ascites. The patient had menstruated normally twice. Abdominal section was performed. The tumour was adherent to the great omentum which was removed along with it. The right ovary was normal and was not taken away. The patient made a good recovery from the operation. The tumour was a soft sarcoma, very vascular, and showing numerous hæmorrhages. Microscopic sections showed it to be of the round-celled variety. The prognosis of sarcoma of the ovary in young girls was very bad. Of 26 cases recorded as operated upon seven died as the result of the operation —i.e., 27 per cent. Recurrence within a short time was very frequent, most cases dying from secondary growth within a year of the operation.—Dr. W. K. Walls read a communication on the Treatment of Severe Accidental Hæmorrhage, generally concealed, based upon a personal experience of 38 cases and he discussed the treatment of their condition. He maintained that rupture of the membranes as generally advised was injudicious owing to the inertia of the uterus generally present in these cases. He upheld the value of the plug and dilator combined, as in de Ribes's bag. He suggested that after delivery of the child if the uterus remained inert and did not respond to ordinary stimuli vaginal hysterectomy might be justifiable, stating that many of the fatal cases of concealed accidental hæmorrhage were brought about by the intractable post-partum hæmorrhage so commonly experienced.—The discussion on this paper was adjourned till the next meeting.—Various specimens of uteri were shown by Dr. Walter, Dr. Briggs, Dr. Gemmell, and Dr. Grimsdale.

CHELSEA CLINICAL SOCIETY.—A meeting of this society was held on Feb. 21st, Mr. J. Foster Palmer, President, being in the chair.—Dr. Herschell read a paper on Atony and Dilatation of the Stomach. He pointed out that atony was an unrecognised cause of many functional gastric troubles and that it was far more important to know the muscular state of the stomach than to make exact analyses of its contents. He divided atony of the stomach into three degrees: (1) the stomach took longer than normal to empty itself, but there was no absolute retention of food débris; (2) there was occasional food retention; and (3) there was constant food retention. The last two groups caused dilatation. As to its causation he noted—abnormal relationship between food and the stomach, intrinsic weakness of the stomach walls, and anatomical conformation of the stomach. The symptoms of atony of the stomach he considered were due to (*a*) local conditions, (*b*) reflex, (*c*) malnutrition, (*d*) defective absorption of water, and (*e*) absorption of toxins. Dr. Herschell then discussed the methods of physical examination and illustrated the splashing sound and auscultatory percussion upon a phantom consisting of inflated rubber bags. He thought that the only certain sign of dilatation of the stomach was the finding of food residues before breakfast. He laid stress upon the necessity for a prolonged and serious course of treatment and exhibited Turck's gyromele and his own apparatus for applying medicated hot air and the alternating needle bath to the interior of the stomach. Dr. Herschell also discussed electricity (showing an intra-gastric electrode), massage, diet, and drugs.—The President, Dr. William Ewart, Mr. Vinrace, and Mr. Nitch-Smith took part in the discussion which followed and Dr. Herschell replied.—Mr. A. F. Penny read a paper on the Radical Cure of Hydrocele, the discussion of which was postponed until the next meeting.—Dr. William Ewart showed a case of Chronic Rheumatism characterised by intense pain and immobility treated successfully by ice massage.—Mr. Vinrace showed a pathological specimen of Perforation of the Stomach due to Gastric Ulcer.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—An ordinary meeting of this society was held at 20, Hanover-square, W., on Feb. 23rd, the President, Dr. Radcliffe Crocker, being in the chair.—The following cases were shown and discussed:—The President: (1) Acne Varioliformis in a man; and (2) Elephantiasis Græcorum in a woman—leprosy in its earliest stages in a healthy-looking young patient.—Dr. P. S. Abraham: Father and child with Tinea Tonsurans. Each had a small patch on the back of the scalp. A specimen of the fungus (probably large-spored) was shown under the microscope.—Dr. A. Eddowes: A man with Folliculitis Necrotica.—Mr. W. T. Freeman (for Dr. Stowers): A case of Lichen Spinulosus in a woman.—Mr. W. T. Freeman: (1) A case of Leuco-melanoderma in a woman; (2) a case of Senile Seborrhœic Warts in a woman; and (3) a doubtful case of Rodent Ulcer upon the forehead of a woman.—The President, Dr. Bowles, Dr. Abraham, Mr. Hope Grant, Dr. Eddowes, and others joined in the discussions.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—The ninth meeting of the session was held on Feb. 17th, when Dr. T. K. Dalziel showed a successful case of Laparotomy for Perforated Enteric Ulcer, the first of its kind in Glasgow.—Mr. R. H. Parry showed a case of Impacted Extra-capsular Fracture of the Femur treated by incision over the trochanter and replacement of the fragments in proper position. The patient was going about in seven weeks and there was no shortening left.—Dr. J. G. Connal showed a very large Nasal Polypus with Cystic Degeneration which had existed for at least 18 months without causing inconvenience.—Dr. Glen showed a specimen of a Heart with a Single Ventricle from a child who lived to the age of five months.—Dr. R. M. Buchanan showed a drawing of a Heart with a Single Ventricle and a Single Auricle.

Reviews and Notices of Books.

General Physiology, an Outline of the Science of Life. By MAX VERWORN, M.D., Ph.D., Extraordinary Professor of Physiology in the Medical Faculty of the University of Jena. Translated from the Second German Edition and edited by FREDERICK S. LEE, Ph.D., Adjunct Professor of Physiology in Columbia University. With 285 Illustrations. London: Macmillan and Co., Limited. 1899. Pp. 615. Price 15*s.*

THIS work is one of those that will bear reading twice and reading carefully. The reader must not expect to find any details in regard to the functions of the body—no text-book description, for example, of the organs of digestion or circulation or of the structure or functions of the organs of sense. It is strictly confined to the consideration of those broad and general principles and facts which are common to all animals alike and the subject is treated in an original and very interesting manner. We may add that the translation reflects great credit upon Dr. Lee, being smooth and intelligible throughout.

It is well that from time to time a general review of such a subject as physiology should be made by a competent man—that we should, as it were, take stock of our possessions and determine what rests on solid fact and what is still debateable ground. Physiology has connexions with many sciences and its advances stand in close relation with the progress made in many very different fields of research. Its development consequently proceeds irregularly; at one time it receives an impulse in a special direction owing to the extension of chemical knowledge; at another, new fields of research are opened out by the improvement in physical appliances, as in the superior construction of the microscope and in the graphic method of registration; whilst in yet another the application of the electric means of research supplies the means by which physiological knowledge becomes increasingly exact and precise. Experimental investigation, embryology, and comparative anatomy have all contributed to raise physiology to the high position it

Supplement to THE LANCET, March 4, 1899.

REPORT OF
The Lancet Special Commission
ON THE
WATER SUPPLY & DISPOSAL OF SEWAGE
IN
RURAL DISTRICTS

Being an Inquiry Supplementary to a Recent Commission on the Relative Efficiency and Cost of Plumbers' Work.

INTRODUCTION.

THE Report of THE LANCET Special Commission on the Relative Efficiency and Cost of Plumbers' Work, published in THE LANCET of July 4th, 1896 and subsequently reprinted in pamphlet form and extensively circulated,[1] met with such favourable acceptance that it has been deemed expedient to extend the inquiry.

Nature of Inquiry —The former Report dealt only with town houses, where it was assumed efficient systems of public water supply and drainage existed It is, however, only too evident that in rural districts where no such provision exists there are a very large number of houses more or less isolated which are most inadequately provided for in these respects, and indeed are surrounded by most insanitary conditions. It is with these that the present Report deals

The Extended Nature of the Inquiry renders it impossible to avoid taking into consideration questions that are only remotely related to the plumber, and one of the principal difficulties is to confine the discussion of these collateral subjects within reasonable limits It must therefore be borne in mind that the object in view is to give a general outline only of the leading points.

The Importance of the Subject —The great importance of an adequate provision of pure air and water and the influence which they exercise upon the physical and moral well being of a people are so well known that it would seem at first sight unnecessary to call further attention to the subject That this is unfortunately not the case the annual death rate from preventable diseases bears a melancholy testimony

Preventable Disease —The mass of avoidable misery and suffering borne by thousands through the neglect of sanitary laws should surely enlist the sympathy and assistance of all Among the preventable diseases which may be regarded as connected directly or indirectly with defective drainage or polluted water are enteric fever, cholera, diphtheria, and diarrhœa; of puerperal fever alone some four thousand deaths occur annually, and undoubtedly a certain proportion are attributable to insanitary associations. Minor ailments, such as sore throat, indigestion, headache, and a general depression of vital force, are of frequent occurrence and may often be ascribed to similar causes.

The Economic Aspect —At the monthly dinner of the Article Club held at the Hotel Cecil in March, 1898, an after-dinner discussion on the Price of National Health was introduced by Mr Wolf Defries, the chairman. Mr. Defries said that notwithstanding modern progress in sanitation and public health matters, among males in 1895 the six principal zymotic diseases accounted for nearly 8½ per cent of the total mortality of the country, while tuberculosis accounted for 11 per cent more. The minimum value of a life had been calculated by Dr. Farr at £159 per head for lives of all sexes and ages calculated on the basis of the average earnings of the agricultural labourer, from which the cost of his keep was deducted Adopting this figure Mr. Defries showed that the country had lost in a single year—1895—£17,000,000 through preventable disease.

Instances —The outbreak of cholera in the east of London in 1666 was properly considered by Dr Netten Radcliffe to have arisen from the consumption of water taken from the polluted Lee

The outbreak of enteric fever at Worthing in 1693 was traced to contamination of the water supply by leakage of fæcal matter from the drain passing through fissures in the chalk into the well, a conclusion which was supported by Dr Klein's bacterioscopic examination of the well water The necessity for a frequent and regular bacteriological examination of any public water supply, in preference to a merely chemical one, is well exemplified in this instance Upon this outbreak Dr. Theodore Thomson reported that several chemical analyses of Worthing water, taken before as well as after the date on which the new supply was utilised, failed to detect any definite impurity in the water It was also reported by Dr Dupré that previously to the outbreak Professor Crookshank made two bacteriological and three chemical examinations with negative results.

The outbreak of cholera at Hamburg was traced by Professor Koch to pollution of the water from an infected vessel in the harbour combined with a defect in a filter at the waterworks In fact, most of the epidemics within recent years of enteric fever, cholera, or diarrhœa have been traced to either the water supply or to defective drainage, the defects in the former being frequently caused by some defect in the latter.

Cholera at Altona —As an instance of the liability of defectively planned sanitary appliances to become a source of danger to life when surrounded by other than normal conditions, the outbreak of cholera in Altona in 1893 in a poor district named Ottensen may be given Some of the houses were supplied with water from a well having a wooden top covered with earth and stones. Owing to the frozen state of the ground and gullies some badly polluted refuse water escaped over the surface instead of entering the drain and percolated into the well. Other houses in the same district not using the water from this particular well escaped infection. In the previous summer, when Hamburg suffered so severely from cholera owing to the polluted water-supply, this district, with the exception of two cases (one known to have been imported), was free although using the well. The sanitary surroundings were in a very unsatisfactory state. The same lesson is taught by every fresh outbreak of disease, yet but little impression is made upon those in other districts where exactly similar insanitary conditions prevail.

---

[1] Copies of the Report in pamphlet form may be had on application to the Manager, THE LANCET Office, 423, Strand, W C, price 6d., or 7½d post free

Apathy of the Public arises from general indifference, a dislike to any alteration in the existing arrangements, coupled with an ever-present difficulty in all questions—viz., that of cost. No doubt of late years the depression in agriculture has formed an additional barrier to rural progress in these matters. To these causes may be added the fact that with most defective surroundings those in occupation frequently continue for a lengthened period without suffering any marked decline from a normal standard of health. The chance addition of some one untoward factor, a stopped drain diverting a flow of sewage or a severe frost fracturing the side of a reservoir, may be the immediate cause of an epidemic.

Local Waterworks.—It is, however, satisfactory to know that there are exceptions to this spirit of apathy, and there are in some places land-owners and others, members of parish councils or rural district councils, who are fully alive to the importance of these questions. It is such men, generally in the face of much opposition, who avail themselves of the powers conferred by the Acts of 1875, 1878, and 1894 to establish waterworks on a small scale for the supply of their own and their neighbours' houses in cases where the individual supplies are known to be defective.

Water Analysis.—Too much reliance must not be placed upon an analysis of any water intended for drinking, for water taken from the same source at different seasons may vary in a most remarkable manner. Dr. J. C. Thresh, medical officer of health of the Essex County Council, indeed, states that he has in two samples taken from one well at the same time, but at different depths, found very different results. Heavy rains materially influence water by washing various substances into the source from which it is taken.

In submitting a sample for analysis the vessel intended to hold it must in the first place be scrupulously clean and be fitted with a clean cork or, what is better, a glass stopper. It is well also to rinse it often with some of the water to be tested. After collection it should be submitted to the chemist with as little delay as possible. It is always impolitic, not to say unfair, to the analyst not to furnish him with the very fullest particulars of the source and its surroundings from which the sample is taken for this reason. An excessive amount of albuminoid ammonia or free ammonia might not condemn the water if their presence was known to be due to vegetable decay, though the same would be considered highly dangerous if the pollution arose from an animal source, though, of course, any excessive quantity must always be regarded with suspicion. Again, the absence of these substances is no conclusive proof of the safety of a water for dietetic purposes. Also the amount of chlorine in any sample, although it might indicate original organic pollution, need not of necessity condemn a water as the organic matter present originally might have become completely oxidised, the amount of chlorine remaining constant. It must, however, be remembered that local inspection of the source of supply is the only satisfactory method of estimating the risk of pollution to which such supply is liable.

Bacteria.—Again, should a bacteriological examination reveal any specific pathogenic organisms all doubt would at once be at an end, but when the search for them has been compared to that for the needle in the proverbial haystack their non-discovery is hardly conclusive proof of their absence. Professor Koch lays it down as a working axiom that any water that holds more than 100 bacteria germs capable of development to the cubic centimetre is unsafe for drinking. This seems to leave the odds rather in favour of the enemy, but when Professor Pfuhl speaks of having counted as many as 302,400 germs in one sample c.c. the 100 or less may be accepted in a spirit of thankfulness. There would seem good reason to believe that certain micro-organisms always present in fæcal matter may, under some conditions, assume a pathogenic character.

Dairy Farms.—A knowledge of the many opportunities for the pollution of a water-supply gathered from cases that have been reported upon from time to time makes it evident how much remains to be desired. Especially is this the case with regard to the water-supply of dairy farms, which requires careful supervision. As an illustration of want of observation on the part of an inspector and the little reliance to be placed upon water analysis the following is given. A man, thirty-six years of age, was taken suddenly with gastroenteritis; being placed upon a milk diet the symptoms rapidly became aggravated. The milk food was stopped and barley-water alone was given for forty-eight hours with marked improvement, only to be followed by a relapse on a return to milk food. The milk was again suspended with relief to the patient, but still it was not suspected, as others in the house were taking it in tea without ill effect; but when the milk was tried by the patient for the third time the connexion with the symptoms became too apparent. A change in the source of the milk-supply at once moderated the attack and a rapid and uninterrupted recovery was made. An examination of the premises from which the original milk was obtained revealed a shallow well in close proximity to a graveyard with a loam and gravel soil. The water from this well had been used for washing the milk cans. These premises had frequently been examined by the local sanitary inspector and presumably the nearness of the well to the graveyard had never occurred to him, though, as a matter of fact, they were only divided by a high wall. A few months prior to this occurrence an analysis had been made of the water with satisfactory results, but a second examination showed it to be highly contaminated. The first was made after dry weather and the second after wet. Several other cases of illness occurred in patients using milk supplied from this farm and the well was closed.

The Country Plumber.—The plumber is to a very large extent the master of the situation. This reflection possibly is not calculated to afford much consolation, more especially to those who are familiar with him in what may be termed the wild state. His opportunities for improvement have been limited, while frequently the little technical knowledge which he possesses impresses him with his own notions and bars his further progress. There are, of course, many exceptions, but the good man is as a rule drawn to the towns. When his powers for evil are contemplated a more than usual interest in his proceedings is engendered. What matters the original purity of water in a well if the plumber fixes the suction-pipe in such a manner as to allow foul surface water to flow back round the outside of the pipe into the well and pollute it? It is therefore of the greatest importance that the plumber should receive every encouragement for his improvement, as without doubt he occupies a most responsible position.

Should any considerable sanitary alterations be contemplated on a property doubtless an architect or other competent person would be consulted. In the majority of minor cases it is the local jobber, possibly a blacksmith or carpenter by trade, who makes what he considers the necessary alterations. Under these circumstances the desirability of keeping the water-supply and the sanitary arrangements as distinct as possible must be apparent to all. The plumber is, however, the man to whom attention must first be directed. Thousands of them, more or less competent, are at work in country places at the present time and it is no exaggeration to say that the result of their labours means health or sickness, life or death, to a vast number. The great difficulty is how these men are to be reached.

Plumbers' Registration, so as to ensure some measure of competency and control, offers the readiest means of grappling with the question. The Bill recently introduced into Parliament is most certainly deserving of more consideration than has hitherto been bestowed upon it.

Medical Officers of Health.—In the previous report it was suggested that the public were being educated to a right appreciation of this subject by the medical profession. Medical officers of health must still be considered our sheet-anchor and to them the public must look for any improvement and should yield them loyal support. There are many districts which active medical officers have made centres of light and learning in these matters and where their efforts have wonderfully reduced the local death-rate. It is desirable that these officers should wherever possible be free from the trammels of private practice.

Combined Drainage.—The law relating to easements is also one of great difficulty and at times a source of danger to the public health in growing districts. One cesspool is frequently shared by two or more properties and where alterations or additions are made to these buildings most undesirable complications not infrequently arise.

A common case is where the owner of a plot of land builds a row of cottages and drains them all into one cesspool in the garden of the end house. These houses in time are sold or let on leases with the usual covenants, including one for easement.

The lessee of the end house in this case has to keep his cesspool emptied to allow the contents of his neighbours' drains to escape. When a system of public sewers is introduced the lessee cannot connect his house into the new sewer and remove the cesspool until he has first drained into the sewer each of the houses connected with his cesspool. The result is that all these connexions with the public sewer are delayed, the unfortunate lessee paying the sewer-rate for each of these houses while retaining the cesspool and postponing, perhaps, the considerable outlay required from him.

Sanitary Inspectors.—One of the principal obstacles to progress in country districts is the insufficient emolument frequently offered to candidates for these most responsible posts. The poor remuneration, combined with the multifarious and often incongruous duties they are at times expected to perform, forms a barrier to commanding the services of the most able men.

District Councillors.—Speculating builders are frequently members of vestries and parish councils. They naturally seek to have a voice upon questions affecting new roads, rates, and many other matters in which they are more personally interested than most of their fellow parishioners; their influence, however, is not always for the general welfare where sanitary questions are concerned. The position of a conscientious sanitary inspector is often one of great delicacy in connexion with property held or erected by these members, the servant finding it difficult to take action against one of his masters. There are, however, cases where the presence of a builder upon a district council or vestry is a distinct gain. The individual interests of those in authority, in small districts in particular, greatly retards any advance towards a state of sanitary efficiency. A covers his garden with stables or keeps pigs; B runs the drainage from a row of houses into one cesspool in the end house in order that he may squeeze in an extra house in place of having them semi-detached, and it will be hard if C and D cannot find some way of making themselves a nuisance to their neighbours also. The result of this is that redress is most difficult to obtain. The sanitary inspector, generally a native, follows the lead of those who should set a better example. A, B, C, &c., are afraid of each other and look over these shortcomings by mutual agreement, well understood if not expressed. Here, again, the only hope rests with the medical officer of health.

Sewage Disposal: Water-carriage.—The water-carriage system has drawbacks and grave defaults are alleged against it, but it is the readiest if not the only method for the removal of excrement under the conditions of urban life. In the matter of sewage treatment we may expect to learn much from the Royal Commission now sitting on the subject.

Judging from present knowledge it is from some form of biological filter that deliverance from the difficulties connected with sewage disposal is to be expected. It is to a more natural system that attention is now being directed, for the use of chemicals is at best but an attempt to arrest a natural process, and by so doing the assistance of those forces of nature so beneficent as allies is lost, while an effluent is obtained unsuited for purposes of irrigation.

The Dry System.—If conformity with natural laws and the practices of antiquity are accepted as guides, then without doubt where circumstances permit the dry earth system is one that deserves most careful consideration. The great difficulty to be contended with in all systems of sewage disposal is the utterly listless, almost criminal neglect shown in regard to all matters of this nature by the bulk of the population. Any attempt at a general application of dry earth-closets most frequently results in disappointment, owing, firstly, to an erroneous impression on the part of local authorities that they will receive adequate attention from the individuals who use them; and, secondly, to the want of a scientific application of the dry methods where such have been adopted by sanitary authorities. At present the land to which the excreta are carried is usually too far from the points of collection. The large pails, intended to hold a week's output from each closet, are unwieldy, weighing when full some 180 lb. Their size renders them insanitary and repulsive, while their removal is both laborious and expensive. The amount of land frequently devoted to the purpose of reception is needlessly large. Recent experiments have proved that a plot of land of 600 square yards, equal to about one eighth of an acre, is sufficient for the disposal of the excreta of 100 persons per annum. The more central and the nearer the vicinity of the plot to the houses the less will be the expense of removal and the better the results obtained. By the adoption of some form of dry catch, such as described (pars. *144* and *209*), in place of the pail and by a system of daily collection one man with a hand truck would be capable of more efficient work than two men with a horse and trolley as at present. With the dry catch much of the liquid portion is evaporated, and the remainder being absorbed by the earth the contents of the catch cease to be sloppy, the weight being materially decreased. The almost universal but absurd custom of burying night soil deeply entirely defeats the object in view—viz., its rapid conversion into mould, whilst the practice adds greatly to the risk of polluting the surrounding water supplies. Night-soil so treated will be found at the end of many months still in its original foul condition. All such burial must be quite superficial—in fact, merely covered with earth. When this is done it will at the end of three or four days be scarcely—if at all—distinguishable from the surrounding earth. As a manure it may be said that fresh human excreta is unparalleled. Prejudice and the inherent slowness of the pastoral mind to assimilate ideas other than those acquired in early youth will probably contribute to the long-continued use of the inevitable leaky drain and cesspool. Indeed, it were vain to expect otherwise. The adoption of a well planned system of dry disposal by one of our large rural military depôts where such could have a fair trial might not only form a valuable object lesson to the country, but would afford excellent training to the troops in the event of active service in the field.

In place of any outlay upon main drainage and sewerage works necessitating the acquisition of considerable tracts of land for sewage farms, which last are not infrequently inadequately administered, an organised system for the daily supply of earth and for the removal and disposal of the contents of a suitable form of earth-closet would often be found more economical and sanitary. Notwithstanding the evils of the open cesspool system, with its many possibilities of water pollution, it is open to question whether the universal application of a regular drainage system in rural districts—always bearing in mind defective drains and fittings, *the vagaries of the so called plumber*, and the popular belief that a water-closet is a suitable receptacle for any odd refuse—may not at times be attended with equally injurious results.

Water supply.—An efficient system of drainage and the adoption of more natural methods for the disposal of sewage than commonly prevails is the first step to command a supply of pure water. In selecting a source for a water-supply ordinary common sense on the spot, when used, is mostly to be preferred to scientific knowledge at a distance. The wish to shift a responsibility on to other than our own shoulders and the glamour attached to any special knowledge in which we do not participate often induces us to think otherwise. The inquiry tends to show that, in most cases where there is no public supply and in some cases where there is, tube wells are the most wholesome and readiest source for a supply, though these are not wholly free from risk, yet when the tube passes through an impermeable strata the risk is reduced to a minimum. Rivers and lowland streams are, on the other hand, the most objectionable as being most liable to contamination and such water should never be used unless most efficiently filtered. In cases, however, as in the supply of large towns, much more care should be exercised than generally prevails to prevent fouling above the intake. Pending a development of the question of the London water-supply an infinitely purer water might be secured for London and other riverside towns if the Conservators of the *Thames* and the Lee were in a better position, both legally and financially, to detect and control the pollution of the rivers under their charge.

Old Country Houses are frequently worthy monuments of the artistic skill of the architects and the integrity of the builders of past generations. It would be little to the credit of their descendants if, fired by a new-born zeal, they disfigured their buildings with forests of unsightly ventilating pipes. Where difficulties in this respect present themselves the opinion of an architect should always be sought.

Plan of the Report.—A somewhat different system has been adopted from that of the previous report, it being found impossible to include all the necessary illustrations under a few examples. The subject is discussed under heads and the several sources of water-supply and the causes of possible pollution are taken in detail. To this is added a description of the means usually adopted for the disposal of the sewage.

One example only is given of a country mansion, but this is made to embrace a farmhouse and one or two cottages; the difference in treatment here is rather in degree than in kind. The question of efficiency has alone been dealt with, it having been found undesirable to offer any nearer approximation of prices than those already published for the town houses. This is owing to the fluctuations in the cost of labour and materials in different localities, the varying distances from towns or railways affecting the cost of cartage, &c. This may be roughly calculated at 10 per cent. advance upon London prices.

Results of the Inquiry.—The practical lessons to be drawn from the inquiry are briefly these: 1. To educate and register those employed as plumbers. 2. To bestow upon medical officers of health and borough surveyors a larger measure of independent authority than they at present possess, the interference by members of parish councils or vestries in purely technical questions being frequently attended with disastrous results. 3. The higher remuneration of rural sanitary inspectors with a view to attract more able men for the position. The same may frequently be said of borough surveyors. 4. The use of some simple form of biological filter, or the adoption of the best system of sewage treatment in all cases where the water carriage system is in use. 5. The great advantages possessed by the dry system for small or medium-sized properties for the disposal of excreta, the use of water carriage in these cases being at present almost invariably associated with cesspools and tending to soil and water pollution. 6. Additional care in the selection of water-supplies and greater regard for their protection from pollution together with provision for frequent inspection. 7. The little reliance to be placed upon any one analysis of water as conclusive evidence of its suitability for dietetic purposes and the great importance of local inspection in all cases.

THE REPORT.

1. In an investigation into a subject which, though mainly confined to plumbers' work, must of necessity touch upon most matters that relate to the sanitary condition of country houses, the difficulty of deciding what shall or shall not be included is great. The position of a house, the nature of the soil, its vicinity to water and trees may seem at first sight somewhat remote, but they influence considerably questions of water-supply, damp, and drainage. The internal plumbers' work in principle will be the same as described for town houses, but varied to meet the requirements of each case.

2. In a country house all drains connected in any way with a soil drain must be kept outside the building.

3. Water-supply will first be dealt with as briefly as possible. That this should be abundant and good in quality is one of the first essentials.

The desirability of various sources of water for domestic use are generally classed somewhat in the following order of merit:—

(1) Upland surface water after settlement in a lake or reservoir, as this water is generally impregnated with earthy matter.

(2) Deep well water from the chalk or greensand.

(3) Rain water collected on a properly prepared and enclosed ground.

(4) Land springs.

(5) Rain water collected from roof.

(6) River water.

(7) Shallow well water.

(8) Surface water from cultivated ground.

Nos. (5), (6), and (8) may be considered as extremely dangerous for dietetic purposes without previous treatment. No. (7) can only be used with safety where proper provision is made to exclude all surface or contaminated water.

4. The table given in the following paragraph on water-supplies and mortality from fever would at first glance seem to modify the above statement, but it must be remembered that the high place taken by river water as represented by London is owing to the very efficient system of filtration to which it is subjected and also to the sanitary surroundings of a large proportion of the people. Upland and moorland supplies are, on the other hand, very low down in the scale, owing in a very large measure to the defective sanitary condition of certain of the poorer districts.

5. *Water-supplies and Mortality from Fever.*—Mr. A. H. Smee, M.R.C.S. Eng., F.S.S., Chief Medical Adviser to the Gresham Life Office, in writing to THE LANCET, March 13th, 1897, gives the following. The table is the result of his investigations into the variations of the death-rate from enteric fever in several towns drawing their water-supplies from different natural sources. The calculations relate to the year 1896 and are taken from official Government statistics. The whole is of such interest that it is given *in extenso*. He says:—

"For comparison and to avoid decimals I have computed the mortality from fever per 1,000,000 living from a few typical towns the water-supplies of which are drawn from widely different sources.

	Rivers and Chalk.		
London...	137	Paris	110

Antwerp (river water treated by iron filtration and shallow wells)...	154	Bristol (red sandstone)	79
		Dorking (greensand; mean of last ten years)	70

It will be observed that towns drawing their water-supply from sands, melted snow, and rivers have a lower rate of mortality from fever than those drawing their supply from either chalk, peat, or moorland gathering ground.

"Dr. Seaton, the county medical officer of Surrey, has shown in his report on water-supplies that the mean death-rate from enteric fever for the last decade for Epsom and Sutton, which obtain their water-supply exclusively from the chalk, was at the rate of 190 per 1,000,000 living, and that this rate was an increase over the mean death-rate of the previous decade. The mortality from fever at Reigate, another chalk supply, was 160. On the other hand, Dorking, which formerly derived its water from the chalk, but now obtains its water from greensand, had a mean death-rate of 70 per 1,000,000, and shows a material diminution in the death-rate from this cause. In Chertsey, which derives its supply principally from the Thames, the mean death-rate from typhoid fever was 90 per 1,000,000 during the same period. ...... I trust that I have made out a *primâ-facie* case for an exhaustive Government inquiry as to the cause of the susceptibility to and immunity from fever amongst populations deriving their water-supply from various sources. Moreover, it is at least open to discussion whether municipal bodies, who are empowered to levy rates for sanitary administration, are suitable authorities to act as amateur managers of trading monopolies."

6. Before dealing with each of these various sources of supply in detail an enumeration of some of the principal causes of pollution to which they are liable may, in order that they may be guarded against, be briefly summarised under two heads:—

(1) Pollution prior to delivery into the house of the consumer.

(2) Contamination on the *premises.*

7. POLLUTION PRIOR TO DELIVERY INTO THE HOUSE OF THE CONSUMER.

(1) From sheep and cattle pastured on the gathering-ground or having access to the spring head or reservoir.

(2) Dead animals in such situations.

(3) Dogs entering reservoir.

(4) The solvent action of the water on the pipes used to convey same to house (see par. 43).

Note A.—Water charged with peat has an exceptionally rapid action upon lead owing to acidity produced by the action of certain bacteria in the earth through which it passes It requires special provision in filtering through limestone before passing into lead pipes.

(5) The tow used in caulking the joints of iron mains (see par. 41).

(6) The house refuse of any outlying cottage on the banks of some tributary stream.

(7) Through the leakage of surface-water into the storage reservoir, either over the top or through the sides.

(8) Or by the insuction of foul water into the supply-pipe from some defective drain, cesspool, or from the surface drainage of the land.

(9) By the percolation of sea-water into wells, particularly in times of drought owing to the lowering of the water in the well below the sea-level, as recently occurred at Eastbourne.

(10) Small animals often fall into wells open at the top, together with dirt and surface drainage.

(11) Subsoil water enters shallow wells through the sides from adjacent drains, graveyards, manure heaps, cesspools, middens, *especially in a porous soil.*

(12) Through rat-runs between wells and drains, admitting foul air or overflow water.

(13) By men employed in digging wells, or in enlarging the bottoms of existing wells, or in fixing deep well-pumps.

(14) Foul water frequently enters wells following the course of the suction pipe.

(15) Rotting wood used in the construction of wells encourages wood lice, &c., and fungus.

(16) Surface drainage is carried into springs and wells through fissures without having first filtered through the soil. In limestone districts water will travel in such fissures for long distances.

(17) Through the brickwork and new cement used in forming reservoirs, particularly if road drift is used in place of sand.

(18) By leaky gas mains.

(19) In rivers and streams—manure from cultivated lands is washed in by rain.

(20) Many drains discharge sewage and factory waste into ditches that feed the streams.

(21) The refuse of houseboats and barges often thrown into rivers.

(22) By dead bodies of men and animals.

(23) By decaying wood and vegetable matter.

(24) By men, cattle, and dogs bathing

(25) By gipsies and others camping out and washing clothes and foul linen in river.

(26) By dead birds and dead fish and refuse of picnic parties.

Most of the foregoing will be greatly aggravated in times of flood.

8. CONTAMINATION ON THE PREMISES.

(1) Cisterns without covers not only admit dirt, but mice, birds, and the remains of household pets are occasionally found in them.

(2) Ventilating pipes frequently terminate close to cisterns or their overflows or under the open eaves of the roof where cisterns are fixed.

(3) Air pipes from service boxes in cisterns supplying both closets and sinks.

(4) By waste pipes directly connected with soil drains.

(5) By broken cistern lids and felt used as a protection against frost falling into cistern.

(6) Service pipes laid in same trench with drain offer risk of insuction of foul water.

(7) By service pipes crossing under or over drains, unless especially protected.

(8) Rain water collected from a roof is liable to extra risks from soot, tame pigeons and wild birds large and small, their nests, also cats.

(9) Dead leaves and accumulation of dirt in gutters, particularly in trough gutters running from back to front inside roof.

(10) The dirty and indolent sometimes throw bedroom slops and rubbish into gutters from attic windows.

(11) Gutters are fouled at times by sweeps and other workmen.

(12) Neglected filters.

(13) Dirty sinks, especially housemaids' slop sinks, the taps of which are liable to be splashed by slop water, or have dirty house-flannels laid on them to drain often just prior to filling the drinking-water bottles

(14) From insuction where there is an intermittent supply.

Note B—Plumbers frequently fix in cisterns that are near sleeping-rooms a pipe on to the end of the ball valve to carry water to bottom of cistern without noise. When water is drawn from the main at a lower level this pipe acts as a syphon and will such back the water into main from cistern, including of course any dirt that may be in the cistern at the time. Very serious cases of insuction have been recorded, including one from a public urinal.

Labourers are commonly deputed to clean out cisterns, their boots and clothes are frequently defiled by working in old drains and in removing old soil pipes

(15) Water becomes polluted in cisterns placed in or over water-closets, also under floors of bedrooms and in sculleries and other places to which drain air may find access.

(16) *Underground* cisterns may be contaminated by defective drains and surface-water and are liable to damage by frost.

(17) From dipping dirty bowls, &c., into cisterns and storage tanks.

(18) From the action of water upon metals, as lead, galvanised iron, or zinc, used for cisterns or pipes, lead flats, or gutters.

(19) Through the use of dirty mops or brooms in cleaning out cisterns.

SOURCES OF SUPPLY.

9 *Moorland or Upland Surface Water.*—In order of initial purity we have "upland surface water." This generally forms the source of supply in mountainous or moorland districts, where the rocks are either igneous, metamorphic, or are formed of hard millstone grit. The thin soil does not admit of cultivation, and is used only for the pasturage of sheep. The organic pollution from this source may be reckoned almost *nil,* for, unlike the lowlands, where so many sheep are allotted to each acre, here so many acres are allotted to each sheep Occasionally one may die and decay in some out of the-way spot, or even fall off a rock and be drowned in a torrent bed. Even this is not such an important matter as might at first sight appear, for water that falls over rough and broken ground is very rapidly oxidised.

10. The town of Torquay, which draws its supplies from Dartmoor, has recently spent a considerable sum of money in obtaining the right to, and in enclosing, the watershed from which its supply is derived. It frequently happens that water drawn from such a source is heavily charged with peat or earthy matter and occasionally with iron, in these cases a subsidence reservoir is desirable. As already mentioned, water charged with peat acquires a considerable amount of acidity, which acts very rapidly upon metals, particularly upon lead, this action may be obviated by saturating it with carbonate of lime, which is done by passing it through a limestone filter, the only objection to this being that it adds considerably to its hardness. The experience gained from Yorkshire and other places using moorland water, should exclude the use of lead pipes (par. 43). Water containing carbonates forms a coating of carbonate of lead inside the lead pipe, which being insoluble in water prevents any further action taking place. Of course, being dependent upon such a source for a supply a reservoir is a necessity (*see* pars. 53 to 62).

11. The following is a digest of a short table recently

published by the Meteorological Office of rainfall during the past twenty-five years:—

Approximate Average Annual Rainfall.

England and Wales.	
North-east	26·50 in.
East	25·00 ,,
Midlands	25·00 ,,
South	29·00 ,,
South-west	40·40 ,,
North-west	36·60 ,,
Ireland.	
North	38·00 in.
South	39·00 ,,
Scotland.	
North	52·00 in.
East	32·00 ,,
West	50·00 ,,

12. It will be noticed that the annual rainfall varies considerably in different parts, but is usually heavy in the western counties and in elevated situations. The best way to form a calculation is to take an average of the fall in any three consecutive dry years, which will very likely amount to some 30 in. The general average would be much more, but this will probably be carried over the reservoirs in times of excessive floods. The quantity collected will prove to be considerably less than the rainfall, as it is affected by the nature and inclination of the rocks, the amount of vegetation, and the evaporation. Evidence has been given before a Royal Commission which would tend to show that this is a very constant amount and not dependent upon the rainfall, the average being about 13 in. The amount lost by evaporation from an open reservoir is about 30 in. in depth per annum over the whole surface.

13. *Deep Wells.*—Deeply dug wells are perhaps the next most frequent sources of supply. They are of course subject to the same risks of pollution as the shallow ones, with the addition of the possible entrance of contaminated water through fissures at a considerable depth. The outbreak of typhoid fever at Worthing in 1894 was from this cause, while the fact that fissures were present in the well supplying Eastbourne in 1896 is proved by sea-water having entered the well. This was in all probability owing to the drought in the early summer having caused the water in the well to sink below the sea-level. It is impossible to exercise too much care to ascertain the exact character of water entering wells through a fissure, especially if situated in the neighbourhood of thickly populated districts, as water has been known to travel long distances through them without undergoing filtration; indeed many wells have had to be abandoned on this account. The subject of the geological formations which are most desirable as sources from which to draw a domestic water-supply and the character and quantity of water likely to be found in the various strata, though interesting and intimately connected with the subject, can be omitted, the opinion of an expert upon these matters being invariably taken prior to the appearance of the plumber on the scene.

14. The practice of boring at the bottom of a dug well in order to form a reservoir, as well as to obtain a position for the pumps, is now seldom resorted to. With the dug well, unless the upper stratum be an impermeable clay, iron cylinders must be sunk as far as is necessary to keep out the surface drainage, as in shallow wells, and this is frequently a costly process. In the "Tube Well System" the tube from the pump to the spring is a continuous one, and the pump itself is attached to the tube by an air-tight connexion. This removes the pressure of the air from the water in the tube. The velocity of the flow of the spring is also thereby greatly increased, the removal of the pressure of the air from the water in the tube being equivalent to a greatly increased head of water in the spring. If necessary, these pumps can be placed as low as 150 ft. or 200 ft. from the surface. There is one point which should always be kept in view—viz., that the tube throughout must be connected so that neither surface water nor sand may obtain access into it. The cost of boring such a well to the depth of from 200 ft. to 300 ft. would amount approximately to some 20*s.* per foot.

15. The publicity given by inquests held upon workmen who have lost their lives by descending wells in which carbonic acid gas has accumulated should deter others from running such unnecessary risks, but apparently such warnings are thrown away. In The Lancet, Jan. 9th, 1897, an account is given of such a catastrophe in a well belonging to the Hastings Corporation which resulted in loss of life to one workman and nearly proved fatal to a second. The well was an open one some 60 ft. deep, lined with iron cylinders for 20 ft. down and with brickwork for the remaining 40 ft.

16. The common precaution of lowering a lighted candle into the well before descending had been neglected. It may be pointed out that it is only safe to enter a well when the flame of the candle burns with undiminished brilliancy and not only when it is not extinguished, as combustion may continue in air dangerously charged with carbonic acid. A well may be cleared of foul air by slowly lowering a bright fire in a perforated iron pail, when the heated air ascending carries up with it the heavy gas that has accumulated at the bottom, or a pail of freshly burnt lime saturated with water may be lowered, in which case the carbonic acid is absorbed.

17. In all cases where the supply is taken from a well pumps are necessary to raise and force the water into a reservoir or cisterns. The suction pipe should always receive particular attention, not only that surface water may not flow back round the outside of it into the well, but that the pipe is so supported and protected from injury in its course under the ground that no insuction of ground water may occur, such faults being very difficult of detection when they arise.

18. *Rain Water Collected from Artificially Prepared and Enclosed Ground.*—Rain water collected upon an artificially-constructed gathering ground is rather an expensive but a very satisfactory source of supply. Asphalt laid upon a concrete bed forms the best floor, the space necessary to devote to this purpose will of course be governed by the requirements of the establishment and the probable rainfall (see pars. 12 and 185). It is usually calculated from the fact that an inch rainfall yields some 22,622 gallons to the acre. It is most important that any artificial ground of this kind should be carefully fenced off, the lower part wired with netting sunk 2 ft. below the soil where it is turned outwards about 12 in. to exclude rabbits, and means must be adopted either by keeping the ground raised above the surrounding land or by forming a ditch round the same area to prevent the access of surface water.

Note C.—Rabbits in burrowing under any obstacle invariably sink a hole almost close to it and so come upon the buried wire; were it not that they were stopped by the horizontal piece forming a floor they would simply go down and under the vertical wire, but they seem to have no idea of working backwards so as to clear the 12 in. of flat wire.

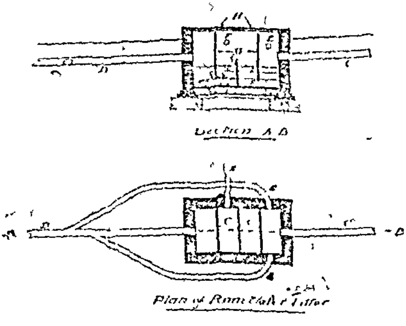
19. *Land Springs.*—Where a house is so fortunately situated as to have a constant and reliable spring in its vicinity the water can be conducted to it by gravitation if the spring is at a sufficiently high level (see par. 56). If, however, the house is higher than the spring, then it must be pumped up by means of a water-ram, a water-wheel, or a windmill (see pars. 46–49). Care should be taken to see that the spring is not fouled by cattle and small animals, or by drainage of surface water from the adjacent land. It should be railed round at least some 6 ft. from the edge, and the ground must slope away from and not towards it, as is more often the case, also as much as possible overhanging branches should be cleared from the trees that leaves may not fall into it. Should the spring be steady but small in volume an increased supply may frequently be obtained by opening up the spring head. It may, however, be found necessary to form a small reservoir (see par. 53, &c.), in which the water can accumulate in order to meet the extra demands made upon it at certain hours of the day; a storage reservoir is not otherwise desirable, at least, so far as the domestic supply is concerned. From whatever source, however, a supply is obtained a quantity should be stored at a height sufficient to give the requisite pressure for the supply of fire hydrant (see par. 56), as it is essential that these should be fixed at various points. Mostly, if a country house takes fire, it is doomed.

20. A land spring being in most cases dependent upon similar conditions for its supply as a shallow well, the caution given respecting pollution (pars. 31, 32) should be borne in mind.

21. *Rain Water from a Roof.*—Frequently an abortive attempt is made to utilise the rainfall by the construction of a cistern in the roof, into which the water from the several gutters is conducted. The common mistake is that the space allowed for storage is too small; the cistern is filled by the first shower, after which a much larger quantity runs to waste. The large area generally covered by the roof of a country house offers a favourable opportunity for the collection of a

supply of soft water, valuable for the laundry or for personal ablution. Owing, however, to its liability to pollution during the process of collection it is an undesirable source for drinking-water, unless very efficiently filtered. One of the chief causes of pollution in water so collected is, that large birds, such as pigeons, daws, starlings, as well as smaller birds, constantly build in or upon the roof of a country house. In the case of a roof with dormer windows that open on to the leads and gutters it is a temptation to the careless and indolent to empty bedroom slops out into the gutters. That this is very frequently done the accumulation to be found round the outlets to the rain-water pipe testify. Another danger is the liability of the water to absorb lead from the flats and gutters in its passage down the roof. Cats again are extremely fond of basking upon a roof, doubtless attracted by the seclusion and the chances of sport offered by the birds; their presence there is a constant source of pollution. The great advantages offered by a soft water for purposes of ablution and for use in the laundry make it most desirable to utilise the rainfall on the house roof wherever practicable. The roof of a large country house might be taken as an example, though it is equally desirable to collect it if only on a cottage. On a roof that covers 4000 ft. superficial area—not an excessive size for a country house—an average rainfall of 26 in. would yield a gross supply of 54,162 gallons. This, after 6 in. have been allowed for absorption and evaporation, an ample allowance on an ordinary roof, will give a net result of 41,662 gallons, or a daily supply for an average of fifteen persons all the year round of over seven gallons and a half per head. Where it is intended to utilise the rain water from a roof it is well to pass the water through some such rough filter as is shown in the illustration, Fig. 1, which will occasionally require to be cleaned out and unless periodical cleansing is practised the filtered water may become more polluted than the unfiltered. A section is shown on the line A-B. C is a 6 in. inlet pipe, D the outlet, E storm 4-in. overflow, F an air pipe between slate divisions G. H is a manhole cover, I 4 in. of coarse gravel, J 6 in. of fine gravel, K 6 in. or more of sand.

FIG. 1.



Section A B

Plan of Rain Water Filter

22. The next important point is where to store this large quantity of water. In the eastern counties the provision must be greater than is necessary in the western ones, where the rainfall is more regular. Not less than a four months' supply should be provided. Not only have long periods of drought to be considered, but in cases where the number of occupants varies from time to time it often occurs, if the tank is too small, that much of the calculated supply will be lost. In the present case it will be necessary to store 14,000 gallons. To hold this quantity a tank must be built having an internal measurement of 15 ft. *square by* 10 ft. deep; a circular tank is more readily made water-tight. If circular, the tank would be nearly 13 ft. deep. In most cases this has to be on, if not under, the ground, as the weight of water alone, over 60 tons, is too much to place upon any building unless especially prepared. Should this water be intended for cooking or drinking purposes it is far safer to have the tank raised slightly above the ground. If this cannot be done the same care must be exercised to prevent pollution as in the case of a well (see shallow wells, par. 33), or built as shown in Fig. 20. A large proportion of the roof of a country *house is over the offices and built* at a low elevation, so that if the water from them has to be collected the storage tank must be at a still lower level, and the water in any case must be *pumped up to a supply* cistern situated somewhere in the upper part of the house. The storage tank must be properly roofed over and efficiently ventilated: as far as possible, light should be excluded to prevent the growth of vegetation (par. 182).

23. *River Water.*—Rivers and streams that pass through cultivated districts are dangerous sources from which to draw a supply of water for domestic purposes as the surface water that they collect is usually heavily charged with all kinds of organic impurities. In addition to manure washed into them by heavy rains, gipsies and others commonly camp out near a stream. For example there are two or three spots on the Thames near London that will occur to the minds of many. One a little below the "Bells of Ouseley," one at Walton, and another opposite the waterworks at Hampton. One very favourite camping-ground, where often large parties come to wash their foul linen, is by the One-mile Tree, midway between Kingston and Teddington. This last, however, is below the intake. Fortunately, in a large river like the Thames the risk is much less than would be the case in one of smaller volume.

24. It may be a picturesque sight to see some bare footed Scotch girl stamping linen in a mountain stream, or a native of India swinging a shirt as though it were a blacksmith's hammer against a flat stone, but it is certainly a practice little conducive to the health of the unfortunates who drink the water lower down. One other source of pollution is the overflow or soakage from cesspools, and here again the Thames furnishes many examples.

25. At Sunbury, to mention one example, though happily now that a system of drainage has been completed there this source of pollution will cease, some fifty houses backing on to the river are each drained into one or more cesspools situated in the gardens. Some of the cesspools are but a few feet from the river's edge, which can be the only possible outlet for any overflow; this is much aggravated in times of flood. Again, on a small island just above the Broome water at Teddington, during the summer from eighty to a hundred people camp, and this island, always saturated, being but little above the water line, is for this reason a most unsuitable soil to receive the excreta of such a large population and must greatly tend to pollute the river.

26. All of us who have hung on the bridge of some quiet village have felt saddened by the way in which these otherwise beautiful streams are outraged. More frequently than not they are used as the common dustbin for the village; old shreds of metal, rags of putrid clothes, and garbage of all kinds are freely flung into them. To quote the words of John Ruskin when writing in "The Crown of Wild Olives" of similar violation in the villages of Beddington and Carshalton:—

"I have never seen anything so ghastly in its inner tragic meaning—not in Pisan Maremma, not by the Campagna tomb, not by the Torcellan shore—as the slow stealing of reckless, indolent, animal neglect over the delicate sweetness of that English scene; nor is any blasphemy or impiety, any frantic saying or godless thought, more appalling to me—using the best powers of judgment I have to discern its sense and scope—than the insolent defiling of those streams by the human herds that drink of them."

Speaking of the inhabitants he adds:—

"They having neither energy to cart it away nor decency enough to dig it into the ground, thus shed into the stream to diffuse what venom of it will float and melt far away in all places where God meant those waters to bring joy and health."

Here, indeed, is an opportunity for the parish council or other local authority to benefit, not only their own village, but every other through which the same stream flows. There used to be, and probably there still are, villages in which a very primitive form of semi-public water-closet might be seen. It consisted of a long rail in lieu of a seat projected horizontally slightly over the stream, supported by means of some forked stakes. One of these villages suffered from a severe outbreak of typhoid fever in 1872.

27. It must be considered therefore highly dangerous to use water from such sources for dietetic purposes unless most efficiently filtered. The danger of such a source of supply has been well exemplified in the outbreaks of typhoid

fever which have occurred more than once at Lynn, in Norfolk. The supply was drawn some few miles down from the spring head of a small stream which had previously passed through a district partly marshy and in parts highly cultivated. Local opinion, it is true, is or was divided as to whether this water-supply might fairly claim to have been the original cause, or whether it was not due to the defective state of the drainage of the town. Of course, in such a case it would be almost invidious to give too decided an opinion; but if only a part of the charges made against the drainage system are true it may be assumed that honours are divided, while the report of the Medical Department of the Local Government Board did not leave much doubt on the subject. The outbreak already referred to at Hamburg is another example. Without discussing the question at any great length an allusion to some of the points to which Professor Koch draws especial attention when writing upon water filtration may be of service.

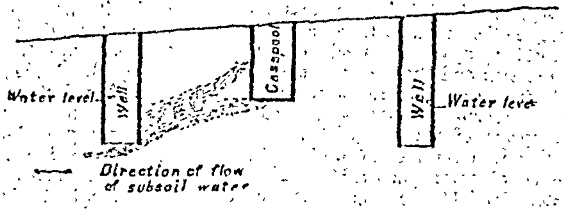
28. Of sand filtration he says: "We are compelled to admit that even under the most favourable circumstances it cannot afford absolute protection against infection, though it does afford a protection with which, considering the practical conditions of life one may rest content." He gives 30 cm. (slightly less than 12 inches) as the minimum depth for the sand layer; all dissolved matter passes through the filter. The most efficacious medium in the filter is the layer of slime deposited upon the top of the sand by the water, and this layer after a certain time, more or less according to the condition of the water and the number of bacteria present, becomes incapable of action. In summer water is particularly full of micro-organisms and this just at a time when most water is required; these clog the filter often in a few days. As a rule filters have not sufficient rest allowed them. When filtration becomes too slow this layer of slime must be removed, and until enough water has passed through to form a fresh layer of this material the effluent should be run to waste, an average of twenty-four hours being given as the time required to form this necessary layer. Thus it appears that it is one of the first essentials that this layer of slime should in no wise be disturbed while the filter is in action; this presents some difficulty as the entrance of the water, especially at first, is calculated to cause considerable commotion in the sand.

29. The rate of flow through the filter is another point that requires careful regulation. This rate is frequently calculated by a comparison of the quantity filtered in the twenty-four hours with the superficial area of the filter. Such a calculation is misleading, as the rate of flow will vary at different hours of the day according to the demands made upon the reservoir. Professor Koch gives as a maximum rate 100 millimetres per hour per square metre; he also considers that every three days the water should be bacteriologically examined, and when epidemics are imminent, or with open filters, in times of severe frost this should be done daily. In the latter case an exposed filter naturally would be rendered useless. As already stated filtered water containing more than 100 germs capable of development per c.c. should not be allowed to enter the pure water reservoir, and due provision for diverting such water should be made.

30. *Shallow Wells and Surface Water from Cultivated Ground.*—These are the commonest and in many cases the most polluted sources of supply. Their source is often surface drainage or shallow springs fed by the same. In small properties the well and the cesspool are often near neighbours. The soakage from the highly cultivated kitchen garden, the farmyard, the manure heaps, and even at times the churchyard, all adds its quota to the water in the well, as on analysis the presence of free ammonia, nitrites, and nitrates, will frequently testify. Again, small and sometimes even large animals fall into wells that are open at the top. Rats have a faculty of burrowing straight to water and will frequently make a tunnel from the old drain in which they live to the nearest well and thus form a most undesirable means of communication between them. Where, however, due care is exercised in amending their construction shallow wells may be retained and they are capable of yielding a wholesome supply.

31. The depth from the surface to which it is necessary to render a well impervious to water will depend upon the geological formation and the level of the ground water. In a light sandy soil a greater depth will be necessary than in one of a heavier character. When the ground water-line is only a few feet from the surface the well should have an impervious lining to a depth of at least 9 ft. or 10 ft. The position which the well occupies in relation to any building or possible source of pollution is also of considerable moment. The flow of the subsoil water at any given point being always in the direction of the nearest natural outlet, when such exists—as a spring, stream, or sheet of water—it is evident that the purer water will be found before it passes such possible point of pollution. For this reason, in the case of two wells situated but a few yards from each other, one may yield a pure water and its neighbour one highly contaminated (see Fig. 2).

FIG. 2.



32. It should certainly be an absolute rule that no drain, cesspool, midden, or manure heap should be within, say, fifty feet of the well, and in a gravel or very porous soil this distance should be exceeded. Again, the depth of a well affects the drainage area, for when the water in it is many feet deep the removal of this water by pumping has often a very far-reaching influence, in proportion, of course, to the density of the surrounding soil.

33. There are several ways of providing an impervious lining to a well. One is by forming a couple of single brick rings built in Portland cement and rendered on both sides in cement for a distance of some 10 ft. or 12 ft. below the surface of the soil more or less according to its permeability. This brickwork should be carried up to 12 in. above the ground level, care being taken to well puddle the space between the brickwork and the surrounding earth with clay. A second method is to reduce the opening of the well at the necessary depth with brickwork gathered over to support two or more lengths of stout cast-iron pipe 2 ft. in diameter, these to be fitted with caulked lead joints securely embedded at bottom and puddled with clay round the outside where it rests upon the brickwork, the ground round the well to be carefully rammed down at intervals, a few feet only being done at one time. There are to be obtained stoneware pipes for this purpose like enlarged drain pipes. When these are used they should be jointed in cement and puddled round the outside with clay as in the case of the brick rings.

34. It must, however, always be borne in mind that very severe frosts are liable to cause a fracture, and at such times the upper part of the well should be examined. Where good water is to be found at a depth not exceeding 150 ft., an "Abyssinian" tube-well will be found the least costly means to obtain a supply. They can be used to advantage in such soils as gravel, coarse sand, and chalk, but their use in clay soils, marls, or fine sand is not satisfactory. They cannot be driven through rock. The cost of such a well, say 100 ft. deep with a tube of 2 in. internal diameter, would be about £40. A well 20 ft. deep would probably not exceed £10, but this, of course, would depend upon the locality. Any well where the water is more than 25 ft. from the surface should be fitted with a deep well pump. There is far less risk of pollution in this form than in a dug well, provided the tube is perfect.

35. In some situations where a better supply of good water is obtainable at a lower level, an artesian well might be sunk at the bottom of the existing well, which can then be filled up. Professor Koch, in his book *on Cholera*, advises, on economic grounds, that all shallow wells fitted with pumps in dangerous situations should be *filled up*, first with coarse gravel and then with fine sand, so as to form a filter bed; the sand in such cases should be 15 ft. deep, with the perforated end of the suction pipe bedded in the gravel. The level of the ground round all wells, more particularly dug wells, should slope from and not towards the mouth, to prevent the entrance of surface water. A good plan is to enclose them in a small well-house. The pump should be within the enclosure, with only the handle and the spout accessible from the outside.

36. Another plan, and for some reasons a better one, is to have the pump fixed some little distance from the well, the top of which projects above the ground and is covered by a

large stone or iron joists and concrete cemented to render it watertight. In this case care must be taken with regard to two things :—

(1) That surface water cannot enter the well by falling back round the outside of the suction pipe.

(2) That should the distance from the well be considerable, the suction pipe must be of sufficient diameter to provide for friction in the horizontal pipe.

METHODS OF PURIFYING WATER.

37. *Domestic Filters*.—There are two principal actions that assist in the purification of water when passed through a properly constructed filter. The first is the mechanical straining of the solid particles present. The second is the oxidation of any organic matter by the atmospheric air contained in the pores of and the interstices around the medium used. Of the many filters that have been made those only dependent upon the efficient straining of the water are in any way reliable, and of these two only are known to be perfectly so, judging from a bacteriological standard. Most carefully constructed filters will, however, if constantly attended to, improve and purify water to some extent, but a neglected filter is worse than useless, fouling water instead of cleansing it.

38. *Boiled Water.*—For a private house dependent upon a doubtful source for its supply there is no protection equal to that afforded by boiling the water for ten minutes. To do this without some special contrivance is both expensive, troublesome, and unsatisfactory, inasmuch as it imparts to the water a flat and insipid taste, and although it may render it safe it certainly makes it very unpleasant.

39. In THE LANCET of Jan. 2nd, 1897, an account was given of the Lawrence process of softening and sterilising water by means of a condenser. For domestic purposes in particular this apparatus, it is said, has the advantage of being cheap, light, very portable, and not liable to get out of order. It is made in various sizes to boil from 12 to 150 gallons of water per hour; it is easily worked at a small cost; and either gas, oil, or a coal fire may be used for heating it. After careful experiments it was found to yield excellent results, the water being perfectly clear and bright, palatable yet soft to the taste, while above all it gives absolute security against infection from any water borne disease.

40. *Hard Water.*—It is scarcely necessary to dwell upon the desirability of the use of soft water in preference to hard. Economy, if nothing else, recommends it. There is a waste of two pounds weight of soap used in every 100 gallons of water that has 16° of hardness as calculated by Clark's process. Vegetables when cooked in it turn yellow and peas shrivel, but in soft water their colour is retained. Hard water compresses the pores of fresh meat boiled in it, while soft water has the opposite effect and acts as a solvent. The common cause of hardness in the water arises from the presence of bicarbonate of lime, also of sulphate of lime and sulphate of magnesia. Clark's process of softening water is the system commonly adopted by water companies who draw their supplies from the chalk. In pure water chalk is only soluble to a very slight extent, enough to impart some two degrees of hardness, but in water which holds free carbonic acid gas in solution 1 lb. of chalk can be dissolved in 560 gallons of water by 7 oz. of the gas. It is also soluble in water from an almost opposite cause—viz., by depriving the chalk of carbonic acid gas, as when it is converted into quicklime by heat. In burning 1 lb. of chalk 7 oz. in weight is lost by the loss of the carbonic acid gas driven off, the remainder, consisting of 9 oz. of quicklime, is then entirely soluble in 40 gallons of water. Clark's process takes advantage of this. The water to be softened which contains the 1 lb. of chalk per gallon is mixed with water containing 9 oz. of quicklime per gallon, when the 7 oz. of *free carbonic acid gas* which held the first 1 lb. of chalk *in solution* combines with the 9 oz. of quicklime *to form* 1 lb. of chalk, and this together with the *first* 1 lb. of chalk now no longer soluble owing to the loss of the free carbonic acid gas is precipitated at the bottom of the tank. This process is convenient and simple enough when applied on a large scale, but it is troublesome to apply for private use. There are several domestic contrivances which take Clark's process as a basis. (See also pars. 28 and 29.)

WATER-MAINS.

41. All mains should be of cast-iron, and where placed on bad or made ground must be laid upon a cement concrete bed to avoid fracture by settlement and also should be protected from contact with brick or plaster rubbish containing lime which is likely to corrode the pipes. Where laid under roads they must be *bridged over* to prevent damage by heavy traffic. All mains should be kept at least 3 ft. below the surface of the ground to preserve them at an equable temperature. With long lengths of iron pipe it may be necessary to provide expansion boxes. In laying large cast-iron mains the joints are made by packing them with yarn and then running in molten lead, afterwards driving this home with an iron caulking tool; care is required that none of the yarn is allowed to get inside the main, and as little should be used in each joint as possible. Water passing through very long mains may become contaminated through the decay of the yarn used in the joints; for many reasons it is desirable to tar all mains internally to prevent rust. Dr. Angus Smith's is the process most desirable, the pipes being coated internally with a form of black enamel while hot immediately after casting. Owing to the large amount of oxygen present in very soft water rust will very often form in masses that greatly diminish the discharge from the pipes. Difficulties frequently present themselves in laying long mains owing to the contour of the ground, and levels in all cases must first be carefully taken. No loss of head will arise through the pipes following the contour line provided they do not rise above the level of a line drawn from the highest to the lowest point. This line is called the hydraulic mean gradient. Should they do so air will accumulate at this point and loss of head will result. It should not be forgotten that a slight loss of head is caused by every bend in proportion as it is more or less acute. In deciding the size and thickness of iron mains the following points have to be taken into consideration: (1) the quantity of water required per minute; (2) the height of head; (3) the length of main for friction; (4) the height to which a jet of water is required to be thrown for fire hydrants. This last is greatly influenced by the size and shape of the nozzle used, the same head of water giving a jet greatly varying in height with different sized nozzles. It is impossible to offer in a few lines any general rule for guidance, as the several factors vary in almost every instance. With a little care by the help of a few good hydraulic tables the difficulty can be surmounted. The enormous loss of pressure by friction in long lengths of small pipes is a point too often lost sight of.

42. *Underground Waterpipes* in the vicinity of houses should be protected by being enclosed in a brick channel to prevent the risk of fracture when excavating at any subsequent time. They should never be laid in the same trench by the side of a drain, or cross one if it can possibly be avoided; should they do so they must be still further enclosed in a wooden trough filled in with pitch and be made to cross above the drain.

43. The use of lead pipes is most convenient for small mains and service pipes for house fittings, but the practice is one of too general application in view of the varying quality of the water in different localities. Iron pipes must be substituted for lead where the water is free from carbonates owing to the solvent action of soft water upon lead (see par. 10). Tin lined lead pipes found considerable favour for use with very soft water when they were first introduced, but owing to the fact that the lead was found to be acted upon by the tin they proved to be useless. The joints had to be made by means of brass connexions, and the tin lining having a much lower melting point (442° F.) than the lead pipe (617° F.) the soldering on of the brass connexions often leads to the melting of the tin. The cost of fixing also rendered it unsuitable for general use. More recently another endeavour has been made to overcome the difficulty by introducing a coating of asbestos between the lead and the tin, thus keeping the metals apart, while the non-conducting properties of the asbestos permit a plumber's ordinary joint to be made without melting the tin, but the risk from galvanic action between the tin and the lead remains.

44. In the use of iron pipes for hot water free from carbonates, as no fur is deposited on the insides of the pipes, the water is frequently discoloured by rust, being saturated with iron, so that in laundries, where a soft water is most desired, the circulating and service pipes should be of copper, or the clothes will suffer from iron mould. Where galvanised pipes are used the water becomes impregnated with the zinc, though after some little time this effect passes away.

45. *Fire Hydrants.*—It frequently happens that a house is dependent more or less for a supply of water in the event of

it is to be preferred to the enclosed, badly constructed, and badly ventilated cesspool upon sanitary grounds; being exposed to the air, and as a rule merely a hole dug in the ground, evaporation is rapid, and moreover it contains comparatively little moisture. In many parts of Devonshire, and doubtless in other counties also, closets are constructed bridging across some small stream, and such an arrangement is looked upon by the happy possessor as a great achievement. Possibly, so far as this individual is concerned, it is very satisfactory, not so, however, for the people dependent upon the stream for their water-supply lower down.

71. *Internal Cesspools.*—The occupiers of the smaller or medium class of houses, although they may suffer from the foul air from a cesspool when delivered into their house through a defective brick or pipe drain, are better off than their more wealthy neighbours in this respect. In the larger of the old country houses it was a common practice to build the cesspools *inside* the house, and it must be admitted that their construction is often a splendid example of the bricklayer's craft. In re-arranging any sanitary system in an old house search should always be made for cesspools in the neighbourhood of the bottom closet or soil pipe or in the cellar under these. Recently a cesspool was found under the floor of a large West-end mansion containing not less than seven or eight tons of solid soil. The house had been drained into the sewer many years ago and the builder who did the work was contented to only break in the top of the cesspool and cover it over with some dry rubbish.

72. In the large majority of old country houses cesspools are to be found, if not immediately underneath the house, at all events in very close proximity, the air from the cesspool being frequently drawn into the house when the fires are lighted. The distance that air may be drawn by a fire in old houses where the space under the floors and the hollow partitions, pipe casings, and wall panelling are connected together is very remarkable. This fact may frequently be noticed when search is made for the origin of some escape of drain-air, smoke, or gas.

VARIOUS METHODS OF DISPOSAL.

73. It will be better briefly to treat in order the several methods in use for the disposal of that which in the vicinity of the house cannot but be considered a nuisance: (1) the water-closet system, in connexion with cesspools to be periodically emptied or used for the purpose of irrigation; and (2) the deodorising system, either by the application of earth or chemicals.

74. The first system and certainly one which finds almost universal favour with the householder, being from this point of view the most convenient, is that of water carriage, the various so-called dry systems requiring more or less daily supervision. In either case there is a large quantity of liquid waste to be disposed of, as by eliminating the discharge from the water-closets not much more than three gallons per head per day out of a possible twenty gallons is diverted, the drainage from stables and farm buildings remaining in addition.

75. *Water-carriage.*—The water-carriage system had therefore better be first dealt with and may be thus divided into seven heads, which will serve to illustrate the means at present in vogue:—

(1) Where the whole of the crude sewage is passed on to large tracts of land, which is called broad irrigation.

(2) Where it is passed on to small tracts of land previously provided with subsoil drain and generally termed intermittent or downward filtration.

(3) Where the solid portion is precipitated either mechanically or chemically in tanks and the effluent after being again chemically treated or filtered is either passed out on to the land or is at once discharged into a stream. Of this nature is the so-called "Ferozone process," in use at Acton. The Native Guano Company in their works at Kingston-on-Thames treat the sewage of a population of some 42,000 upon a similar system. This process is installed at Wellington College.

(4) Where the whole of the sewage is passed through a strainer and the solids so caught are periodically removed and the liquid portion is either discharged on to the land or disposed of by a system of sub-irrigation.

(5) Biological filters alone or where the sewage is first passed through some form of "septic tank" and the effluent is filtered and discharged into a stream or passed on to the land.

(6) It is undesirable to pass sewage from a single private house direct into the *sea*, as for this system to be satisfactory much depends upon the set of the currents. Any attempt to carry out such a scheme properly is usually attended with great expense.

The foregoing six divisions will broadly include all the several systems in common use, though these consist of a great variety, varying in detail one from the other.

(7) Lastly, there is the old arrangement of cesspools.

76. *The Dry System.*—The second or deodorising system in which the solid excreta from the closets is dealt with apart from the liquid sewage consists mainly of the following:—

(1) Earth closets in various forms.

(2) Dr. Poore's dry catch system.

(3) The direct collection into vessels containing disinfectants.

To take the several systems in detail as applicable to the present subject.

77. (1) *Broad Irrigation* may be dismissed as being altogether unsuited to the requirements of a single house or estate. For this reason, unless the land available is well adapted for the purpose and is, moreover, of considerable extent in proportion to the quantity of sewage to be disposed of, the solid constituents present are apt to choke the pores of the earth, rendering it "sewage sick" and incapable of assisting irrigation (see par. 80). This system may, of course, be greatly helped by a suitable provision of subsoil drains and it is then called intermittent or downward filtration, No. 2.

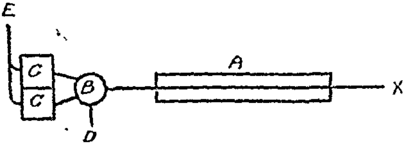
78. (2) *Intermittent Filtration* is, on the other hand, a simple and, on the whole, a satisfactory means of dealing with any considerable volume of sewage from a large estate or public institution. The land necessary to devote to this purpose may be taken in proportion of not less than an acre to every hundred of the inmates—rather more is perhaps desirable. This land is divided into plots, upon each of which in turn the stream of sewage is directed. No single dressing should be of a less quantity than one inch in depth over the whole surface of the plot, so that it becomes necessary to accumulate perhaps a week's sewage for this purpose. The size of the collecting tank and also that of the plot to be dealt with will of course be in due proportion, governed by the number of gallons available, reckoned at twenty gallons per head per day of the inmates. These plots should be six or eight in number in order that sufficient time may elapse between the dressings. The discharge is usually conducted on to the land through an annular syphon, the action of which is automatic, only the necessary attention being required to divert the stream towards the desired plot (see par. 198). The subsoil drains that collect the effluent are laid at various depths and distances according to the nature of the soil (see pars. 183 and 198). One hundred tons of sewage is required to cover one acre of land one inch in depth, which is the quantity considered necessary for each dressing, or about 22,600 gallons.

79. (3) *Where the Solids in Suspension are Precipitated.* This is effected in two ways, either by allowing the sewage to settle unaided in tanks or the processes are accelerated by the admixture of certain substances, as alumina, that fall to the bottom and entangle and carry down the more solid particles of the sewage at the same time, also to some extent acting as purifiers. The Public Health Act, 1875, requires every local authority (now the district council) to purify sewage before discharging it into a stream (Section 17). The Rivers Pollution Acts of 1876 and 1893 have also done something to prevent the indiscriminate pollution of streams, but on the whole their effect has been disappointing and the machinery provided by the Joint Rivers Boards is more hopeful. The various processes that aim at accomplishing the purification of sewage are far too numerous even to enumerate. The principle in all is invariably the same, the difference consisting in the means used. A short description of one or two systems will suffice to give a good general idea of them all.

80. The diagram (Fig. 4) shows roughly the working of the apparatus, the dimensions of course being approximate. The whole construction may be below ground if desired. A is a mixing place, into which the precipitants are thrown; B a Candy patent sewage tank; and C C, polarite filters. The sewage passes into A, where it is treated with ferozone, which contains ferrous iron salts, salts of alumina and magnesia, finely divided porous magnetic oxide of iron and finely powdered polarite,

which contains besides the foregoing silica and lime. From A it falls into the circular tank B, where precipitation takes place, and the sludge is raised by the Candy patent automatic apparatus and caused to flow out at the outlet D into a trench, where it is dug into the ground directly or removed and put upon the land. The supernatant liquid, which is fairly clear, overflows the sewage tank B into the filters C C composed of coarse gravel intersected by drain pipes laid upon the filter bottom; above this is 4 in. of fine gravel, then 6 in. of sand, then 10 in. of polarite mixed with sand, and on the top 9 in. of sand. The effluent passes out at E. The above system, though chiefly applied to the sewage of towns with varying success, has also been adapted to the requirements of an ordinary house with but few inmates. There is practically no effluvium provided the small amount of necessary attention is given, the chief point being the disposal of the sludge. In the case of a small property the effluent is dealt with by a system of subsoil drains as described for system No. 4, provided the fall of the ground will allow.

FIG 4.



81. The one objection to any treatment of sewage with chemicals is that it produces certain precipitates that delay nitrification and retard its assimilation by vegetation. Sewage so treated is always liable to secondary decomposition. The filters require to be cleansed and their contents renewed at intervals.

82. Another plan is that of the A.B.C. process, so called from the initial letters of the precipitants used—viz, alumina, blood, clay, and carbon. This method has been applied with success at Kingston-on-Thames and Aylesbury on a large scale and has been found equally successful when devoted to the purposes of a country mansion. There can be little doubt upon two or three points connected with this system: first, that the operation can be conducted without serious offence or detriment to health in a populated neighbourhood; secondly, that the guano produced has a definite market value of £3 10s. per ton; thirdly, as to the character of the effluent, in regard to which, before a select committee of the House of Commons upon private Bills, Professor J. Dewar, himself a member of the Royal Commission on the Water-supply of the Metropolis, in effect stated, in answer to questions 923 and 924, that he had examined this process in use at Kingston and was of opinion that such an effluent might safely be admitted into a stream provided the volume of water in the stream was sufficiently large and the water was not immediately intended for drinking. He thought in the case of the effluent at Kingston (which is some 1,200,000 gallons daily) that "it might pass into the Thames with perfect safety." It is, of course, the qualifying question of the possibility of the water ultimately being used for drinking purposes that renders the discharge of such effluents objectionable without having been previously passed on to the land, unless it discharges into a river below any point from which water for drinking is likely to be drawn. The case of a small effluent from a single house discharging, say, from 100 to 500 gallons daily would be different and the effluent might safely be turned into a ditch prepared as described in par. 211, as this amount would soon be absorbed, provided this ditch was at all points removed some fifty or sixty yards from any well or stream.

83. The Kingston Works on the foregoing principle may be thus described. The crude sewage in its passage to the pump well first passes through a screen, which intercepts all matters likely to clog the pumps; here it is treated with the deodorising and purifying mixtures B C. It is then raised by means of three centrifugal pumps driven by a powerful engine into a meter chamber and a record taken of its volume. From here it passes into the settling tanks, on its way receiving A, the alumina, which assists the process of clarification by the formation of a flocculent precipitate, the specific gravity of which is slightly heavier than water. The stream is not arrested in its passage through these tanks but passes out into the Thames comparatively clear. These tanks are periodically cleared of the sludge by means of pumps into a well, from which the sludge passes into accumulators by the creation of a vacuum and is then forced by air pressure at 100 lb. to the square inch into filter presses on the first floor of the building, whence it is removed in hard cakes. These pressed cakes are dried in a drying cylinder, with a fan and condensing apparatus attached, ground into powder, bagged, and sold as native guano at £3 10s per ton. Besides the foregoing arrangements there are two mortar mills for grinding the chemicals and two vats for dissolving the precipitants. Owing to the necessary outlay upon buildings and plant such a system could only be available for a large institution or mansion or where water power was obtainable.

84. (4) *Sub irrigation.*—This system is a convenient one for a small house possessing a moderate-sized garden, provided that the ground intended to be sub irrigated be situated a few feet below the level of the basement of the house to be drained. The system may be adopted omitting the catch pail, but the drain is then more liable to clog and occasionally the syphon tank will require cleansing from the sludge. The house drain after leaving the disconnecting syphon trap falls into a small brick ventilated chamber, access to which is obtained by means of an air-tight iron cover; in this chamber is suspended a galvanised wire pail, which retains the soil and paper from the water closets. This catch chamber may be situated at any point as most convenient between the disconnecting chamber and another, formed either of brickwork or iron, and capable of holding some 300 gallons of liquid, in which latter is fixed an annular syphon. This syphon when the tank is full discharges its contents into a subsoil drain formed as follows: a close jointed 4 in. drain pipe is laid from the outgo of the syphon, having on alternate sides junctions 8 ft. apart. This drain may be laid upon dry bricks put crosswise. Into the junctions are inserted branches consisting of ordinary 3 in. agriculture drain-pipes laid some 10 or 12 in. below the surface of the garden patch, also upon a bed of bricks or paving tiles, laid crosswise and flat. Each pipe is bedded upon a dab of mortar, care being taken not to squeeze any into the joints, and a similar dab is placed upon the top of each joint, thus leaving all of them open at the sides. When the syphon discharges, the whole being covered by some 4 in. of rubbish, the liquid oozes out between the sides of the joints of the agricultural drain pipes. These pipes will last for a number of years without attention; should they become choked either by accumulation or by roots it is a very simple matter to take up, clean, and relay the subsoil drain if care is taken not to disturb the bed upon which they rest. The wire pail will require to be emptied and its contents dug into the ground about once a week, not less. The objection to this system is that the drainage enters the soil below the level of greatest bacterial activity and the liquid is chiefly dependent upon the mechanical action of the earth for purification.

85. (5) *Biological Filters.*—Every age is dominated by some impressive discovery and possibly the researches into biology within the last ten years have done more to revolutionise our ideas upon things generally than the knowledge acquired in any similar preceding period of time. No fairy tale told by credulous peasant of the "little people" who labour for the good or punish the wrong doer ever exceeded in wonder the recent revelations of science. The final and satisfactory disposal of sewage in the presence of a rapidly increasing population is a subject that has an ever extending influence, not only upon the health, but upon the habits and wealth of a community. However much for purposes which we believe to be advantageous we defer the return of such sewage to the land this must be its ultimate destination. If the land is to be reproductive that which is taken from it must be returned in order to complete the cycle. This theory, though fully admitted in the case of stock and straw, is entirely ignored in the case of human beings and for this the system of water carriage as applied to sewage is chiefly responsible.

86. It is now well known that there exist in nature certain non-pathogenic organisms divided into two classes and named respectively anaerobic and aerobic, whose function in life, under the conditions that their name implies, is to convert the solid portions of animal excreta and effete

much slower process than the purification of the already liquid portion of the sewage a longer period of rest had to be allowed for this purpose in the first filter, in the construction of which preference was given to one of an anaerobic character having an upward action. An objection to downward filtration was that in time the sludge caked on the top of the filter and required to be raked over. The longer the sewage remained in this filter the greater was the reduction in the opacity of the effluent, but the most rapid filtration attempted did not permit any but the very finest particles of suspended matter to pass through. Upon the completion of the experiments very little suspended matter was found in the filter and of this about 43 per cent. only consisted of volatile solids, the rest being grit, hair, and fibres.

In sewage passed straight through this filter the oxygen absorbed by the effluent from permanganate, according to Tidy's method, was reduced about 30 per cent. After the sewage had rested in the filter for one hour the reduction exceeded 40 per cent. An increase, however, occurred in the oxidisable organic matter during the first twenty-four hours on the one hour figure, and afterwards diminished to a mean of about 20 per cent. on that of the one hour. This would indicate a reduction of unstable putrescible matter to an ultimate degree of stability more quickly than that of the more stable organic compounds to the intermediate unstable condition. Afterwards up to twenty-four hours when the amount of the unstable compounds was exhausted reduction to the ultimate stable condition only took place, with an increasing diminution of the oxidisable organic matter. The behaviour of the ammonias quite coincided with the action of the filter on the oxidisable organic matter. One curious effect was noticed—namely, that this filter under certain conditions had the power to abstract and store within itself the ammonia from the sewage. The action of this anaerobic filter was first a straining off of the suspended matter and liquefaction of the same with a partial amount of purification.

The secondary or nitrifying filters.—Of these it was said that changes which could only be expressed in terms of stability and resistance occurred repeatedly which are not indicated by analysis. As a result the importance of a number of these aerobic filters is clearly indicated. For instance, the albuminoid ammonia figure of the effluent of No. 2 filter on a certain day was 0·40 This filter had been charged with an effluent already subjected to twenty-four hours' rest in No. 1, but upon passing into and resting for an hour in No. 3 it was reduced to 0·16, or 60 per cent. Thus neither the long rest in No. 1 nor the hours' rest in No 2 had satisfactorily reduced the albuminoid ammonia, but the combined action of these two filters had so shaken the stability of the organic matter, as shown by the albuminoid ammonia, that in its passage through No. 3 filter it was reduced 60 per cent. Another argument advanced in favour of a multiplication of these filters is that the effluent first drawn off is relatively much worse than that passing subsequently, also that a filter may suddenly and unaccountably become over-taxed. A filter in its highest stage of biological efficiency will only effect a given percentage reduction on the pollution of its affluent. Supposing the pollution to be high and the filter capable of effecting a purification of 50 per cent. its effluent will still remain a filthy liquid, to be again reduced another 50 per cent. in its passage through another filter. Thus the process is continued till the desired stage of purity is arrived at. As a means of discovering the period of rest required by an over-taxed aerobic or nitrifying filter a daily estimate of the amount of ammonia eliminated per square foot of the surface of the filter was made, it being found that when this process was most active the filter was over-taxed and nitrification was practically at a standstill; and when with rest this elimination of ammonia ceased the filter was again found ready for work. Finally, the reduction of the unstable to the stable or ultimate was best effected by change of filters; that of the stable to the unstable by rest in a filter. High albuminoid ammonia, as already stated, indicated rest; high oxygen absorbed was an index for passing the effluent on to another aerobic filter.

95. *Vidangeuse Automatique.*—Upon biological lines but less exhaustively treated is M. Louis Mouras' "vidangeuse automatique," consisting of an air-tight box through which the sewage is passed and in which the anaerobic microbes are developed.

96. *Septic Tank at Exeter.*—The city of Exeter in 1896 adopted this principle with certain alterations and additions, for which Mr. Donald Cameron, the city surveyor, obtained a patent. A very full report of this tank and apparatus appeared in THE LANCET of Dec. 5th, 1896. Briefly it is as follows:—

About 90,000 gallons of sewage are dealt with daily and the installation is situated near to the town on the banks of the River Exe. With the exception of the septic tank, which is covered by a grass mound, the whole of the works may be said to be below the ordinary level of the ground.

The septic tank is 64 ft. by 18 ft., with a depth of from 7 ft. to 10 ft. and a capacity of from 61,000 to 72,000 gallons. Immediately outside the entrance to this tank is a small chamber, access to which is obtained by means of a manhole. This chamber, divided longitudinally into two compartments, is also provided with a cross weir adjacent to the tank, and into one or other of these compartments the raw sewage is turned, which allows of the one at rest being cleared of any deposit which may have accumulated. In each of these is a coarse screen, intended only to arrest any foreign object which might have gained access to the sewer. The inlets to this chamber, placed close to the bottom, being larger than the outlets into the septic tank, the sewage enters the chamber under a certain amount of pressure, thereby agitating any sediment, such as road drift, and enabling it to separate from the organic matter present; from here it flows gently over the submerged weir which divides this chamber from the septic tank. The tank itself is deprived as much as possible of light and air, and in it the sewage remains for some little time almost stationary, eventually escaping from the outlet which is situated about the middle depth. Under these conditions the anaerobic microbes multiply with such astonishing rapidity as soon to dominate the situation and unless for the entrance of fresh matter would be themselves destroyed by their own products.

By descending a manhole placed in the centre of the tank and fitted with a window may be seen a layer of floating scum containing the lighter solids, and at the bottom a thin layer of heavier sediment.

The greater part of the organic matter of the floating substance being dissolved the residue is drawn to the bottom by the ash, but here it is evidently seized upon by the microbes and a bubble of gas is formed which buoys it to the top again; here the gas escapes and it again falls; this process continues so long as any organic matter remains. The whole tank is alive with these particles and gas ascending and descending. The escaping gas being ignited the residue consists of inorganic ash upon which the microbes cannot feed; it was found that 2,000,000 gallons of sewage passing through a tank 24 ft. by 9 ft. only produced 4 in. of this sediment; a perfectly liquid effluent of a brownish-yellow tint most suitable for purposes of irrigation is the result. It is said that the action of the microbes is not interfered with by the presence of a certain amount of chemical waste from factories. At all events this is the case at Yeovil where it has been tried. Upon leaving the septic tank the liquid sewage has a slight odour, but after aeration in overflowing the sides of a V-shaped trough through which it passes on its way to the filters this odour is lost.

In the filters, of which there are five, two in alternate use and one at rest, the nitrifying organisms of the aerobic class are busy at the work of oxidation; this process is arrived at by the ammonia present being converted into nitric acid which combines with the bases present to form nitrates.

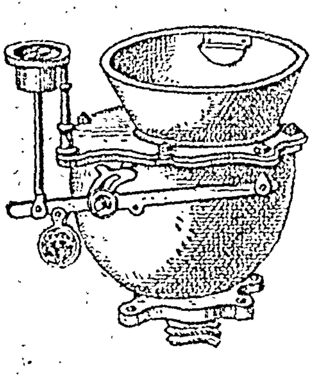
Coke, breeze, and clinkers to a depth of five feet are used in the filters and as each is charged an ingenious invention, forming part of Mr. Cameron's patent, diverts the flow automatically into the next filter and at the same time opens a valve which discharges the contents of the one just filled.

It has been found important that each filter should have a rest of one week in four. From these filters it is possible to obtain a perfectly clear filtrate containing a fifth of organic nitrogen per 100,000 parts, which is less than the amount suggested as being admissible by the Rivers Pollution Committee. Some fixed standard is desirable as to the amount of pollution that should be admitted into streams, these points being as a rule left for the decision of the chemist for the time acting on behalf of the several conservators.

97. *Dr. Poore's System.*—A description of Dr. G. V. Poore's system will be found illustrated in the treatment of the bailiff's house and lodge in the following example. The preference has been given to the water-carriage system when dealing with the mansion and other buildings, but

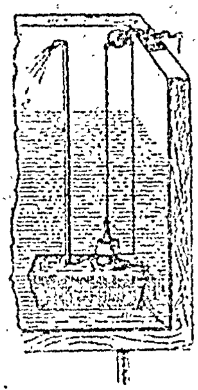
(Fig. 7) (see par. 22 of the previous report of The Lancet Special Commission on the Relative Efficiency and Cost of Plumbers' Work) and is supplied through a service-box in cistern O (see Fig. 8). There is the usual lead tray under the closet with an overflow-pipe into the D-trap (see Fig. 9) which is fitted under the closet.

Fig. 7.



Pan-closet.

Fig. 8.



Cistern and service-box.

132. *Recommendations.*—Form a window in the external wall 5 ft. by 3 ft. with double-hung sash, &c., complete. Make good the hole into the roof. Cut away for and lower the floor of this water-closet, as shown on section and plan (Fig. 12). Access to this closet will now be had by descending five steps. This will allow headway for a false ceiling to be formed over the closet and about 3 ft. below the present ceiling (see Fig. 12). A second window is to be made in the external wall between these ceilings and the sash hung on *centres* for ventilation; alter doorway and partitions to enclose closet and form new lobby. Prepare the floor and the walls for and line with white tile throughout. Provide and fix a pedestal wash-down closet with a flushing rim and an earthenware slop top fitted with a mahogany hinged seat and lid. Fix a drawn 8 lb. lead P or anti-D-trap (Fig. 10) under the same and carry a short branch of 10 lb. 3½ in. drawn-lead soil-pipe from the trap of the closet through the external wall to connect to soil-pipe G G with a 2 in. anti-syphonage pipe carried from out-go of trap into anti-syphonage pipe from closet W. Provide and fix on iron brackets in the closet some 4 ft. or 5 ft. above the basin a three gallon, silent, water-waste-preventing syphon cistern to supply this closet. Connect this cistern to the down service-pipe from cistern P by a short ¾ in. stout lead branch pipe fitted with a ¾ in. screw-down gun-metal stopcock and a ½ in. ball-valve to the cistern. Provide a ¾ in. lead overflow-pipe with brass connexion to the cisterns and carry it through the external wall. Lay on water to the basin of the closet by a 1½ in. lead service-pipe properly fixed with cast-lead tacks (see pars. 24 and 30 of the previous report of The Lancet Special Commission on the Relative Efficiency and Cost of Plumbers' Work).

Fig. 9.[2]

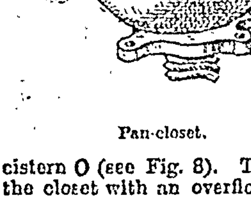


Fig. 10.

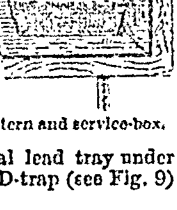
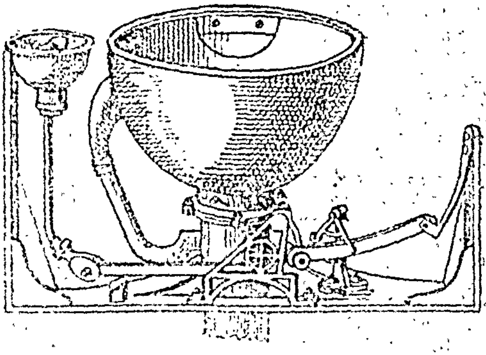


Anti-D-trap.

133. *Closet* T is of the old Bramah pattern (Fig. 11) with a fan spreader (see par. 27 of the previous report of The Lancet Special Commission on the Relative Efficiency and Cost of Plumbers' Work). Like water-closet S it has no direct communication with the outer air, having only a borrowed light from the bathroom (see plan No. 6). It is supplied from cistern O through a service box and owing to the length and smallness of the (¾ in.) pipe from the cistern the handle has to be held up a considerable time before the water reaches the pan. There is a lead safe under the water-closet which is connected with the soil-pipe of the closet; the waste of this safe is trapped in itself and is kept charged by means of a weeping pipe from the down service-pipe to the arm of the closet basin.

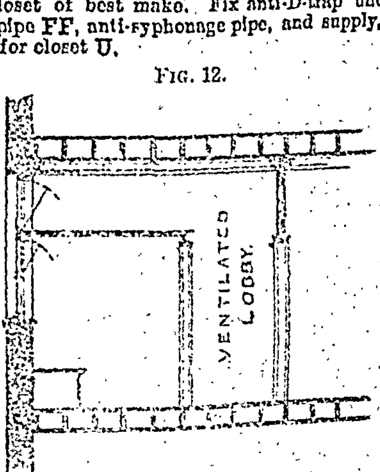
Fig. 11.



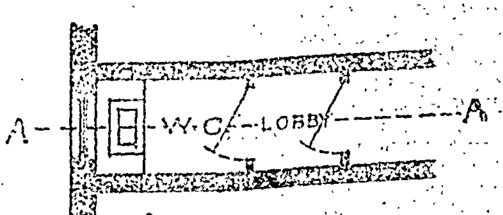
There is a D-trap under the closet (see par. 25 of the previous report of The Lancet Special Commission on the Relative Efficiency and Cost of Plumbers' Work).

134. *Recommendations.*—Remove this closet, clear away all connexions and make good the floor and ceiling. Erect a stud, lath and plaster, partition across present family bedroom, as shown on amended plan No. 9, with a 2 in. mahogany framed and glazed partition to enclose window, and form new enclosure to divide water-closet from bathroom, after the removal of old partition. Cut new doorway to connect bathroom with bedroom on east side, and provide all necessary doors, linings, skirtings, &c., to form a complete suite of rooms The lobby to the closet is ventilated as in closets S and U, Fig. 12 Supply and fix in new closet a valve closet of best make. Fix anti-D-trap under same with soil-pipe FF, anti-syphonage pipe, and supply, &c., as described for closet U.

Fig. 12.



SECTION A.A.



PLAN.

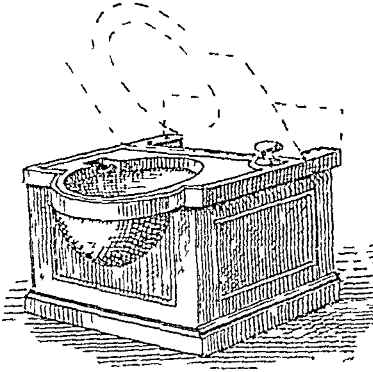
135. *Recommendations.*—Closet U (new). Form a stout stud lath and plaster partition across the end of the north-east bedroom, as shown on amended plan, with a new window of similar height to those adjoining and 3 ft. wide, fitted with double hung sashes. The lobby is ventilated by a window

---

[2] For description see par. 23 of the previous report of The Lancet Special Commission on the Relative Efficiency and Cost of Plumbers' Work.

between the present ceiling and the false ceiling enclosing water closet as in closet S Render the walls of the partition on each side down to the floor level and prepare for and tile the floor and the walls throughout Provide and fix a pedestal valve closet of the best make (see Fig 13) and lay on a 1 in branch service pipe to the arm of the basin from the new 1¼ in down service pipe from cistern P fitted *with a 1¼ in screw down gun metal stopcock under the seat* Fix an 8 lb. lead anti D trap under as in closet S and carry a stout 3½ in 10 lb drawn lead soil pipe through the external wall connected to *soil pipe* HH fix a 2 in. anti syphonage *pipe from out go of trap* connected into soil *pipe* 3 ft above level of floor, and provide and hang a French polished mahogany seat and lid

FIG 13



136 *Closet* V is similar in all respects to closet S but is *provided* with *ample* ventilation and light, having a good window Owing however, to the defective condition of the plastering and to the openings between the floor boards skirtings, &c, whenever this closet is used a smell is drawn into the adjoining bedroom as is proved by the fact that smoke can be passed from this closet freely into the bed room

137 *Recommendations* —They are in all respects the same as for water closet T excepting the treatment of the anti syphonage pipe which is the same as closet U

138 *Closet* W is somewhat badly placed (see plan No 5) opening as it does directly into the billiard room The closet is of the kind known as a side wash out, with pan and trap in one piece of earthenware (see par 29 note *L* of the previous report of THE LANCET Special Commission on the Relative Efficiency and Cost of Plumbers Work) It is connected with a 6 in drain pipe continued down to the cellars and carried into the cesspool at the foot of the rain water pipe D

139 *Recommendations* —The position of this closet would be much improved if it were arranged as shown on the amended plan No 8 by which means a ventilated lobby is placed between it and the cloak room The doorway on the water closet side of the billiard room must be filled in with wood studs and lathed and plastered and the floor and the walls of the closet and the lobby must be prepared and tiled throughout Notice that the cloak room in this case has to depend upon a borrowed light being enclosed upon two sides with a glass partition The closet is to be replaced by a good pedestal wash down closet, with an 8 lb lead syphon trap Carry a stout length of 4 in 10 lb lead soil pipe from the trap through the external wall at the ground level with brass thimble (see Fig 14 also par 36 of the previous report of THE LANCET Special Commission on the Relative Efficiency and Cost of Plumbers Work) on end to connect into short iron drain to man hole Carry up the usual anti syphonage pipe described in par 150 provide a flushing cistern lay on water to the same with a stout branch of ¾ in lead pipe from the down service pipe from cistern P provide a stopcock, &c, make seat and lid, and in all details finish as described for water-closet T

FIG 14

Thimble.

140 *Closet* X is a pan closet supplied with water from cistern Q through a valve under the seat *The D trap below* is connected with the rain water pipe J by a stout branch of 4 in lead pipe It is not provided with a lead safe which in this case is unnecessary There is a good window for light and ventilation, but owing to the outlet of the gutter of the roof over the kitchen being just underneath the sill there is the risk of bad air entering from the foul soil pipe J At times this closet is useless, owing to its defective water-supply

141 *Recommendations* — Replace the closet by one with a short hopper basin having a flushing rim The basin is fitted into a lead cone and fitted into an 8 lb lead P trap Fix an earthenware slop top and a mahogany French polished seat and lid both to be hinged Continue a short length of 3½ in 10 lb drawn lead soil pipe through the external wall This is to be connected into soil pipe J (par 117) with an anti syphonage pipe as described for closet U Provide and fix on brackets a cistern fitted as described for closet S Prepare for and lay tile floor It is not so necessary to line these walls with tiles if they are properly plastered down to the floor the walls being of 14 in brickwork Make good the skirting round the back of the closet and the linings after the alteration to the window. Cut away and form a skylight in passage where shown by *dotted lines*

Note K—Care is required in selecting these closets as some of this shape are liable when flushed to form a vortex in the trap which is then cleared with difficulty

142 Closet Y. *Recommendations —Increase size of present* doorway and form brick arch Set back external door and frame to form lobby as shown on amended plan No 8 The dark cupboard under the servants' staircase is to be studded *round* at the back and one side is to be lathed and plastered and the cupboard, floor and walls are to be prepared and tiled throughout A window about 2 ft 9 in by 4 ft is first to be cut in the external wall and fitted with double hung *sashes* glazed with obscured glass There being insufficient headway under these stairs above the water closet in which to fix a flushing cistern a good valve closet (see Fig 15 also par 26 of the previous report of THE LANCET Special Commission on the Relative Efficiency and Cost of Plumbers Work) is to be provided and fixed facing the new window A 1 in branch pipe is to be connected with the service pipe to water closet W and is to be fitted with a screw down wheel stop cock under the seat of the water closet Provide a French polished mahogany hinged seat and *a lid with a moveable riser or front* Provide and fix an 8 lb lead syphon trap (Fig 16) under the water closet, this being connected with the heavy cast iron 6 in soil pipe by a brass thimble (see par 35 of the previous report of THE LANCET Special Commission on the Relative Efficiency and Cost of Plumbers' Work) and carried through the external wall into the manhole Should it be possible to connect a 2 in syphonage pipe into that from water closet W a

FIG 15

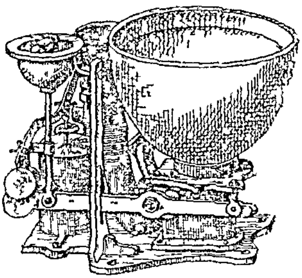


FIG 16

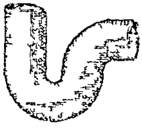
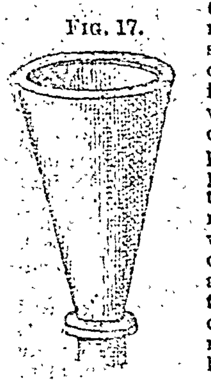


Syphon trap

drain will suffice. Fix a short piece of 2½ in. thick York stone to support the brickwork where the pipe passes through the external wall.

143. *Closets* **AA**, **BB** (see plan No. 5) are intended for the servants' use, **AA** being for women and **BB** for men. They are fitted with hopper pans and fan flushes (Fig. 17, see par. 31 of the previous report of THE LANCET Special Commission on the Relative Efficiency and Cost of Plumbers' Work) and are supplied from cistern **R** by means of cottage valves fixed under the seat. They discharge by a short drain-pipe into cesspool. The foregoing on reference to plan No. 5 will be seen to be an objectionable not to say indecent arrangement, in frosty weather, when no water is available, the state of these closets must be very bad. By the alteration shown on the amended plan these closets are still retained as earth closets for the use of the men servants; **EE** is added at kitchen entrance for women and **CC** and **DD** are provided for the use of the male occupants of the mansion and are screened from the gardens by shrubs.

FIG. 17.



144. *Recommendations.*—The old closets are to be removed, together with all the old drains in connexion with them, also any wet earth, which last is to be replaced with good dry brick rubbish or available dry earth, and covered with 4 in. of cement concrete after the alterations shown on the plan (No. 8) have been carried out. Cement the wall and floor, this last finished with a slight fall to back of closet, and line with tiles. These closets are raised upon two brick steps, and are not provided with any form of apparatus other than a box at the side to hold dry earth, together with a small shovel with which to throw it over the dejecta, and it is well to keep a hearth-brush in the closet for the removal of any earth that falls upon the seat. The floor of the catch under the seat being cemented one or two shovelfuls of earth are sprinkled over the same after each removal of the soil. This absorbs the urine. Every day or every week the accumulation is removed through a large trap-door at the back of the closet. This door has a space of some 3 in. at the bottom to allow of a free circulation of air. These closets, if regularly attended to, are entirely free from any objectionable smell and the humus derived from them will be found to be unequalled as a manure for the garden (see Plan 8, also par. 209).

145. *Closet* **EE**. *Recommendations.*—Provide and fix a pedestal closet with a bottom outlet (see Fig. 6 in the previous report of THE LANCET Special Commission on the Relative Efficiency and Cost of Plumbers' Work) and an 8 lb. lead syphon trap. Supply and fix on brackets a 3-gallon silent water-waste-preventing cistern connected with the closet by a 1½ in. service pipe. Lay on water to this cistern by a ¾ in. branch pipe from the service-pipe to water-closet and put a ½ in. ball valve in the cistern. This service-pipe is to be fitted with a ¾ in. screw-down stop-cock close to the flushing cistern. Carry a ¾ in. lead overflow-pipe through the external wall. Connect the outgoing pipe of the trap to a stout iron drain-pipe, all to be as described for water-closet **O**. The floor and the walls are to be prepared and lined with tiles throughout.

146. *Soil-pipe* **D** has already been described (see par. 111). It receives the contents of closet **T** and sink **JJ**, and the waste water from bath.

147. *Recommendation.*—This pipe will be removed entirely and a new 3½ in. 10 lb. lead soil-pipe **FF** is to be provided and fixed to connect with closet **T** with six 7 lb. cast-lead tacks to each 10 ft. length of pipe, the tacks being placed in pairs at equal distances apart. The bottom of the soil-pipe is to be connected by a brass thimble with the iron drain to the manhole. The branch soil-pipe from closet **T** is to be connected, the pipe is to be carried up and finish about 3 ft. above the curb roof and is to be properly secured by an iron stay. A copper-wire guard is to be fixed on the pipe with a 2 in. anti-syphonage pipe from outgo of trap connected to soil-pipe 3 ft. above floor level.

148. *Soil-pipe* **GG** is a 4½ in. seamed lead pipe which is carried down internally and receives the discharge from closets **S** and **V** as well as the waste water from the housemaid's sink **KK**. It is unventilated, and the longitudinal branch connexion with water-closet **V** is much corroded and perforated (see note *N* in the previous report of THE LANCET Special Commission on the Relative Efficiency and Cost of Plumbers' Work). It dips into a small brick pit at the foot, and is connected with a cesspool by a brick drain passing under the lobby of the dining-room.

149. *Recommendation.*—Provide and fix a new 3½ in. drawn-lead soil pipe **GG** connected to water-closets **S** and **V**, finished in all respects as described for the last closet, excepting only the anti-syphonage pipe, which is as follows:—

150. *Anti-syphonage Pipe.*—A strong 2 in. lead anti-syphonage pipe (see note *O*, par. 37 of the previous report of THE LANCET Special Commission on the Relative Efficiency and Cost of Plumbers' Work) is to be fixed at the side of this soil-pipe with cast-lead tacks weighing 4 lb. each, one pair of tacks being used for every 3 ft. 6 in. of the pipe. The bottom of this pipe is to be connected with the outgoing pipe of the trap of water-closet **W** with branches to the traps of closets **S** and **V**. The upper end of this pipe is to finish about 3 ft. above the curb roof and is to be secured by an iron stay. A copper-wire guard is to be fixed on the top of the pipe.

151. *Soil-pipe* **HH** is new. It is similar to the last and is connected with the branch from water-closet **U**. It finishes some 3 ft. above the coping. The anti-syphonage pipe is carried from the trap of closet **U** and is connected into the side of the soil-pipe 3 ft. above the branch connexion of the closet.

152. *Soil-pipe* **J**.—This has been described in par. 117.

153. *Recommendation.*—A new soil-pipe (described in par. 118).

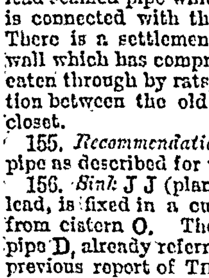
154. *Soil-pipe* **II** from water-closet **W** is a short 4½ in. lead seamed pipe which passes through the external wall and is connected with the drain communicating with cesspool. There is a settlement where this pipe passes through the wall which has compressed the pipe. The pipe has also been eaten through by rats, thus forming a means of communication between the old brick drain and the interior of water-closet.

155. *Recommendation.*—This will be replaced by an iron pipe as described for water-closet **W**.

156. *Sink* **J J** (plan No. 7), which is small and lined with lead, is fixed in a cupboard on the landing and is supplied from cistern **O**. The waste-pipe is connected with soil-pipe **D**, already referred to in par. 111 (see also par. 35 of the previous report of THE LANCET Special Commission on the Relative Efficiency and Cost of Plumbers' Work). There is a small D-trap under the sink, but the waste-pipe is unventilated.

157. *Recommendations.*—A doorway into the adjoining box-room is to be formed after the removal of the present enclosure to the sink and a moulded four-panel door and frame are to be provided and hung. A quarter framed partition is to be fixed to divide the box-room and to enclose one window, to convert same into a second bath-room and a housemaid's closet; the existing doorway is to be shifted as shown on amended plan No. 10; lath and plaster the partition on both sides down to the floor, and provide and fix skirting round the same to match existing ditto. There is also to be provided and fixed upon proper bearers under the window a white glazed earthenware sink 2 ft. 6 in. by 1 ft. 6 in. and a 1½ in. strong lead waste-pipe from the same is to be carried through the external wall, with a lead syphon trap fitted with brass cleansing screw fixed under the sink. A 1¼ in. short anti-syphonage pipe is to be connected to the outgoing pipe of the trap, terminating just outside the external wall, and a cross-wire guard is to be fixed over the end of the same (Fig. 18). A 2½ in. galvanised cast-iron pipe **UU** is to be supplied and fixed externally, the upper end standing some 2 ft. above the parapet wall and the lower end being fitted with a shoe to half channel laid to gully. A junction in this pipe is to be fixed to receive and connect the waste-pipe of this sink and bath waste-pipe. A wire guard is to be fixed on the top of the pipe. All the joints are to be made with yarn

FIG. 18.



and it is necessary to red lead the ends, and the sockets of each pipe are to be painted before fixing A ¾ in stout lead service-pipe is to be laid on to this sink from the down service pipe from cistern **H** fitted with a screw down horizontal bibcock Also a similar ¾ in stopcock is to be fixed in the service pipe to the sink The floor of this closet under the sink should be covered for a space of 5 ft by the full width with 7 lb lead, close copper nailed round and across

Note L.—The use of lead pipe for long lengths of bath or sink wastes on external walls is better avoided unless expansion joints are provided above and below the junctions of all branch pipes into same

158 *Sink* **KK** (Plan No 6) is lead lined and has a 1 in waste pipe trapped in itself The sink is supplied from cisterns **P** and **Q** and the waste water is carried into soil pipe **GG** Occasionally the trap syphons out when closet **V** is used

159 *Recommendations* (Plan No 9)—Remove sink and provide a sink as described for sink **JJ**, and fix by window connected with waste pipe **TT** and finished in all respects similar to **JJ**.

160 *Sinks* **LL, MM, NN, OO, QQ, RR,** and **SS** are all lead lined and are of various sizes Cold water is supplied from cistern **R**, soft water from cistern **Q** and hot water from cistern **P** All these sinks are immediately connected with the drain, the waste pipes dipping into brick built traps

161 *Recommendations* —The sinks marked **LL, MM, QQ, RR,** and **SS** are to be fitted with fire-clay enamelled sinks about 24 in by 16 in, having 1¼ in lead waste pipes carried over external gullies and fitted with syphon traps with cleansing screws Each trap is to have an anti syphonage pipe as described for sink **JJ.** The cold services are to be taken from the 1 in service pipe from cistern **O** to the hot water cylinder in the kitchen, with ¾ in horizontal screw down high pressure bibcocks to each sink A similar stopcock is also to be fixed in each service Sinks **NN** and **OO** are to be of wood, with a division in the centre, about 3 ft by 1 ft 6 in and 1 ft deep They are to be lined with pewter and in other respects are to be treated as the last excepting that there is to be in each division a brass washer and plug Either side of these sinks is to be provided with a grooved draining board, the whole covered with pewter The present service to small feed cistern boiler in servants' hall must be reconnected to down service from **O.**

162 *Sink* **PP** (scullery) is a large stone sink (see note *O* in the previous report of THE LANCET Special Commission on the Relative Efficiency and Cost of Plumbers' Work) supplied from cisterns **R** and **Q**, the present arrangements of which have been described under cistern **R.** (See par 129)

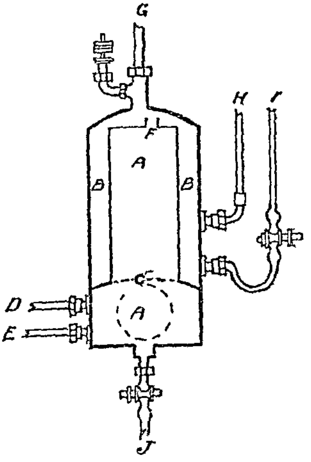
163 *Recommendations* —The scullery is to be partitioned off as shown on the amended plan No 8 to form closet **EE** with open lobby and passage to the kitchen, the windows in the scullery being now appropriated by the water closet A new one must be formed looking into the new side entrance passage to light and ventilate the scullery The partitions are to be built of 9 in brickwork The interior of the scullery and the larders is to be cemented and lined with white glazed tiles, but the remaining portions of the partitions can be finished in plaster The floor throughout should be paved with brick or Dutch tiles laid on a proper concrete bed A small lean to roof is to be placed as indicated on plan No 9 to shield larder windows from the western sun, and an extra sash is to be fixed in the end larder Provide and fix a glazed stoneware sink **PP**, 3 ft by 1 ft 8 in, placed on dwarf brick walls, with a 2 in stout lead waste pipe carried through the back wall chased in the same to deliver into flushing gully Fix under the sink a lead syphon trap fitted with a brass cleansing cap and screw A 1½ in anti syphonage pipe is to be connected just by the outgoing pipe of the trap and is to terminate externally, the end of the same is to be protected by a wire guard Provide a ¾ in screw down bibcock and connect with a stout ¾ in lead branch pipe from the 1 in down service pipe from cistern **H** A screw down stopcock is also to be fitted in this short service pipe Provide and fix under the plate rack a draining board covered in pewter to drain into the sink Should other sinks for washing vegetables be necessary they can be had in stoneware and treated in the same manner as the last delivering by separate waste pipe into the external gully

Note M.—Where as in the present instance a biological filter is used the fat must be kept out of the drain or the filter will become clogged An earthenware fat-trap gully must be substituted for the flushing gully and the accumulations removed and superficially buried at regular intervals

164 *Hot Water System* —There is a circulating system from the boiler in the kitchen to a tank fixed in the housemaid's closet on the first floor half landing The expansion-pipe is turned through the external wall (see par 52 of the previous report of THE LANCET Special Commission on the Relative Efficiency and Cost of Plumbers' Work) A small supply cistern at the side of the tank furnishes the supply, being connected by a ball valve to cistern **P**; the overflow pipe from this small cistern is connected into the waste pipe of the sink above the trap There are draw off taps at the bath and to sink **KK** and all those on the ground floor excepting in the servants' hall

165 *Recommendations* —Provide and fix in the recess at the side of the kitchen range a 50 gallon galvanised iron circulating hot water cylinder connected to the boiler by 1½ in flow and return steam pipe (see Fig 23 in the previous report of THE LANCET Special Commission on the Relative Efficiency and Cost of Plumbers' Work). Carry up from the top of the boiler a 1¼ in steam pipe and bring the same through the wall of the chimney breast and fit with a dead weight safety valve. Fig 19 shows a Lawrence patent cylinder and its object is to limit the amount of incrustation in it and the pipes by using the water in the boiler only for the purpose of heating that in the cylinder Its description is as follows **A** is an internal chamber rising from a diaphragm **C**, below which are connected the flow pipe **D** and return pipe **E** from the boiler, access to this chamber is provided for by means of a manhole **F** is an open tube passing up to within about half an inch of the top of the outer jacket of **B** and serves to connect the two chambers **A** and **B**, the pressure of water of course being the same in each Though thus connected it is found in practice that the two waters do not mix to any appreciable extent owing to the variation of temperature causing a difference in gravity **G** is the flow pipe to the bath, &c, and **H** the return pipe to the cylinder, **I** being the cold supply pipe from cistern **O.** Through this arrangement after the salts contained in the water in the boiler and in the heat interchanger or chamber **A** have been thrown down, comparatively little additional deposit takes place The water, however, from this or from any other form of circulating apparatus cannot be regarded as having been sterilised by heat owing to the great pressure generally present necessitating a much higher temperature than is required in an open vessel to raise the water to the boiling point The use of such a cylinder as above described

FIG 19 (Par 165)



is by no means a necessity where a steriliser is fixed (see par. 130), as nearly all the salts of lime and magnesia will have been eliminated previously to the water entering the boiler. The 1½ in. flow-pipe from the cylinder divides into two 1 in. steam pipes, one pipe passing along inside the front external wall of the wing and the other inside the back external wall, branches being carried down on each side to the several sinks; by this arrangement the presence of long lengths of branch pipes with dead water is avoided. Each sink is fitted with a ¾ in. gun-metal high-pressure, screw-down, horizontal bibcock. These two flow-pipes again unite at the end of the passage and pass up through the lavatory, housemaid's closet, and along the wall of the passage on the first-floor to the best bath-room, with branches to this bath, and the one on the second floor also to lavatory, servants' bath, and two housemaids' sinks, which last are provided with ¾ in. screw-down bibcocks like the others. The flow is continued up through the new housemaid's closet and is returned by a single pipe into the cylinder. An expansion pipe is carried from the highest point and is turned over cistern I in the cistern room. Provide a small expansion cylinder in this pipe above the level of the top of the cold-water cistern.

166. *The Best Bath* is composed of zinc enclosed by a mahogany framed casing. There is a lead safe below, the waste-pipe from which passes into the side of the D-trap of water-closet T. The bath waste-pipe is fitted with a running trap formed in the 1½ in. waste-pipe and is then connected with soil-pipe D. The bath has a hot and cold supply, the latter from cistern H and the former from the hot-water tank in the housemaid's closet; this supply is very sluggish, the head of water in the hot-water tank being but little above the bath. The supplies enter at the sides through two 1 in. plug stopcocks under the bath. There are worked by iron rods and lever handles. Owing to the cocks leaking and the *inside of the bath becoming rusty* the lead pipe between the cocks and the inlet to the bath has been punctured to allow of the escape of any water passing the valves when shut, occasioning considerable waste of water.

167. *Recommendations.*—Disconnect the bath, make good the inlets, and fit a plug waste in the bottom of the bath; re-enamel and re-use the bath in the servants' bath-room. Disconnect the waste-pipe of the safe from the D-trap which is to be removed and carry a 1½ in. lead waste-pipe through the external wall to deliver into the open air. Fit a copper flap-valve at the end of the pipe. Provide a new full-sized parallel enamelled copper bath and fix it with a vulcanite plug and plated fittings to the waste-pipe connected to the 1½ in. lead pipe and running trap; the waste-pipe is to be carried into waste UU from sink JJ. Take from the out-go of this waste-pipe a 1½ in. lead anti-syphonage pipe carried through the external wall fitted at the end with a copper-wire guard. Provide hot and cold overhanging screw-down plated cocks and connect with 1 in. galvanised iron pipes *respectively from* the down service-pipe from cistern O, and the hot-water system each fitted with screw-down stopcocks near the bath. Supply and fit a new mahogany bath top, refix bath casings and make good the floor, walls, and skirtings. Provide and fix a 1½ in. plated overflow at foot of bath having a lead waste carried through external wall, the end fitted with a copper flap-valve.

168. *Second, or Visitors' Bath.*—Supply an independent cast iron best enamelled bath, with plug waste properly trapped with anti-syphonage pipe carried through external wall and connected into that from best bath. Fix wood fillet on floor and cover space under bath with 7 lb. lead. Carry 1 in overflow through external wall, the end fitted with a copper flap valve. Lay on 1 in. galvanised iron service from down service from cistern O fitted with screw-down stop-valve by bath. Supply screw-down overhanging plated bib-valve at foot of bath and connect to same, also a similar valve for hot water and connect with 1 in. galvanised iron service from hot-water circulation, fit overflow grating to foot of bath and carry ½ in. short lead pipe to project through external wall—the end fitted with a copper flap-valve.

169. *The Servants' Bath.*—Provide a lead safe with a 1½ in. waste-pipe carried through the external wall, fix the old zinc bath and fittings taken from the principal bath-room, carry a 1½ *in. lead waste-pipe* TT into waste of sink KK and fit a running trap in the same with an anti-syphonage pipe as in the last bath. Provide lead safe and waste into open. Lay on overhanging hot and cold supply-pipe with brass screw-down bibcocks, each service provided with stopcock as last. Provide deal top and matched boarded enclosure to bath, fitted with door for access to safe.

Note N.—*Happily the greater facilities* for cleanliness now provided in the homes from which domestic servants are taken, together with similar opportunities offered in houses where they are employed, is producing a taste for more healthy habits among this class than prevailed formerly. It is not at all uncommon to find members of the families of the better class of mechanics who have never had a bath *that they can remember unless owing to the accident of illness.* The condition of these people when becoming inmates of a hospital proves this frequently.

170. *The Lavatory.*—After the alteration to the cloak-room has been carried out provide and fix under the window with moulded edge a white marble slab 1½ in. thick, the full length of opening by 1 ft. 9 in. deep fitted with two oval lavatory basins under the same, with a separate 1 in. overflow-pipe carried through the external wall to deliver over gully. Provide and fix a pull-up waste valve and connect a 1½ in. drawn-lead syphon trap under each basin and continue the waste-pipes through the external wall to deliver into gully. Provide a 1 in. anti-syphonage pipe from the outgoing pipe of the traps to finish externally, the end being fitted with a cross-wire guard. Lay on 1 in. galvanised iron cold supply-pipes fitted with overhanging cam action plated bibcock and connect a 1 in. branch pipe from the hot-water service pipe to similar bibcocks. Provide 1 in. stopcock as before described in each service-pipe.

Note O.—It is very desirable that each internal closet should be approached by a ventilated lobby, but this in all cases is not obtainable. A more complete plan than the one adopted would have been to build an annexe at the back of the house to contain all the closets and the bathrooms, but this would not have been so applicable to the general requirements of the public.

THE WATER-SUPPLY.

171. *Existing Water-Supply.*—There is a constant spring from the hills some 300 ft. above the house, the water from which is collected in a reservoir 150 ft. lower down. The overflow from this reservoir falls into the lake, the stream through which then passes on through the village which is a mile distant. This reservoir is silted up and requires thoroughly cleaning, embanking to exclude surface water, and fencing round. (See Water-storage, par. 53, &c.) *The service-pipe to the mansion has only* a 1½ in. bore and is altogether inadequate to the requirements. In addition there is a deep well by the bailiff's house and there is another at lodge No. 5 whilst a shallow well supplies lodge No. 8. (See plan No. 12.)

172. *The Main Supply.*—Form a *brick chamber 3 ft.* by 3 ft. 6 in. and of the necessary depth at the side of the reservoir to form a manhole for a stop-valve in the main. Connect into the reservoir 6 in. from the bottom at this point a 4 in. heavy cast-iron main laid with the usual molten and caulked lead joints carried to a point about 20 ft. from the north-east angle of the building, where it divides into two 3 in. branches, one passing along the south-west front of the house as far as the end of the kitchen wing and the other along the garden or north-east front to a hydrant at the extreme corner of the stables. From this point a 2 in. main-pipe is carried at the side of the road past the greenhouse as far as the farm buildings, where another hydrant is to be fixed. This main must be laid in a *trench at least 3 ft. deep,* it must be carried in a straight line from point to point, and be (see par. 41) of even fall throughout. In the immediate neighbourhood of the house and buildings and wherever passing through made ground it must be laid upon a 6 in. concrete bed. This main pipe will have 2 in. branches to hydrants fixed at suitable points all round the house at about 20 ft. or 30 ft. from it. A 2 in. strong lead branch pipe will also be carried up to the level of the second floor to a point outside water-closet S. Two other points will be provided, one in the cloak-room and the other by the doorway in the passage on the first floor connecting the main and the wing buildings. These points will be fitted with handy straightway lever valves (Fig. 3) and the usual hose and connexion. A ¾ in. stout lead branch rising main will be continued from this main to supply cisterns O and P fitted with equilibrium ball valve.

SUMMARY OF EXISTING ARRANGEMENTS FOR THE DISPOSAL OF SEWAGE.

173. *The House, Stables, and Laundry* (see plan No. 12).—There is an entire absence of any regular plan of drainage, the house having under and around it a number of cesspools the overflows from which are carried into the surface-water

drain from the garden paths, which last eventually delivers into a ditch running at the side of the avenue and falling into the stream that feeds the lake. The bulk of the solid matter is caught by the cesspools, while much of the liquid soaks into the ground from the defective drain and during its lengthy passage in the ditch, but little fortunately reaching the lake excepting during heavy rains.

174. *The Gardener's Lodge (No. 5) and Farm Buildings* drain into the ditch on the north-west side of the road.

175. *The Bailiff's House (No 6)* has midden closets, and the surface drains run into a ditch.

176. *Kitchen Gardens'* surface drains run into the pond in the garden.

177. *The Keeper's Lodge (No 8)* drains into a cesspool.

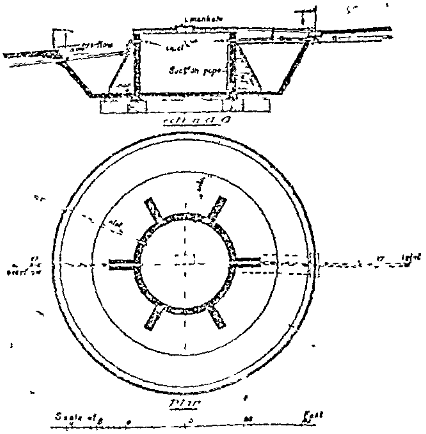
178. *Recommendation.*—The general system of proposed drainage is as follows, the details being given under different heads.

179. *The several Soil Drains* round the house (see plan No. 11) are collected in a disconnecting chamber marked 9 on plan No. 12 (*see also Fig. 21*); a drain passes under the terrace road to a point opposite the entrance to the stables; here it turns almost due west and joins the back road by lodge No. 6. From this point it runs in a direct line to the Moncrieff cultivating tank E. In its course it receives the soil drain from the laundry and stables, Nos. 2 and 3, and the connexion with the pond, lodge No. 5, and farm buildings No. 7. Further details relating to these buildings will be found under separate headings

180. *The Surface Drains* are formed entirely separate from the last and are collected so as to deliver half into the pond in the kitchen garden, while half passes into the hawhaw adjoining the drive. From this pond an overflow-pipe is carried into the ditch on the north-west side of the back road. There is also a connexion, fitted with a disconnecting chamber and sluice valve, between the pond and the main drain, to be used occasionally for flushing purposes. The rain-water overflow and the surface drains in the basement of the house deliver over gullies in connexion with this surface drain.

181. *The Rain water Drains* —Before discharging the rain-water into the storage tank it should be passed through a sand and gravel filter that will free it from any gross impurities which may have accumulated during the process of collection. The illustration (Fig. 1) shows a simple form of construction for this purpose. It will be necessary to provide a storm overflow for the ready escape of any large body of water which would be unable to pass through the filter.

FIG 20



182. The plan (Fig. 20) shows a good form of rain-water reservoir, but in the event of another suitable supply being available it would be undesirable to entail the outlay necessary for its construction. In the present case it is given simply as an illustration. The use of the steriliser marked Z on plan No. 8 provides a soft water equal to all requirements and the collection of rain-water is unnecessary. The plan and section (Fig. 20) sufficiently explain the principal details. This reservoir consists of a circular tank built in brickwork in cement supported by buttresses, the bottom of which is kept a few inches above the level of the surrounding area. The tank is covered over on the top, in the centre of which is fixed a ventilated louvre manhole—the whole is lined with Portland cement. Access to the tank is had by means of a short foot-bridge, which also carries the main inlet drain. The whole is surrounded by a light railing.

NOTES ON THE DRAINAGE SYSTEM.

183. *The Levels* —The first consideration of any system of drainage is one of levels, and where irrigation is to be adopted a fall of a few additional feet will be required. A large house, for instance, like the example given would need a fall of from 25 ft. to 30 ft., and as a rule this class of house is so situated as to admit of such a fall being available. If this is not the case a small cesspool or sump must be formed and the sewage must be raised by an elevator with the best power available. The fall will be divided somewhat as follows :—1. From the house to the cultivating tank, with an allowance for falls in disconnecting chambers, say a 500 ft. run of drain with a minimum fall of 1 in 60 = 10 ft. 6 in., commencing at a depth of 12 in. at the highest point below the ground line. 2. The depth of the cultivating tank and the storage reservoir with the fall for the drain between would amount to 9 ft. 6 in. 3. The land to be irrigated should have a fall, however slight, and the subsoil drains, which will be laid about 2 ft or 3 ft. below the ground line, must have a slight fall ; this may be taken altogether at not less than 5 ft. 4. Beyond this a subsidence pond is desirable from which an overflow passes into a stream or ditch ; this may be put at 2 ft. In connexion with this overflow not only must the normal level of the stream be considered, but also its possible rise when in flood. At this point, under some circumstances, it may be desirable to provide a gully fitted with a float valve to check the back flow. The rain-water from the house and the grounds, it is remembered, is dealt with by a separate system, where a less total fall is required. The total of these falls is made up thus : No. 1, 10 ft. 6 in. ; No 2, 9 ft. 6 in. ; No. 3, 5 ft ; and No. 4, 2 ft. ; the total fall being 27 ft In order to economise the fall, most of which is required at the extreme end, it may sometimes be necessary to support the main drain upon a brick wall or embankment, or even upon a stout tressel rustic viaduct, when passing across some depression of the contour line of the ground. Of course, in such cases heavy cast-iron drain pipes would be used.

184. *The Size of the Drain* —It is a mistake to use too large a drain ; one of 6 in. diameter will generally suffice for the requirements of the largest house, a small drain being more readily kept free from deposit

185. The following table[3] from some calculations made by Messrs. W. Santo Crimp and A. M. Bruges shows the inclination to be given to circular pipes flowing full or half full in order to produce a velocity of flow equal to 3 ft. per second, together with the discharge in gallons per minute when flowing half-full.

Diameter of pipe	Velocity per second	Inclination.	Discharge (half-full) per minute.
4 in	3 ft	1 in 62	49 gallons.
6 in.	3 ft	1 in 107	110 ,,
9 in	3 ft	1 in 183	248 ,,
12 in	3 ft.	1 in 269	441 ,,
15 in.	3 ft	1 in 362	690 ,,
18 in	3 ft	1 in 462	993 ,,

In providing for the removal of surface water the following tables are generally accepted, but the great variation in the amount of rainfall in different localities renders it impossible to offer any universal rule in this matter.

---

" grass "	0·02 "

186. *The Old Drains.*—All old internal drains must be carefully traced to see whether they lead to any cesspool and must be removed, together with any contaminated earth. Even external drains should be carefully removed, as they may contribute to the pollution of water.

187. *Made Ground.*—In made ground all pipes must be laid upon a 6 in. bed of concrete.

188. *The Drains under Walls.*—All drain pipes passing through walls must be protected by a brick arch or stone lintel, to provide against fracture from settlement in the house.

189. *The Cellars and Areas.*—Cellar or area drains should deliver over an external gully; in fact, open channels should be substituted for drains in cellars. These channels can be readily kept clean, whereas with drains the traps frequently remain for long periods without being re-charged and the result is that the water either evaporates or smells badly. Where these channels are made to deliver over an external gully in connexion with a soil drain the water from a sink or bath should be arranged to deliver over the same gully, so that the water in the trap may be frequently renewed. An iron grate should also be fixed in the aperture through which the channel passes, to exclude vermin. It generally suffices to allow the small quantity of water from this source to soak away into the ground a short distance from the house instead of being connected into the drains.

190. *Ventilation.*—Long lengths of drain should always be ventilated at intervals by 3 ft. open chambers having half channel bottoms with iron gratings at the ground level; in fact, the closer a drain approximates to an open channel the better. This is very important where the drain is small, say 4 in. or 6 in., for should such a drain run full bore when badly ventilated there is great resistance from the compression of the air in front of the flow due to friction and also owing to the vacuum created behind the charge, and there exists a strong tendency to syphonage in the traps. The main 6 in. drain from the disconnecting chamber must be ventilated on the outlet side of the trap by a 6 in. branch pipe carried to some convenient part of the building and continued up above the roof, either in a 4 in. lead 8 lb. soil-pipe or in a 5 in. stout iron galvanised pipe with caulked leaded joints.

191. *Iron Ventilating Pipes.*—The use of iron for ventilating pipes, unless galvanised, is not to be recommended, as drain air rapidly rusts and corrodes them. In the case of a drain- or soil-pipe this action does not take place, the greasy constituents in the sewage forming a protecting coat.

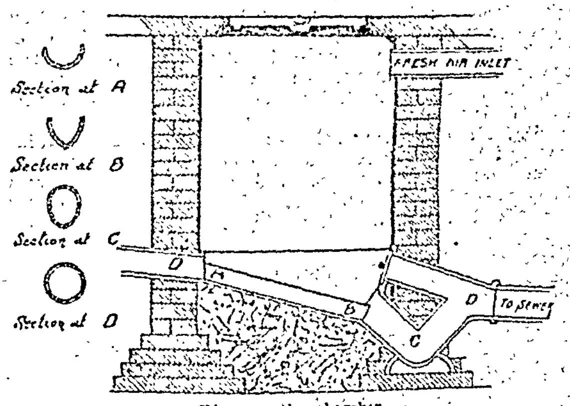
192. *The Surface Water.*—When plans are formed for the treatment of the drainage of a large country mansion an endeavour must be made to reduce as much as possible the quantity of water poured into the soil drain. Apart from the absurdity of needlessly fouling water which has afterwards to be purified the value of the sewage as a manure will be reduced and more land will be required for irrigation. To do this a separate drain must be provided to take the surface drainage from all courtyards, paths, and rain-water overflows round the house and buildings. If possible, avoid crossing these two sets of drains or otherwise bringing them into close proximity, but should it be necessary to cross them the surface water drain must be kept above the soil drain, lest any leakage should occur in the latter at these points and so enter the surface drain.

193. *The Surface-Water Pond.*—Where possible this water should be collected in a pond or reservoir (in this case situated in the kitchen garden); the overflow can be carried into the nearest ditch. A brick disconnecting chamber is to be built at the lower end of the pond, in which is fixed the usual trap and channel, and from which a branch drain is connected into the main drain. A sluice valve or penstock is fitted in the inlet to this chamber. The advantage of this will be fully appreciated not only in the dry season and when it is desirable to give a less concentrated dressing to the land, but also in the winter when the ground is already saturated with moisture. The control of this body of water will also be of advantage for the occasional washing of the storage reservoir of the soil drain.

194. *The Rain-water Drain.*—If the rain-water which falls upon the house is not utilised it must be carried into the surface drain. In any case, even with a cesspool, the surface water must be treated separately. To obviate the necessity of much deep digging it is better to have the highest point of the drain, say, 12 in. below the surface of the ground instead of below the cellar floor. As already mentioned a separate drain should take the waste water from the cellars and areas, carried out in the direction of the slope of the ground and made to deliver over a gully in connexion with the surface water drain or into the nearest natural outlet.

195. *The Soil Drain.*—The soil drain will, of course, be kept entirely outside the house and conducted into a disconnecting chamber (Fig. 21) in the usual way, but in all cases at its extreme end an automatic flush tank should be provided to discharge at least 50 gallons of water every twenty-four hours.

FIG. 21.



Disconnecting chamber.

196. *The Flushing Tanks.*—The flushing tanks must be proportionate in capacity to the length of the drain which they are intended to flush, as, owing to the friction in the small drains now used, in a long drain the initial force of the discharge is soon reduced, the central body of water rapidly passing away in a gradually attenuated stream, while that portion in contact with the pipe slowly follows.

Note P.—In the example given some difficulties present themselves in providing a flushing tank for each head of the two soil drains, terminating as they do at the principal façades of the mansion. Three alternatives offer:—1. To sink the drain some 4 ft. deep in order to allow of flushing-tanks being built below the ground, in which case they might be charged through a disconnecting cistern fixed in one of the outbuildings. 2. By carrying up drains to the higher ground on the north-east corner and there placing the flushing-tanks. 3. By placing the two flushing tanks in the cistern room and bringing down a 2½ in. discharge-pipe from each to deliver over gullies fixed by wall at the head of each drain marked 10 on plan No. 11, the gullies to have large mouths carried up 2 ft. 6 in. above the ground level, with gratings on top. This plan is shown in the example. The waste from sink JJ also discharges into one gully and re-charges the trap, affording an additional protection should the syphon in the cistern fail to act. This precaution, though desirable, is not an absolute necessity.

197. *The Fall of the Main Drain into the Sewage Tank.*—The drain must be laid on a concrete bed at a regular fall throughout. The fall will be regulated by the difference in height between the disconnecting chamber and the sewage tank, which in this case should be capable of holding some 10,000 gallons. If from the nature of the ground it is necessary to make any deviation from a straight line then an inspection chamber must be built at the angle thus made or at any point where a branch drain from the stables or other

buildings may enter it In Rawlinson's "Suggestions" it states that branch drains should have a fall into the main drain at least equal to the difference in their sectional diameter. No branch drain should be connected at right angles with the main drain but should have an inclination in the direction of the fall, with an inspection chamber or eye at *every such junction* Levels must be carefully taken and the trench must be made from end to end before laying the drain, for which purpose the use of sight rails will be found to be very advantageous The main drain should always be first laid and all branches should have a fall at least equal to that of the main drain, if possible a greater velocity should be given in the case of these drains, as it will tend to accelerate in place of retarding the flow at such junctions

198 *The Cultivating Tank* —Just before this main drain enters the cultivating tank (E on plan No 12, also see par 92) another disconnecting chamber must be built with a syphon next to the tank The usual iron cover is to be replaced by an iron grating In addition to this in some isolated spot a long, narrow chamber, 4 ft or 5 ft in length, should be formed in the course of this main drain, the chamber should have a half channel bottom, and the whole be covered with an iron grating This will completely isolate the house from the cultivating tank This tank is made with two chambers, each resting alternately Finally, the effluent passes into a storage or sewage tank F, whence it is passed periodically on to the land either by means of a syphon or pen stock. With the microbe cultivating tank the clear effluent permits of the use of a very much smaller plot of land than would otherwise be allowable The River Pollution Commissioners assume a unit of 2000 persons per acre, but this quantity with crude sewage, unless the soil is in every way favourable, must be considered excessive Where the sewage is in a liquid state from some previous treatment the late Dr Tidy gave from 5000 to 7000 persons per acre Where there is plenty of land available it would be wise to disregard any calculation based upon the above figures and to devote at least an acre of land to every 100 of the population with a due allowance for each animal in the farmyard and stables For the intermittent system the area of land should be divided into a number of compartments, so that the sewage may be allowed to flow on to each part in turn as required If the land devoted to the purpose is on the side of a hill the catch work system is well adapted to the purpose, the water flowing over a succession of made terraces Upon nearly level ground the arrangement shown on the Estate plan No 12 will be found convenient, but in any case the greatest care must be exercised to ensure that the surface over which the water flows is free from all obstruction and that there are no hollows where the sewage can stagnate and spoil the results by the production of rank vegetation The first things to be considered are the subsoil drains (see Estate plan No 12), the depth at which they are laid and their distance apart must depend upon the nature of the soil (see table by Mr Dempsey)

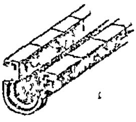
Drainage of Land

Character of soil	Distance of drains apart	Depth of drains
Heavy soils	ft	ft in
Compact tenacious gravelly clay	15	2 6
Stiff adhesive clay	16½	2 6
Friable clay	18	2 9
Free soft clay	21	2 9
Medium soils		
Clayey loam	22	3 0
Marly loam	24	3 0
Gravelly loam	27	3 3
Friable loam	30	3 3
Light soils		
Light gravelly loam	33	3 6
Light marly loam	36	3 9
Light sandy loam	39	4 0
Soft light loam	42	4 0
Sandy soil loam	45	4 0
Light gravelly sand	49½	4 3
Deep gravelly sand	55	4 3
Coarse gravelly sand	60	4 6
Loose gravelly sand	66	4 6

An average depth is about 3 ft 6 in with a distance apart of some 30 ft, and the number of 12 in agricultural drain pipes required varies from about 3000 to the acre in the heaviest soils to about 650 in the lighest The main outlet should be conducted into a reservoir (marked H on plan No 12) in which the effluent water is allowed to subside *before it overflows into the stream which is to receive it* This water, if the irrigation is properly conducted, will be (if not immediately suitable for drinking) very far advanced towards a state of purity

The amount of liquid sewage finally collected is calculated at about 1500 gallons per day, being the maximum probable amount Now each dressing to the land should not be less than about 1 in over the whole surface and this would be equal to 22 622 gallons per acre The plot of about 2¾ acres on the plan is divided into eleven parts of ¼ acre each It will therefore be necessary to collect 6750 gallons, or nearly five days' supply, of sewage effluent in the tank F in order to flood one plot This will allow an interval of a little less than three weeks before it will be necessary to administer a second dressing to any one plot This again will depend upon the number of people in occupation, as a rule the late autumn and winter months are those in which these houses are most fully occupied These being the months during which the ground is most saturated it may be desirable that the amount of land devoted to irrigation should exceed the limit just proposed Of course, the nature of the crop grown on the several plots will determine the question as to how frequently the dressing should be repeated There is a 5 in cast iron pipe carried from the bottom of the storage tank as far as G, where it is fitted with a "Handy-straightway valve" The plots are divided by the main carriers, which are better if fitted with half-round, glazed channel bottoms about 9 in wide (Fig 22) The sides also may, if preferred, be lined with glazed earthenware bricks especially made for the purpose Sluice valves must be fixed at various points in order to divert the stream over each plot as desired or this may be done by simply cutting off the channel by means of a piece of stout sheet iron driven into the earth across the main carriers if these are not lined There are numberless ways in which irrigation can be applied, and the methods will vary according to the situation of the land to be devoted to the purpose Its ready application will frequently tax the ingenuity of the individual adapter, but enough has been said to show that it is a matter of great simplicity and undoubtedly the only way in which all sewage should be disposed of where the water carriage system is adopted With an institution holding a constant resident number of inmates there is less difficulty in regulating the several factors tending to a satisfactory result It is difficult owing to the limited space at disposal to go fully into the varying possibilities of every case, but no insuperable difficulty will be experienced *if the following* points are kept in mind (1) the nature and permeability of the soil, regulating the depth of the subsoil drains; (2) the crops intended to be grown, and (3) the possible amount of sewage and if it is likely to vary to any great extent, together with the probable season of such variation

FIG 22



Main carrier

199 *Drains Under Roads* —Should any drain be laid along or cross under a road precautionary measures must be taken to protect it from damage by heavy traffic

200 *Disconnected Pipes* —All sink and other waste pipes should deliver over half channel pipes before running into gullies

TREATMENT OF BUILDINGS THAT ENVIRON THE MANSION

201 *The Lodges* —Each cottage or lodge to be connected with the system must be treated as a detached house and have a separate disconnecting chamber The bailiff's house and the lower lodge being situated in depressions below the level of the drain outfall, will be treated differently

THE LAUNDRY

202. The drying yard should be turfed throughout and the gullies in the several paths should be connected into the surface drain, for the smaller the area

of ground which is paved the fewer are the opportunities for accumulations of offensive matter. Any foul water falling upon the living earth such as grass land is at once purified, but the same falling upon a paved surface escapes through fissures, under more or less pressure, to the earth below and has to depend entirely upon mechanical action to restore its purity. There need be no drains within the laundry but channels should be provided in order that the floor may be kept thoroughly dry. Square fireclay tubs are considered to be the most satisfactory in every way, but as they absorb a large amount of heat from the water in the first instance there must be a very efficient supply of hot water. External gullies must be provided to take the wastes from these tubs, the drain from which discharges into a disconnecting chamber. A closet is to be formed and fitted in this laundry in all respects the same as closet EE in the mansion but with a white glazed trap, and a separate drain from this closet is connected into chamber having a 3½ in. 10 lb. lead ventilating pipe carried up above the highest point of the roof and clear of all windows. The laundry is divided from the stables by a 14 in. brick wall which runs longitudinally through the building, the rooms on the first-floor being used for drying and ironing. The rain-water falling on these buildings, which cover a considerable area, is collected in the main rain-water tank after passing through a filter. (See Fig. 1.) Provide and fix a 300-gallon galvanised iron cistern in the first floor with overflow through external wall, carry down a ¾ in. warning-pipe to pump.

Note Q.—In cisterns charged by pumps a "warning-pipe" is commonly fixed. It consists of a small pipe connected into the cistern just below the level to which the cistern is to be filled, the other end of the pipe terminating close to the operator at the pump. The operator watches the end of the pipe and the first sign of water escaping warns him to desist from pumping.

Provide and carry to this cistern a 1½ in. galvanised iron rising main from pump. Soft water acts very readily upon lead and iron pipes, so that either galvanised iron or copper tubes must be used for the hot-water circulation to the tubs, copper being the best, as there is always a certain amount of risk of iron-mould to the clothes where iron is used for hot water, even if it is galvanised. (See pars. 10 and 44.)

A copper dome-top boiler is to be set in brickwork with 1 in. copper flow and return pipes carried round the walls of the laundry to a small copper supply cistern which is fixed at the extreme end of the circulation. From the flow-pipe short supply-pipes are brought down to the tubs, these pipes being fitted with horizontal bib-valves. Provide and fix a dead-weight safety-valve to the boiler. Lay on a ¾ in. block-tin or copper pipe for supply to feed the cistern from the cold soft-water cistern. Carry a similar cold 1 in. service-pipe from the same cistern to supply each of the tubs. Carry to this soft-water cistern a ¾ in. lead supply-pipe from the main in the road fitted with a ¾ in. high-pressure ball-valve and screw-down stopcock as a supplemental supply. In addition to the above a ¾ in. short branch pipe is brought off the main and is carried to one of the tubs, being fitted with a screw-down bibcock and having a ¾-in. screw-down stopcock fixed in the service-pipe just above the draw off.

THE STABLES.

203. The stables should be drained with cast-iron channels and covers made to deliver into the open air over a gully. The drains from the water-closets, sinks, gully, &c., will be made to meet in a disconnecting chamber and will be ventilated in the usual way, together with the upper end of the main branch from the sewage tank.

GARDENER'S LODGE No. 5.

204. *Recommendations with regard to the Gardener's Lodge, No. 5.*—The existing open midden in the garden is to be cleared away and filled in with dry ground. Build upon a proper footing in 9 in. brickwork a lean-to building to form a new water-closet, 4 ft. 6 in. by 3 ft., the inside measurement being at the lowest point 7 ft. 6 in. high. Provide a window in the end, fitted with a casement sash measuring 3 ft. by 2 ft. glazed with obscured glass. Provide a ledge door and frame, 6 ft. 6 in. by 2 ft. 6 in., with an oak sill. Form a lean-to roof covered with slates. Form a Portland cement floor laid on a 3 in. concrete bottom. Provide and fix a short flushing rim hopper closet and carry a 4 in. stoneware pipe drain into the disconnecting chamber. Supply and fix a properly hung deal seat. Twice limewhite the closet walls. Supply and fix upon suitable brackets a 3-gallon galvanised iron flushing tank and lay on a ½ in. stout lead branch service-pipe from the slate cistern in the scullery, this being fitted with a ½ in. ball-valve. Continue the short overflow-pipe through the external wall. Lay on a supply to the arm of the closet with a 1½ in. lead service-pipe, properly fixed with cast-lead tacks, from the flushing cistern.

205. *Sink and Supply to same.*—There is a stone sink in the scullery with a brick drain under it leading into the ditch on the other side of the road. A slate cistern (100 gallons) is fixed in the scullery to supply this sink. There is no overflow-pipe, but a warning-pipe (see Note Q.) is carried to a pump fixed over a deep well. This pump is worked by horse power and supplies water for the gardens and farm buildings, being taken to the two last in a water-cart.

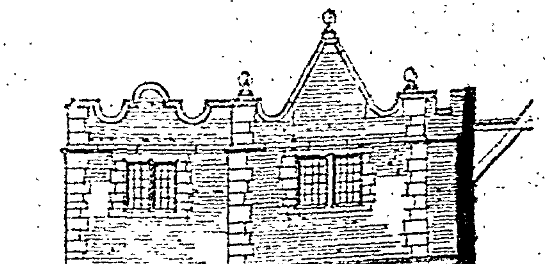
206. *Recommendations.*—Replace the old stone sink by one of glazed stoneware. Provide and fix a 1¼ in. lead syphon trap under it (see Fig. 18) and carry the waste-pipe through the external wall to deliver over a new gully. Disconnect the present supply from the pump and connect into the nearest point of the new main in road a ¾ in. stout galvanised iron service-pipe fitted with a ¾ in. equilibrium ball-valve. Remove the warning pipe and instead carry a 1¼ in. overflow-pipe through the external wall.

THE BAILIFF'S HOUSE.

207. The bailiff's house (No. 6 on plan No. 12) is of much earlier date than the mansion, and is situated in a hollow; the whole of the drainage will have to be dealt with locally; the system adopted will be that recommended by Dr. Poore, which can here be well exemplified.

208. *The Present Arrangements of the Bailiff's House.*—The water-supply is from a well about 60 ft. deep, which is fitted with a windlass and buckets. There are two midden-closets in the garden which are built over a ditch which is dry excepting in times of heavy rain. The sink in the scullery has a short lead waste-pipe connecting into a brick drain, which is carried into a cesspool in the garden. A pan closet on the first-floor landing is connected into cesspool by a 4 in. iron rain-water pipe. The cistern over closet is charged by rain-water from valley gutter of roof with a 3 in. zinc standing waste carried into side of D-trap of closet. There is a supplemental supply to charge this cistern from the pump in scullery. There is a short system of brick drains under the kitchen wing which take water from the brick floors and yard gullies, eventually delivering into the ditch. There is thus an easy communication for rats to the interior of the house.

FIG. 23.



209. *Recommendations.*—The water-closets, bath waste water, and bedroom slops are treated separately, as also is the waste water from the sinks. The present closet in the house, which is connected into the cesspool in the

garden, is to be entirely removed and the walls of the cesspool are to be broken down, the whole being cleared away and the opening filled in with earth. A small annexe is to be built, as shown (Figs. 23 and 24), connected with the main building by a short corridor provided with cross ventilation. The upper portion (Fig. 25) consists of a bathroom and closet with sink, whilst below (Fig. 26) is another closet for the use of the domestics, access being had to the same through the arch supporting the corridor which thoroughfare is thus protected from wet. The illustrations, which are adapted from those in Dr. Poore's book upon Rural Hygiene, will clearly indicate the details. The points to be particularly noticed are the cross ventilation of the lobby to the closet and also of the capacious dry catch; the ventilation of this last is effected by the iron gratings in the wall and by the brick flue at the back of closet (see Fig. 9). The seat of the closet is only 14 in. above the floor line in place of the usual 18 in. This is a very important point, as when the closet is used the dejecta fall perpendicularly instead of being thrown against the pan There are also certain physiological advantages from the position assumed by the user of the lower seat which are absent in the other.

FIG 24.*

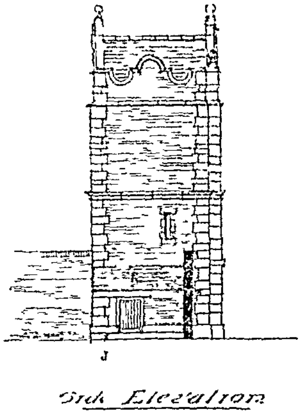


FIG 25.

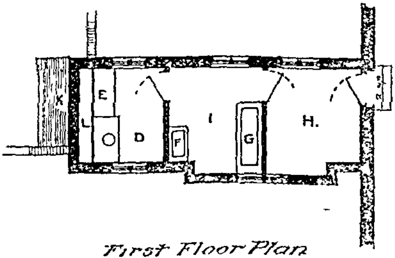
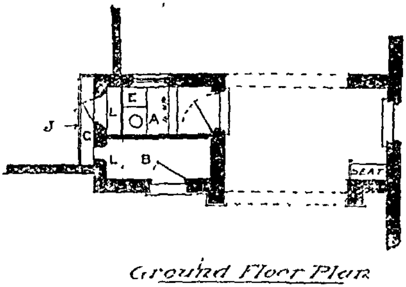


D, Closet. E, Earth box F, Sink G, Bath. H, Lobby with cross ventilation I, Bathroom K, Lean-to roof to exclude rain from C L, Ventilating shaft open at roof

The pan, which may be constructed either of earthenware or metal, is provided with a straight back and is fitted with a flap-valve which is so adjusted by a counterbalance weight that it permits the excreta and earth to fall at once into the catch below, at the same time excluding any up draught (see Fig. 27). The floor of the catch is cemented and the door to it has a space at the bottom of some 4 in., which is filled with fine wire netting, so that air may freely enter and all small animals may be excluded. One or two shovelfuls of dry "living" earth taken from the surface of the ground are thrown on the floor after each removal of the contents of the catch. (Earth taken from below the surface is dead and exerts no humifying influence.)

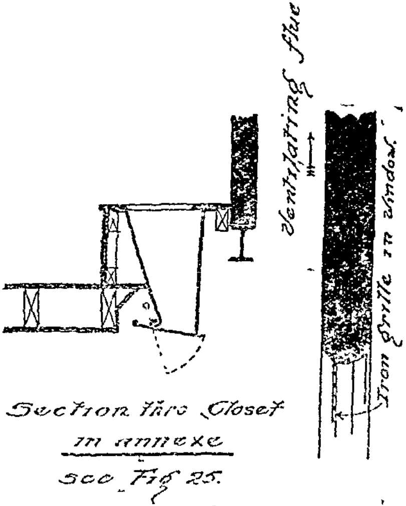
FIG 26



A. Closet for domestics B. Dry catch of upper closet. C, Gutter for urine. E, Earth box J, Dwarf wall round C to exclude surface water L, Ventilating shaft open at roof, sides, and end provided with air spaces

The dry catch has many advantages over the pail system. In the first place, if from any cause the closet should not receive the usual daily attention no evil will result even though it be left for a week, whereas with the pail not only does it become full, but owing to urine being unable to escape and evaporate, it soon becomes offensive. The condition into which these pails have been permitted to fall owing to neglect has in a large measure brought the earth-closet into such bad odour. The large pails used in some places where the so-called dry system is in vogue are at the end of the week in a condition to poison anyone who is unfortunate

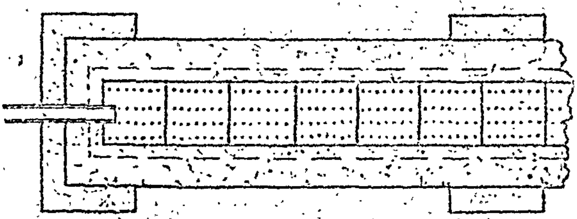
FIG. 27.



enough to come within a yard of one of them. Where the closets are used extensively for micturition a trough must be formed, as shown in Fig. 26, into which the urine will drain. This trough must be filled with sawdust or earth and will only require to be emptied at intervals, varying, of course, with the number using the closet. It is important that rain-water should be excluded. The other midden closets in the garden are to be converted into dry-catch closets.

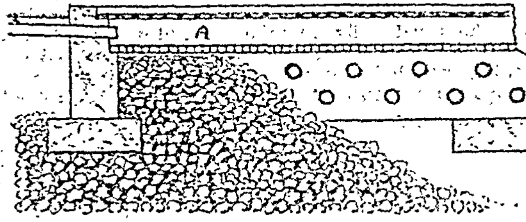
210. *The Bath.*—A short 2 in. lead waste-pipe is to be carried through the external wall, properly trapped and ventilated by a 1½ in. anti-syphonage pipe carried through external wall (see Fig. 18), to deliver over a 2 in. galvanised cast-iron rain-water head the pipe from which is carried on across the arch and down to deliver into a half-round channel gutter which crosses the stable-yard and empties over an evaporating trench or filtration gutter to be described (see Figs. 28, 29, and 30). Dr. Poore objects to the use of any trap under either a bath or sink as forming a receptacle for the development of putrefactive organisms, but it is doubtful if the absence of this trap compensates for the foul air that is then frequently drawn into a room through the waste-pipe in which the fatty matter from the soap accumulates and decomposes, though by keeping this pipe thoroughly ventilated much of this is avoided.

FIG. 28.



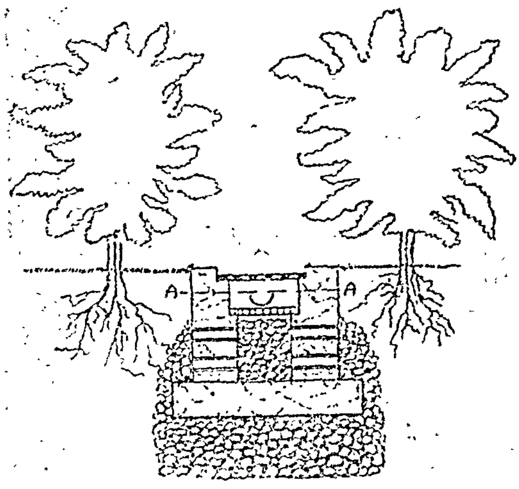
Plan.

FIG. 29.



Longitudinal Section.

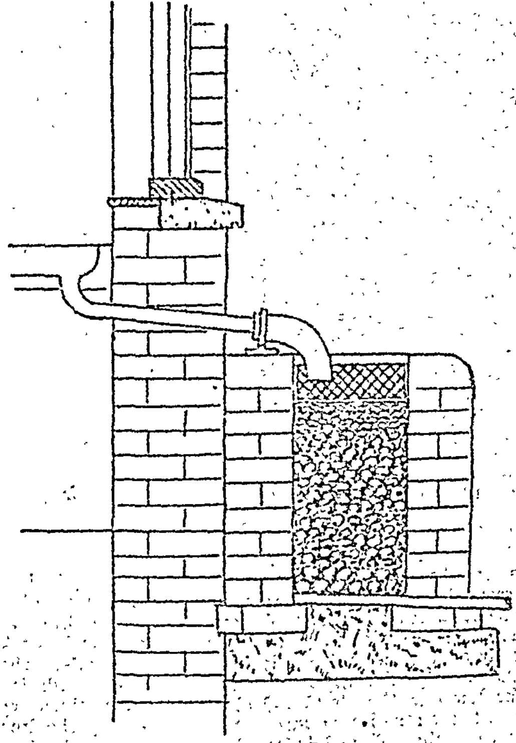
FIG. 30.



Transverse Section.

211. *The Filtration Gutter.*—To receive the slop waste water a trench should be formed on the other side of the stable-yard 15 ft. long, 2 ft. 6 in. wide and 2 ft. deep, the sides being lined with 9 in. dry brickwork or formed in concrete pierced with 2 in. agricultural pipes. This trench is filled to a height of some 12 in. with small stones, which offer a large evaporating surface. The stones may be covered with perforated tiles which permit some of the water discharged upon the surface to flow on and gradually become absorbed. A hedge is planted on either side of the trench which also helps to absorb and evaporate the moisture. If desired the trench may be covered by an open iron grating.

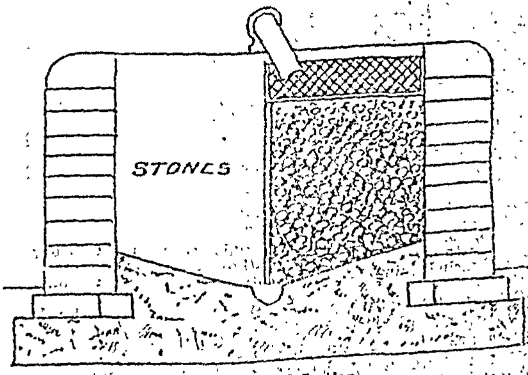
FIG. 31.



Transverse Section.

212. *A Slop Sink* properly trapped and fitted with anti-syphonage pipe is to be provided on the first-floor for the reception of the bedroom slops. The waste-pipe from this sink delivers over an open half-round channel which ultimately connects into the evaporating trench. It is of course unnecessary to insist that the joints of these channels should be watertight excepting those immediately surrounding the house.

FIG. 32.



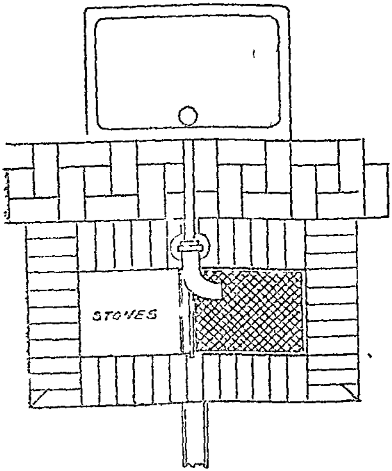
Longitudinal Section.

213. *The Scullery Sink* is treated somewhat differently, in order to keep the discharge from the waste pipe above the ground level it may be necessary to form a raised platform by means of which the sink may be kept up an additional 14 in or 16 in (Fig 31) The waste pipe from this sink discharges over a brick built chamber filled with small stones. This chamber measures about 3 ft 3 in by 1 ft 3 in by 2 ft deep and is divided in the centre by a 1 in slate division; the bottom and the sides of the two compartments thus formed are rendered in Portland cement There is an outlet from each of these compartments into an open channel which is connected with the main system (Fig 32) The actual waste pipe from the sink is fitted with a swing nozzle which permits the discharge to be directed into each of the divisions of the chamber every alternate week, the water from the sink passing first through a wire straining dish, which arrests tea leaves, potato peelings, or any other solid refuse which it is necessary to exclude (Fig 33) The stones in the compartment at rest have to be lifted out and exposed to the air and sun about once a month for one or two days, but they do not require any other attention This system of dealing with a scullery sink waste water has been found to answer admirably in a small establishment but its suitability for a large house or hotel discharging daily large quantities of fat and sand would be open to question unless provision were made to arrest the deposit It is unnecessary to detail the plumber's work in connexion with the water supply which is brought from the main supply to the hydrant situated at the corner of the farm buildings

FARM BUILDINGS

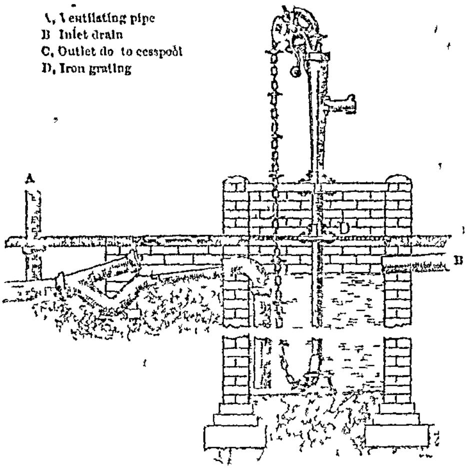
214 The farmyard, or more correctly the stockyard, presents some difficulty to the sanitarian in order to comply with the accepted practice and the requirements of the agriculturist. It is desired that the manure may be trodden by the stock into the straw laid down and the whole mass be intimately mixed This produces a form of manure the effect of which when it is spread upon the land is more readily apparent than is the case where it is used prior to its assuming this rotten condition. It is, however, open to question whether the land receives the permanent benefit that would accrue to it if this manure was placed on it in a less advanced stage of decomposition That the air emanating from these festering heaps is detrimental to the health of the cattle which winter on them cannot be questioned The ground beneath is sodden with moisture and has no period of rest in which aeration might restore it to a condition capable of assisting nitrification, one result being that a large quantity of valuable liquid manure is not only lost but leaks away through the lower stratum of the soil with the chance of polluting any adjacent wells or streams to which it must eventually gain access

FIG 33



Plan

FIG 34



A, Ventilating pipe
B Inlet drain
C, Outlet do to cesspool
D, Iron grating

Manure tank

Milch cows may often be seen standing knee deep in this liquid mess with their udders fouled by the filth, a condition of things by no means pleasant to contemplate The floor of the farmyard, piggeries, and cow stalls should be formed of some impervious material, such as brick, asphalt, or concrete and cement Channels must be made to conduct the surface drainage into a manure tank (see Fig 34) in the yard This tank must not be of a large size, but should hold about 500 gallons and should be fitted with a chain pump so that the contents can be occasionally discharged over the manure in the yard to increase its value or into a cart for use elsewhere This tank must have the sides carried up above the level of the surrounding straw and must be covered by an open iron grate A 6 in overflow-pipe like an inverted syphon from the bottom of this tank is to be carried into the main drain, with a syphon trap fixed close to the manure tank, as illustrated, and a 5 in galvanised iron ventilating pipe is to be carried up from the end of the drain as before described The animals must, of course, be provided with open sheds in which to obtain shelter, but the practice of roofing over the whole of the stockyard in order to exclude rain is not much to be commended as it is apt to confine the emanations from the manure, nor is it necessary where the yard has an impervious bottom and is properly drained The straw yard cannot be looked upon with favour from a sanitary point of view Dr Poore, in his book upon Rural Hygiene, says that the farmer who buries his organic manure *directly it is produced* will lose nothing by waste It will not give off ammonia to the air nor will the juices be washed away by rain to the same extent as when it is left above ground to be a nuisance There seems to be no doubt whatever that all heaps of manurial matter which give off ammonia and other gases to poison the air and perhaps do more serious mischief are allowing valuable matter to escape which ought to be undergoing oxidation in the earth. In fact, for the agriculturist stink means waste. The reasons why farmers allow putrescible matter to fester in heaps appear to be (1) that it has to be kept till the land is clear and circumstances permit of its being dragged to the fields; and (2) that when the matter is thoroughly rotten and most offensive *a more rapid and visible* result is produced, notwithstanding that the total result is probably less than if it had been applied to the ground at once. It is certain that putrescible matter intended for manure must waste more above ground than when buried immediately beneath it.

THE LOWER LODGE NO. 8.

215. The lower lodge No. 8 presents a striking example of the evils of cesspool drainage owing to the water-logged condition of the ground.

216. *Closet.*—There is a water-closet in the back addition which drains into a cemented cesspool, also receiving the waste water from the scullery sink and the rain-water from the roof. The cistern supplying the water-closet is fixed in the scullery, the sink in which is also supplied from the same source. This cistern is filled by means of a pump in the scullery which draws its supply from the shallow well in the garden. The pump is defective and the barrel is too large for the existing suction pipe.

217. *Recommendations.*—The closet, the cistern, and the pump will be entirely removed together with the stone sink. The closet, which is a small lean-to building next to the scullery, will be cemented throughout, including the floor, with Portland cement after the removal of the seat and the present wood floor, and a door fitted in the back wall of the closet under the new seat, which last is raised upon two brick steps and the whole finished as described for the servants' closet AA and BB (par. 144), with the exception of lining walls with tiles.

218. *Cesspool.*—No provision is made for any overflow from this cesspool as there is no place other than the stream into which such an overflow could be carried. The result of this is that the liquid contents escape into the surrounding ground, which is already saturated with moisture. During heavy storms the evil is, of course, more pronounced, the contents of the cesspool overflowing at the top on to the surface. Were it not that the well is favourably situated above instead of below the cesspool—that is, in the opposite direction to the flow of the subsoil water—very serious pollution must have ensued (see par. 31, Fig. 2).

219. *Recommendations.*—The contents of the cesspool must be entirely removed and the brickwork broken up and carted away, the hole being filled in with fresh earth.

220. *The Well.*—Owing to the isolated position of this lodge the water-supply will be taken from a shallow well about 12 ft. deep already existing, but it must be lined with tubes, as described in par. 33, the upper one standing up 18 in. above the ground level. The bottom of this well is to have a 12 in. layer of clean flints or rough stones; on the top of these stones about 6 in. of coarse gravel are placed, then come another 6 in. of fine gravel and 2 ft. of well-washed sharp sand, and, lastly, a few inches of fine gravel are laid to prevent any displacement of the sand by the action of the pump. The normal level of the subsoil water at this point being not more than about 3 ft. below the surface there will always be about 5 ft. of water in the well. Carry upon 4 in. of Portland cement concrete round the outside of the upper tube forming the well 9 in. of brickwork in cement, finished with a course of brick on the edge. Provide a circular wood cover to the top of the well, fitted with iron handles for lifting, and covered with 5 lb. sheet lead dressed down 3 in. all round the rim. The under side of the cover touching the top of the inner well tube is to be packed with a layer of asbestos sheeting so that it may fit closely and prevent the entrance of insects to the well. As the lodge occupies slightly rising ground on the north side of the valley which is drained by the stream and the lake and towards which the subsoil water *flows*, there is no danger of pollution to the shallow well, the soakage being away from it, whilst the depth of the well will not permit the water to be lowered so as to influence the drainage area in the neighbourhood of the soakage trench.

221. *Pump.*—Provide and fix in the scullery a 2½ in. barrel pump, carry a 2 in. stout lead suction-pipe from the same to the bottom of the new well, this pipe being laid in an open-jointed, tile-covered brick channel. This suction-pipe, just where it enters the well, is to be fitted with a lead collar so as to throw off any water that may have run back on the outside of the pipe. *Care must be taken that the hole* through which it enters the well is made quite sound so as to exclude any surface water.

222. *Sink.*—Provide and fix in the scullery an earthenware enamelled sink 2 ft. 6 in. by 1 ft. 8 in. with a 1¼ in. lead trap under the same. Carry the 1¼ in. lead waste-pipe through the external wall so as to deliver into an open channel-drain and provide the usual 1¼ in. anti-syphonage pipe.

223. *Slop-sink.*—In the external corner by the scullery door form on a concrete bed an enclosure constructed with blue Staffordshire bricks laid in cement, measuring 18 in. by 18 in. and 12 in. high, built in 4½ in. work and finished with half-round bricks on edge on the top, with the interior sloping into a half-channel bottom. Continue this channel to connect with that from the sink. This enclosure is to form a receptacle for the bedroom slops, which must not be thrown into the scullery sink. If the rain-water is not to be utilised the rain-water pipes can deliver into open channels connected with those already mentioned. The outlets from these channels are to be carried in a direction opposite to the well and are to be turned into a filtration gutter some 10 ft. long (see par. 211). By the side of which gutter a hedge is to be planted which will be found to assist evaporation greatly.

PRINTED and PUBLISHED by the REGISTERED PROPRIETORS at No. 423, Strand, W.C., and Nos. 1 and 2, Bedford-street, adjoining.

at present holds, and when we reflect on the extremely unsatisfactory nature of our conceptions of the things which we name atoms and molecules and of the forces by which they are affected, and also on the wonderful variety in composition in structure and function of living animals, the physiologist may bear with equanimity the gibe cast upon him by the physicist and the mathematician that his subject has not yet risen to the rank of a science Professor Verworn, after giving a short but excellent history of physiology, discusses the question of vitalism and a vital force Are the phenomena which present themselves to our observation in living beings, he inquires, the effects of known forces, as chemical affinity, light, heat, and electricity acting on the atoms of matter, or do they require for their explanation the admission of a "vital" force differing from, though perhaps correlated with, those forces? The idea is an old one and has been often controverted but as often reappears; it is admitted indeed that many of the phenomena are explicable upon physical and chemical principles, but there still remain many phenomena which at present apparently call for other principles and seem to follow other laws Consciousness, for example, cannot be explained by what we at present know either of chemistry or of physics, nor are we as yet sufficiently advanced to express in symbols the exact composition of a living cell and we recognise only with difficulty the difference between dead and living protoplasm, we recognise it indeed not by any difference in its chemical or physical characters but, as Pflüger pointed out, by the fact that "the atoms of the dead proteid molecule are in a condition of stable equilibrium, while the living proteid molecule possesses a very labile constitution" As might be expected in a work on general physiology, protoplasm, or living substance, its forms, activities, and attributes, are given in great detail Here and there, indeed, statements are made which require some modification, as in the remark that in the tissues "every individual protoplasmic territory which belongs to a nucleus is sharply separated from all the rest," whereas it might be more correctly maintained that in many cases each cell is by means of protoplasmic processes both in animals and plants in direct continuity with the rest Protoplasm the author holds to be a fluid and he gives one more to the already numerous definitions of life—viz, that it consists in the metabolism of proteids.

The Phenomena of Motion are grouped together and treated in a very interesting manner by Professor Verworn He begins with the consideration of Brownian movement which he regards as of a passive nature and due to the constant slight impulses of the molecules of the surrounding liquid upon the small light bodies suspended in it This is followed by an account of the movements caused by swelling of cell walls, as is seen in the resurrection plant (Selaginella lepidophylla), the rose of Jericho, the seeds of the cranesbill, and the elaters on the spores of the horsetail He goes on to describe the movements due to changes in cell turgor consequent on osmosis which are to be seen in many plants, then come movements from change of the specific gravity of the cell, as in numerous low forms of pelagic life which seem to have the power of suddenly eliminating a tiny bubble of carbonic acid gas; then there are the movements associated with secretion, as in the desmid Closterium which discharges a slimy substance from one extremity of its body by the aid of which it creeps or glides; then come the movements due to growth as in the seeds of the impatiens, and, finally, there are the movements effected by contraction and expansion of the cell body, including amœboid, ciliary, and muscular movements, to which Professor Verworn has, it is well known, devoted much attention He also, although under a different heading—namely, that of Stimuli and Their *Actions*—gives an interesting account of the effects of long-continued stimulation upon the microscopic appearances of muscle and nerve, illustrating these effects by references to the observations of H. M Bernard on bluebottle flies, some of which were allowed to remain at rest, whilst others were stimulated till they were exhausted, and those of Hodge on the ganglion cells of the sparrow as they appear in the morning and at night.

Many of the subjects discussed are either altogether passed over, or are only noticed in the most cursory manner, in the ordinary text-books, such, for example, as the Origin of Life, the Question of Physical Immortality, and the History of Death. In regard to the origin of life the author considers in detail the doctrine of spontaneous generation, the theory of Cosmozoa which holds that the first life on the planet was brought by meteorites, removing the difficulty backwards by one step only, for the question immediately arises, How did it make its appearance in them? the hypothesis of Preyer to the effect that the idea of living substance having been at some time derived from lifeless substance may possibly be a false assumption and that the question to be asked is rather, Has lifeless originated from living substance? In contrast, therefore, to the doctrine of spontaneous generation Preyer puts forward the idea that living substance is the primary thing and that lifeless substance is derived from it secondarily by excretion "Whoever," Preyer says, "interrupts the *series of successive* generations of organisms by the introduction of a generation without previous parentage is arbitrary. *Omne vivum e vivo* is a proposition which has never experienced an exception" These views are, however, more or less fanciful and scarcely commend themselves to common sense Professor Verworn himself seems to favour the more suggestive utterances of Pflüger, who contends that the beginning of life is in remote times and is to be looked for in the formation of cyanogen For belief in this he points out there are numerous reasons In the first place cyanogen and its compounds, such as potassium and ammonium cyanide, hydrocyanic acid, cyanic acid, &c, arise only in an incandescent heat Then cyanogen is a radical possessing a great quantity of internal energy. Cyanic acid, a product of the oxidation of cyanogen HONO, possesses great similarity to living proteid. Both cyanic acid and living substance grow by polymerisation, by *chemically combining* similar molecules like *chains into masses.* Both bodies in the presence of water are spontaneously decomposed into carbonic acid and ammonia "Both afford urea by dissociation; that is, by intra molecular rearrangement, not by direct oxidation Finally, both are liquid and transparent at low temperatures and coagulate at higher ones, cyanic acid earlier, living proteid later." This similarly is so great that cyanic acid may be termed a half living molecule Pflüger observes. "When we think of the beginning of organic life we must not think primarily of carbonic acid and ammonia, for they are the end of life and not the beginning." In concluding our remarks here we do so not because there are not many topics of interest to which attention might be directed but because our space is limited and we should like our readers to read the book for themselves and from it they will, we are sure, derive both pleasure and instruction

---

A Clinical Text book of Medical Diagnosis for Physicians and Students By OSWALD VIERORDT, M D, Professor of Medicine at the University of Heidelberg Authorised Translation, with Additions by F. H. STUART, M D. Fourth American Edition from the fifth German With 194 Illustrations London The Rebman Publishing Company 1898 Pp 603 Price 24s

THE earlier editions of this work are probably known to many of our readers. The fact that five editions have been called for in nine years is sufficient proof that the efforts of the author have met with the success which they deserved Dr. Vierordt is remarkable for his powers of observation and the facility with which he places his conclusions in the form of words. The present volume is replete with numerous valuable facts and suggestions to aid the student and the medical practitioner in the examination of patients.

Every part of each subject is dealt with in the greatest detail. The introductory remarks on taking the history of the case, for instance, show the thoroughness with which every point has been considered. The conclusions which may be arrived at from a "general examination" of the patient are also well given, especially the remarks on the varying conditions of "the skin and subcutaneous cellular tissue."

The author writes with particular clearness on the Examination of the Respiratory Apparatus. It is very difficult to express in words the pathological sounds and signs which are encountered in percussing and auscultating the chest, but a careful study of Dr. Vierordt's remarks will greatly aid the student in understanding the alterations from the normal in both methods of procedure. No book can, indeed, take the place of practical instruction in percussion and auscultation, but at the outset of his medical studies the student frequently becomes confused owing to the numerous new terms with which he is confronted and needs some book such as the one now under consideration to help him to fully understand what he has heard from his instructors at the hospital. Unfortunately the nomenclature of physical signs is by no means determined, the numerous synonyms being differently employed by physicians. It is to be regretted that the report issued by the members of the committee appointed at the International Congress of London in 1881 to draw up a uniform nomenclature of physical signs in the diagnosis of diseases of the chest has not been more generally adopted.

The chapter on the Examination of the Circulatory Apparatus contains a vast amount of information; the description of the variations in the rhythm and character of the heart sounds is facilitated by some simple diagrams. The examination of the blood is particularly well described and a mass of detail, interesting to an expert but of little value to the practitioner, has been wisely omitted, but sufficient is inserted to enable the student to make a full investigation of the blood in the various forms of anæmia and to recognise the malaria parasites.

The modern requirements of the examination of the digestive apparatus are met by full directions as to the chemical and microscopical analysis of the digestive juices. Great stress is laid by some observers on the importance of such examinations, more particularly the chemical. Considerable discomfort is thereby caused to the patient, but it is open to doubt whether the more exact knowledge which is claimed to be thus acquired will materially alter the treatment hitherto adopted after an ordinary examination of the patient with due attention to the clinical history. We believe we are correct in saying that the use of test meals and the frequent passing of the stomach tube required for the purpose have not found much favour in this country.

The chapter on the Examination of the Urinary Apparatus is also marked by the judgment exercised on the selection of the chemical processes required. Only a few tests are given for the detection of albumin and sugar but they are the most reliable and they can confidently be employed in general clinical work.

We consider that the directions for the examination of the nervous system form one of the best chapters in the book, especially that part of it which deals with electrical tests. This subject is a very difficult one for students to grasp, but the author explains in clear terms what should be observed in determining the electrical reaction, especial stress being naturally laid on the reaction of degeneration and the myotonic reaction. In future editions we would suggest to the author that he should enter into rather more detail as to the existence or absence of the knee-jerk, pointing out the diagnostic knowledge thereby attained in differentiating between organic and functional diseases. The book is well produced, the type, illustrations, and binding being everything that could be desired.

Manual of the Diseases of Children. By JOHN MADISON TAYLOR, A.M., M.D., Professor of Diseases of Children, Philadelphia Polyclinic; and WILLIAM H. WELLS, M.D., adjunct Professor of Obstetrics and Diseases of Infancy in the Philadelphia Polyclinic. London: H. Kimpton. 1899. Pp. 720.

THE authors tell us that their aim in writing the book has been "to present in a clear and concise manner the chief points in the description, differentiation, and treatment of diseases of children" and they have carried this out most successfully. They have kept to their text—Diseases of Children—and have not padded their book out by unnecessary descriptions of adult types of disease—a temptation to which writers on the subject are very apt to succumb.

There are excellent accounts of the growth of infants and of their various organs followed by a very clear exposition of the principles of infant feeding. Where artificial feeding is necessary the authors follow Rotch in their recommendations and give full instructions for the modification of cow's milk, so that any desired percentage of proteids, carbohydrates, and fats can be obtained. The section on Diseases of the Alimentary Canal, so important in the first two years of life, is full of sound teaching and apt hints on treatment. It is the best section in the book. In America tuberculous peritonitis, if the statements in the book are correct, appears to be much less amenable to medical treatment than it is in this country.

A word of praise must also be given to the section on the Exanthemata, which gives briefly but very clearly the essential points in connexion with the diagnosis and clinical course of infectious diseases of children. The book concludes with practical directions as to diseases and accidents requiring surgical procedures.

We can heartily congratulate the authors on their work. Although containing little that is novel it is so well arranged, clearly written, and devoid of padding as to form one of the best books for the use of the student and the practitioner.

The Throat and Nose and their Diseases. With 550 Illustrations in Colour, mostly designed and executed by the author, LENNOX BROWNE, F.R.C.S. Edin., Senior Surgeon to the Central London Throat, Nose, and Ear Hospital; with special assistance as follows:—Anatomy: MAYO COLLIER, M.S. Lond., F.R.C.S. Eng.; Nervous Diseases: JAMES CAGNEY, M.D. R.U.I.; and Histopathology: WYATT WINGRAVE, M.R.C.S. Eng., Assistant Surgeon and Pathologist to the Central London Throat, Nose, and Ear Hospital. Fifth edition, revised and rewritten. London: Baillière, Tindall, and Cox. 1899. Large 8vo. Pp. xxxii and 968. Price 31*s.* 6*d.* net.

IT might be thought that little need be said on the appearance of a fifth edition of a work which first saw the light more than 21 years ago, but there are several features in the present issue which certainly deserve to be mentioned. The book itself has grown in volume in spite of the expenditure of much care to keep it within its former dimensions. One feature of this edition is the presence of "special assistance" from various writers on certain subjects. Thus the chapters on the Anatomy of the Nose, of the Pharynx and Fauces, and of the Larynx have been revised by Mr. Mayo Collier; the chapter on the Nervous Diseases of the Larynx has been written by the late Dr. James Cagney; and the sections on the Normal and Pathological Histology have been contributed by Mr. Wyatt Wingrave. These are useful additions and materially increase the value of the work. The whole work has been carefully revised and is fully abreast of the knowledge of to day There are 417 illustrations in the text and these are all printed in coloured ink; this is distinctly an advantage in the diagrams representing microscopic sections, as a clearer idea is given of the object, but we fail to see the utility of the colouration in the diagrams, which only represent instruments There are 15 coloured plates representing chiefly diseases of the pharynx and larynx These are hinged and can be opened out so as to lie beside the book during the perusal of the whole of the chapter descriptive of the disease illustrated These and the other illustrations are deserving of praise

Analytical Records

FROM

THE LANCET LABORATORY.

CARBOLIC ACID SOLOID

(BURROUGHS WELLCOME, AND CO; SNOW-HILL-BUILDINGS, E.C)

PURE carbolic acid is ever in request and any method therefore which adds to its more convenient use in practice is acceptable Such is the aim of the carbolic acid soloid containing 60 grains of the pure crystalline acid With a stock of these the practitioner can readily prepare antiseptic solutions of definite strengths Moreover, this stock may be carried in the smallest possible bulk The carbolic acid soloids are of about the size of a shilling and about a third of an inch thick They are quite distinctive in shape and colour, while when dissolved in water they yield a bright green fluorescent fluid, the fluorescent colour being characteristic of uranine These steps are taken in order to avoid the possibility of a mistake being made Carbolic acid soloids are also to be obtained which contain 20 grains of the pure acid

JOHANNIS NATURAL MINERAL WATER (LITHIATED)

(THE APOLLINARIS CO LTD 4 STRATFORD PLACE, OXFORD-STREET W)

Johannis water contains naturally, according to our own analysis, traces of lithium salts but hardly to any important amount medicinally The well known solvent action of lithia on uric acid has prompted the idea of adding, as is stated one grain of lithium bicarbonate to each pint bottle of Johannis water We agree that a natural mineral water is a good method of administering lithium salts but we do not think that such a small quantity as one grain per pint is likely to afford any special benefit. According to our analysis, the quantity of bicarbonate of lithium added was 0 98 grain per bottle The B P dose of the normal carbonate is from three to six grains in three or four ounces of aerated water This is equivalent to from five and a half grains to 11 grains of the bicarbonate

NEW VINOLIA PREPARATIONS

(VINOLIA CO LTD MALDEN-CRESCENT N)

We have always found on analysis of the Vinolia preparations a plain indication of the choice of the purest materials in their elaboration The preparations before us show no breach of this rule Losaria Peau d'Espagne Soap for example, was found to be absolutely free from alkaline excess and from other injurious constituents It is very delicately perfumed and contains the highest possible proportion of pure soap The shaving soap submitted showed similar results Preparations which we also examined with equally satisfactory results were smelling salts Fuller's earth toilet scent known as 'Liril,' Violette de Parme and toilet powders The latter possess the very desirable quality of a powder intended for application to the skin—namely, a highly comminuted state They contain a mild antiseptic

HAY'S INVALID FRUMENTINE

(HAY'S FLOUR MILLS GROSVENOR STREET HULL.)

As we have previously pointed out, this food is prepared on correct dietetic lines, since care is taken in its preparation not to eliminate valuable food principles, proteids, carbohydrates, and mineral constituents, but rather to retain them as far as possible in a digestible condition The preparation has recently been further improved By careful cooking and treatment with active malt the carbohydrates, and doubtless the proteids also have been reduced to an increased digestible state The preparation affords a very palatable and nourishing food

VIBRONA MALT

(FLETCHER FLETCHER AND CO, 469 HOLLOWAY ROAD N)

According to our experiments this is an active fluid preparation of malt containing in each fluid ounce 10 grains of cinchona in the form of neutral hydrobromate We found the preparation to be exceedingly active in digesting starch emulsion The taste of the malt which is pleasant, appears to mask the bitterness of the cinchona compounds According to its composition this preparation should possess distinct tonic as well as nutrient qualities It should be useful where the tonic properties of cinchona bark are indicated for children As is now well known cinchona in the form of hydrobromate avoids "cinchonism"

ELIXIR PHOSPHORI (HORN)

(O T HORN GLENDOWER, BOURNEMOUTH)

This is an aromatic syrupy liquid which is said to contain one fiftieth of a grain of pure free phosphorus per drachm It is miscible with water and compatible also with certain iron and quinine preparations From the results obtained on extraction with carbon disulphide we are able to confirm the statement that the phosphorus occurs in the pure elementary state of the yellow variety We note that it is stated on the label that the contents of the bottle must be used only for dispensing prescriptions of medical men Phosphorus is a well known nervine tonic and the solution under analysis is doubtless well suited for its administration. It is said also that phosphorus is useful in preventing the falling off of hair In any case it should not be administered indiscriminately but rather with caution

MOUILLA LIQUID SOAP (TEREBENATED)

(S MAW SON AND THOMPSON 7 TO 12, ALDERSGATE STREET E C)

Liquid soap is extremely convenient to use A few drops placed on the palm of the hand with a little water yield almost instantly on rubbing a pleasant and agreeable lather It is powerfully cleansing and without injurious effect upon the skin as long as there is no alkaline excess There is no alkaline excess in Mouilla liquid soap according to our experiments We should like to see the use of liquid soap more extended in the practice of medical men, since it should afford an excellent vehicle for antiseptics Thus it should be compatible with the solution of iodide of mercury in potassium iodide the compound forming a very powerful and convenient antiseptic Potash soap gives the impression of being a more powerful detergent than soda soap It cleanses the hands more rapidly and leaves a pleasant, cleanly feeling

DIABETIC CAKE

(J GABOR AND CO, 93, WALWORTH ROAD S.E., AND 2, TIDY-STREET BRIGHTON)

The composition of this cake is based on well known lines in accordance with the requirements of diabetic patients It contains a minimum of starch or other carbohydrates It is prepared from almond flour, the flavour being "nutty The cake is somewhat heavy and greasy, the smell of the oil present suggesting cocoanut While it is true that this cake is practically free from starch and on that account is adapted for the diabetic patient we doubt whether it is easily digestible

THE LANCET.

LONDON: SATURDAY, MARCH 4, 1899.

WE publish this week the result of an exhaustive inquiry which we have made into plumbers' work in its relation to water-supply and sewage disposal in rural districts. This report is supplementary to the Report on the Relative Efficiency and Cost of Plumbers' Work which we published on July 4th, 1896, and no one can read it without feeling how absolutely necessary it is for the safety of the community that the plumber should belong to a body known to possess a certain standard of knowledge.

The memorial recently presented to the Government praying them to deal with the registration of plumbers in the present session points out that while the proper qualification of medical officers of health and of sanitary inspectors has been provided for under the Public Health (London) Act, 1891, the qualification of the men whose intricate work they have to control, and upon the due execution of which so much depends, is left to chance. The memorial is signed by over 60 Members of Parliament, including many names of high repute. Another memorial has been sent to the Local Government Board signed on behalf of the Parliamentary Bills Committee of the British Medical Association, the Manchester and Salford Sanitary Association, the Royal Institute of British Architects, the National Health Society, the Royal Institute of Public Health, and the National Association of Master Plumbers of Great Britain and Ireland. Yet another memorial has been presented to Mr. Chaplin on the same subject signed by the mayor, the sheriffs, and the Bishop of Lincoln and by all the public, medical, and sanitary officials of that city with others interested in the question. This list of memorialists surely shows that many of those best able to judge of the matter are convinced of the necessity for additional legislation.

The evil that has to be combated is hydra-headed; deaths from diseases directly or indirectly attributable to defective sanitary surroundings and polluted water-supplies are numbered by thousands annually, and yet represent but a small proportion of the suffering arising from such causes. The plumber, the man who dominates that unseen world in which for our good or evil his works lie concealed in many a tortuous fold, is the man who must be educated and controlled. While we should welcome with satisfaction any measure to ensure a higher standard of technical and practical ability in the operative plumber, registration touches but the fringe of the question and this alone will not suppress the evils arising from defective work. We are apt to forget that while great advances in intelligence and education have been made by all classes during the past generation (the plumber not excepted) human nature is, and some think always will be, much where it was. Regrettable as it may be, an improvement in conscientiousness has not synchronised with the advance of education. Something more than a knowledge of right is required, and the wrong-doer must be coerced. The spirit of the times, the rage for cheapness (call it necessity or avarice, the result is the same); this it is that rules the market. Though it is satisfactory to know that men exist in plenty who would scorn to execute work at the behest of an employer knowing it to be faulty in conception or base in practice, yet there are many who would entertain no such scruple. It is not so much in the houses of the opulent and of the middle-class that defective work is flagrant (though many of these are in evil plight), as it is in the crowded town and suburban dwellings of the labouring classes and of the poor. Into these tenements, which spring up in a night like mushrooms the country through, swarm a half-cared-for population before the water used in the construction of their homes has evaporated from the plaster and bricks. It is here, where the plumber's work is sublet at from £5 to £10 per house, that every evil is rampant. How will registration alone touch the callous men who prostitute their abilities to do such work as this? The question is not one of the better class of plumbers and of those interested in their work desiring registration. Of course they desire registration, but the new legislation is not needed in their behalf. It is the public who require protection, not only from ignorance but from fraud.

To accomplish this should be the object of a short Act the broad provisions of which we may indicate without having the appearance of meddling with matters without our scope:—

(1) The men must be examined and registered by a competent board of examiners and afterwards granted an annual license.

(2) The holder of the license must be made directly responsible for his acts to the local sanitary authorities in whose district he is at the time working and his number must be registered in connexion with each individual house. It would be the business of the local authorities to report any dereliction of duty to the governing board. The board would, as they might see fit, mark or suspend the license.

(3) The vested interests of all existing plumbers would, of course, be respected, but all should be licensed, though in their case registration need not be compulsory. They must also be made responsible to the local sanitary authorities.

Some such measure would, we venture to think, in a comparatively short time greatly improve the standard of the work executed. It would not only insure the householder against the results of ignorance and incompetency, but it would to some extent eliminate fraud, under which inferior material or defective construction is substituted for sound work by the unscrupulous employer in order to enable him to undersell his more conscientious competitor. Its chances of becoming law, provided the Bill were promoted by the Government, are excellent. Each of the private Bills promoted by the Company of Plumbers was read a second time and each received the support of members of all shades of opinion in the House, so that the movement is neither a controversial one nor one that need be made from a party standpoint. It was rather apathy than opposition that blighted the early promise of a useful future presented by these private Bills and the apathy is at the first glance difficult to understand. It might be thought that the increased security which the Bills offered, or sought *to offer*, to the public would have been acceptable, at any rate in principle, to all Members of Parliament. Yet no one seemed to care about the registration of plumbers or to think it necessary to urge the measures upon the attention of the House. Why? Curious as the reason may sound, we believe fear of ridicule to have played its part in this neglect of an important matter. There is a certain atmosphere surrounding the plumber which prevents him from being taken seriously, unless indeed calamity ensues from his operations—the "something immejit" of Mr. ANSTEY's excellent story. To be very earnest about a subject which others find comic requires considerable courage. But such courage should not be wanting. The subject is not comic. It is serious, deadly serious in its public health aspects, and we hope that the current session will see it treated with the gravity and earnestness which it merits.

◆

THE recently issued report of the Departmental Committee appointed to inquire into the manufacture and use of water gas and other gases containing a large proportion of carbonic oxide is of considerable medical interest. Water gas, a mixture of hydrogen and carbonic oxide produced by passing steam through heated coke or anthracite, is an odourless and non-illuminant gas. For public lighting purposes it is "carburetted"—that is, enriched by hydrocarbons derived from oil. The resulting carburetted water gas smells much like coal gas; its candle power is greater; owing mainly to the small amount of labour required in its preparation it is on the whole cheaper to make than coal gas; and it has the additional advantage of possessing what the Committee call an 'emergency' value. Unexpected increase in the demand for gas, as by continued fogs, can at once be met by rapid gas manufacture, whereas with coal gas it is necessary to draw upon storage.

In many large towns of America carburetted water gas now forms the whole, or nearly the whole, of the municipal gas supply. In Great Britain a gas-supply consisting solely of carburetted water gas so far has been provided only in a few localities and for limited periods. But carburetted water gas is often employed for mixing with coal gas. A half and half mixture, for instance, is ordinarily used at Tottenham and Edmonton; gas at Birkenhead has occasionally contained as much as 64 per cent.; and gas in the northern part of London usually contains some 33 per cent. of carburetted water gas.

The danger of carburetted water gas lies in its containing about 30 per cent. of carbonic oxide, which in coal gas is present to between 4 and 12 per cent. only. In considering this danger the Departmental Committee put on one side all questions of injury to health from constant exposure to small leakages of gas of either sort. For illness thus produced apparently, in their opinion, carbonic oxide is not responsible. They "do not think that the existence of anything like chronic poisoning by carbonic oxide has been established." Hence their inquiry has virtually been limited to considering what is the proportion of carbonic oxide which may be allowed in an illuminating gas consistently with reasonable security against fatal result when the gas has been inhaled in relatively large quantities as, for instance, when a gas burner has been accidentally turned "full on" in a sleeping room. The danger from this sort of accident when all the gas is carburetted water gas cannot be regarded lightly in view of the evidence accumulated in this report. Dr. HALDANE, one of the Committee, points out that in the case of Boston, where 90 per cent. of the gas is water gas, about one in every 300 deaths is due to accidental poisoning by water gas. And in this country during the short time that carburetted water gas was supplied pure in a certain district two persons were killed and five were made seriously ill. Moreover, the Committee insist, very rightly, upon the risk that this gas might become a ready instrument of suicide and homicide. "The facility with which murder (particularly child murder) bearing all the appearance of accident, could be committed by simply turning on in a small room a jet of gas containing a large proportion of carbonic oxide, seems to us to afford an additional reason for restricting the use of carburetted water gas."

The most important of the recommendations of the Committee, to which they urge that effect should be given by Act of Parliament, consists in their advocacy of a statutory limit of 12 per cent. of carbonic oxide in any illuminating gas. In special local circumstances of pressure and the like, however, they consider that a maximum limit of 20 per cent., which would permit a mixture of equal volumes of coal gas and water gas, might be allowed. As the danger is principally to persons when asleep they point out that these statutory limits need only be imposed in the case of gas supplied at night.

The limits suggested have been arrived at in consideration of a valuable series of experiments by Dr. HALDANE upon the proportions of carbonic oxide in the air of rooms into which coal gas escapes. The basis of his experiments is the assumption that no serious danger to man arises from several hours inhalation of air containing carbonic oxide in less proportion than 0·2 per cent., and, which by the way is much more certain, that a proportion between 0·2 and 0·4 per cent. is dangerous to life, while over 0·4 per cent. may cause death rapidly. The amount of escaping gas being constant and the cubic capacity of the room experimented upon being known, the question whether or not with a gas containing a known proportion of carbonic oxide the dangerous percentages will be reached becomes one of the ventilation provided. There are, however, few reliable data as to the frequency with which the air of an ordinary "stuffy" bedroom is changed. Dr. HALDANE's experiments add materially to our knowledge on the point. It is interesting to find that his results are in accord with those of PETTENKOFER in the worst case which has to be considered in this connexion—that of a small room with door, windows, and all other openings closed. A much larger amount of air often passes through such a room than at first would seem possible. In a completely closed room of 1000 cubic feet, for example, Dr. HALDANE estimates that the maximum time needed for the entry of a volume of air equal to that of the room is less than two and a half hours. It must, however, be remembered that diffusion of air in this way through walls, floors and ceiling is directly dependent upon the difference of temperature between the air of the room and the air outside. As providential diffusion of this sort cannot always be reckoned on to come to the aid of persons exposed to poisoning by gas the Committee have, we think, done well to advise the restriction of carbonic oxide in ordinary gas-supplies to proportions which are not likely often to do serious harm even when escape takes place into a room which is practically unventilated.

◆

THE effect of MR. BALFOUR'S London Government Bill on medical officers of health in London will be to add to their labours and responsibilities. They will be directly concerned in the administration of the law relating to dairies, cowsheds, milkshops, slaughter-houses, and knackers' yards, to say nothing of the law relating to noxious trades and common lodging-houses. Thus they will be placed in a position similar to that of the medical officers of health of other urban authorities, except that cowsheds, slaughter-houses, and knackers' yards will not be licensed by the suggested municipalities but by the London County Council. The business of a slaughterer of cattle and all noxious trades when established anew will require the sanction of the County Council as heretofore and not that of the new authorities, and all regulations and by-laws will still be made by the County Council. This is, we think, a wise division of duty and one which should work for uniformity of procedure. Perhaps a more irksome duty will devolve on the County Council than before, for they are to be held responsible for the sufficiency of action of the several authorities in respect of their new duties by being given power of supervision over a defaulting authority. It is obviously much easier to institute the necessary proceedings against a careless cowkeeper or butcher than to persuade or coerce an authority which has its own views to take the necessary proceedings. In short the work of the medical officers of health of the district authorities will be added to, and the anxieties of the medical officer of health of the county of London are increased under the Bill.

The proposed changes, however, are obviously in the right direction, although a strong case can be made out for the desire of the County Council to retain the administration of the common lodging-houses until provision has been made for the annual licence of such premises by the Council. This power has already been given to local authorities in Scotland under the recent Public Health (Scotland) Act and is certainly more necessary in London than in Scotch towns. While the duties of medical officers of health in London districts will be thus increased in many districts the area for which they are appointed will be added to. The 45 districts in London will probably be thus reduced to some 30, and this increase in responsibility and work should not be lost sight of. London especially needs capable and zealous medical officers. If there is failure on the part of the officer of a district authority in the provinces that district is probably the only sufferer, but if there is such failure on the part of the officer of a London district neighbouring districts may also suffer, whatever may be the vigilance of the officers of the County Council. There is urgent need that London should have good medical officers, and the only way in which this can be assured is by the payment of salaries adequate to secure men of sufficient ability and influence. We earnestly hope that this point will be considered in any appointments which are made as the result of the passin of the London Government Bill.

We are not now concerned in considering whether the districts to be constituted under the Bill will be of convenient size for the purposes of sanitary administration, although we note with some surprise that the Bill suggests that they may have populations as large as 400,000 inhabitants. There are other points in the Bill to which we may have to refer later, but on the whole we consider that it is a measure in the right direction, although it obviously provides only partially for the changes which must inevitably be effected in the future.

Annotations.

"Ne quid nimis."

INCIPIENT INSANITY.

THE satisfactory treatment of patients suffering from incipient insanity or of those in whom the diagnosis is doubtful is rendered difficult owing to the Lunacy Laws as now framed. In the first place, the medical man hesitates to sign the certificate if there is the least doubt about the patient's condition and, secondly, the friends of the patient object to removal to a recognised asylum unless there is some very obvious reason why home treatment is undesirable. There unfortunately exists an idea that some stigma attaches to the certification of a patient as insane and the general public cannot be brought to understand that insanity is the misfortune and not the fault of the affected person, and that the conditon if suitably treated may end in recovery. Like any other disease the prognosis is more favourable if special medical advice be sought when the malady is at an early stage, but too frequently this course is postponed owing to the reasons stated above until the patient has fallen into confirmed insanity. A joint committee of the British Medical Association and the Medico-Psychological Association has drawn up a draft clause for providing temporary care of persons suffering from incipient or unconfirmed mental disease, and the following is the text of that clause:—

DRAFT CLAUSE.

1. Where a medical practitioner certifies that a person is suffering from mental disease but that the disease is not confirmed, and that it is expedient with a view to his recovery, that the patient should be placed under the care of the person whose name and address are stated in the certificate for the period also therein stated not exceeding six months, then during that period the provisions of Section cccxv. of the Lunacy Act, 1890, shall not apply.

2. A medical practitioner who signs such certificate shall within three days after signing the same send a copy thereof to the Commissioners and it shall be lawful for any Commissioner to visit the patient. The person under whose care the patient is placed shall not be the person who signs the certificate.

3. The person who receives a patient under such certificate shall within 10 days after the expiration of the period mentioned in the certificate, or if he ceases to have the care of the patient under the certificate at an earlier date then within 10 days after such earlier date, send a report to the Commissioners stating whether the patient recovered, and if not, in what manner he was dealt with when the person making the report ceased to have the care of him under the certificate.

The committee also drew up a form of certificate as follows:—

CERTIFICATE.

I [*insert full name and address*] a duly registered medical practitioner certify that [*insert name, address and description of patient*] is afflicted [*state the nature of the disease*], but that the disease is not confirmed, and that I consider that it is expedient with a view to his [*or her*] recovery that he [*or she*] should be placed under the care of [*insert full name and description*] at [*insert full address of the place where the patient is to be received*] for a temporary residence for a period of [*specify a period not exceeding six months*] from the

Dated day of , 18 Signed

A deputation representing the joint committee were received by the Lord Chancellor on Feb 22nd. The views of the committee were expressed by the chairman (Dr. Rayner), by Dr. Blandford, and by Dr Savage The Lord Chancellor evidently attached much importance to the representations made to him and left the impression by his reply that he was not indisposed to initiate legislation in the direction desired though he took exception to the period of probation, six months, as being too long. The committee will have the thanks of the whole profession if as the result of their labours the much needed reform is effected Similar provisions have been in force in Scotland for 30 years and experience has proved them to work advantageously

SANITARY AUTHORITIES AND THE INSPECTION OF PREMISES

AN important decision was recently given in the Queen's Bench Division of the High Court having reference to the powers of sanitary authorities to enter upon premises within their district to ascertain whether they are in a sanitary condition. A duly authorised inspector of the St Pancras Vestry attended at the North London Collegiate School for the purpose of entering and examining as to the existence therein of any nuisance and admission was refused An application was then made to Mr Plowden, stipendiary magistrate, for an order This was refused on the ground that in point of law there was no evidence of reasonable ground for such entry The St Pancras Vestry appealed against the decision. Mr Justice Lawrance with whom Mr Justice Channell concurred in delivering judgment, said that the magistrate had a right to ask, "Why do you want to go in?" and the mere reply that "I wish to go in because the statute gives me power to go in" is not a reasonable ground Under the circumstances the magistrate was perfectly justified in refusing the right to enter According to this ruling it is obvious that medical officers of health and sanitary inspectors have no right to enter any premises save with the consent of the occupier, to examine as to the existence of any nuisance unless they have reasonable grounds for suspecting the existence of a nuisance and that the magistrate is the sole judge of what constitutes a "reasonable ground" It is probable also that any officer entering premises for the purpose of inspection without first obtaining the permission of the occupier is liable to an action for trespass This decision will be far reaching in its effects as it has hitherto been assumed that sanitary officials had the necessary power of entry for inspection purposes The present condition is most anomalous. Medical officers of health and inspectors of nuisances are in duty bound to make periodical systematic inspections of their districts and yet they have no legal right enabling them to do this. The practical effects of the decision remain to be seen but may not be so serious as at first sight they appear Entry, when requested in a respectful manner, is very rarely refused and many officials have never yet been refused It will however, no longer be safe to assume that the power of entry exists and permission should be asked and obtained in all cases, whether it is desired to enter a mansion or the humblest dwelling. As a medical officer has no right to enter a school to examine for a nuisance it is very probable that he has still less right to enter a school to examine the scholars In certain cases such "rights" are desirable and in any amendment of the Public Health Acts an attempt should be made to secure the requisite powers for making these inspections

"EMBALMED" MEAT IN THE AMERICAN ARMY.

THE "embalmed" beef question has of late been a disturbing factor in political, army, and medical circles in the United States. For some considerable time murmurs of discontent have been heard regarding the state of some of the canned meat sent out to Cuba, Porto Rico and Manila as food for the American soldiers in those places Matters, however, might not perhaps have come to a head had it not been that General Miles who is under the President at the head of the army and who commanded the United States expedition against Porto Rico, gave to the lay journals his opinions on the subject in the following strong terms "In addition to the reports of the regimental commanders I have a great mass of evidence consisting of communications affidavits &c., from officers soldiers, and civilians Every part of the country has contributed to the mass of correspondence which I have received in reference to the beef served to our soldiers and the evidence is all corroborative of what I have said The great publicity which the press has given to the matter has brought all the correspondence of which I speak unto me I have overwhelming evidence that the embalmed beef was treated with chemicals in order to preserve it. I have affidavits from men who saw the beef undergoing the treatment or embalming process. Now as to the canned roast beef, that was different from the embalmed beef The canned roast beef was the beef after the extract had been boiled out of it You have seen the advertisements, 'Beef extract—one pound contains the substance of from four to five pounds of prime beef.' Well, this is the beef after the extract has been taken from it They put this beef pulp up in cans and label it 'canned roast beef.' The soldiers report that the canned beef was nauseating If swallowed it could not be kept on the stomach I have no interest to serve but the army and the country When I found that it was the chemicals in the beef that had made the soldiers sick then I ordered an investigation and reports to be sent in So widespread is the evil that all the reports are not in yet They are overwhelmingly of the same character—all showing that the beef had been embalmed or was otherwise unfit for men or dogs Half a million pounds of this beef came in one ship to Porto Rico The soldiers were 60 miles away in the mountains The beef was so bad that it would have caused a pestilence had it been taken ashore from the ship So it had to be thrown overboard What else could be done with it? Nothing alive could eat it" Owing to General Miles's plain speaking the Government ordered an investigation of the matter to be made but the testimony offered has been of so conflicting a nature that no very definite result has been arrived at It should be said that it is claimed that boric and salicylic acids were the chemicals used to preserve the meat Naturally, the medical journals of America have been devoting a good deal of their space to a consideration of the subject and the *New York Medical Record* in its issue of Feb 4th has this to say with regard to the use of chemicals as preservatives of meat: "Worse than all, however was the unwarrantable experiment of adding chemicals in the shape of boracic and salicylic acids to prevent decomposition The overwhelming testimony of such as used the 'embalmed' beef is to the effect that it was offensive to the sight smell and taste was to the last degree unappetising and unwholesome, and that in very many instances it produced much of the digestive troubles which so largely prevailed among the soldiers.

This latter state of affairs can be easily explained by the ingestion of the toxins of decomposing animal food on the one hand and the constant admixture of chemical products with the food in question on the other. As there is no proof to show that boracic and salicylic acids are absolute preservatives it is fair to presume that the 'embalmed' beef was not only more or less decomposed but was artificially 'doctored' besides. Thus the two conditions were combined to make the men sick." From the very commencement of camp life much dissatisfaction has been expressed by the United States volunteer with the quality of the food supplied to him. No doubt this prejudice was largely due to the fact that he was in most instances "a green hand" and not inured to campaigning hardships, but with regard to the canned beef proof has clearly been afforded that a large proportion of it was unfit for human food—whether owing to defective packing or to the use of chemicals will, it seems, never be demonstrated to the satisfaction of the general public. At least, however, the investigation will do good to the extent of opening the eyes of the American people to the fact that adulteration of some kind is practised by the big preserved meat packers and such a sentiment will be aroused against the principle that these men will be compelled in their own interest to amend their ways and to supply wholesome canned meat.

DEATHS UNDER ANÆSTHETICS.

A death under ether occurred at the Paddington Infirmary on Jan. 30th. The patient was a well-developed and well-nourished man, aged 51 years. For the last three years he appears to have had attacks of *petit mal;* his lungs were emphysematous, but otherwise he was healthy. Ether was given from a Clover's inhaler with a view to the performance of an operation for the relief of urethral stricture. Methylated ether of the specific gravity of 0·720 was used. No struggling or unusual symptoms occurred—we are told by Mr. Sidney Vines, to whose courtesy we are indebted for careful notes of the case—during the period of administration. The breathing was somewhat shallow but never laboured and in four minutes when complete anæsthesia was present the respiratory rhythm was normal. At this time the colour was good, the pulse was regular, the pupils were moderately dilated and reacting to light, but the conjunctival reflex was abolished. The indicator of the inhaler was then standing at "3," and was turned to midway between "3" and "2," and the patient was pronounced ready for operation. Suddenly, and before the surgeon had commenced, the pulse intermitted; a few irregular, feeble beats occurred, and it then ceased, respiration grew shallow, and the patient's face became cyanosed. The pupils remained of medium size and the ocular globes were fixed. A distinct inspiratory effort was made after cessation of the pulse. Restorative measures, although promptly adopted, failed to effect resuscitation. This is a case of peculiar interest, as the phenomena described are most unusual under ether, as indeed is the termination. The administration seems to have been conducted in the most careful and accurate manner, so that the death was certainly not the result of overdose, insufficient aeration of the lungs, or failure of circulation from strain imposed upon the heart by muscular spasm. It is possible that the syncope was the result of a fit such as the patient was in the habit of having, possibly brought on by the excitement and trepidation incident to facing an operation under an anæsthetic—a first experience. Such seizures occur even under profound narcosis but do not necessarily result in fatal syncope in all cases. It is unfortunate that no post-mortem examination was made, as the condition of the viscera and especially of the brain and kidneys would have somewhat guided the clinician in his classification of so unusual a case of death under ether. A death under chloroform occurred recently at the Metropolitan Hospital. The patient was a man, aged 37 years, suffering from strangulation and gangrene of the intestine due to a volvulus. He was given chloroform by a house physician with a view to operation but he died under the anæsthetic. We have not been favoured with any particulars as to the method employed or as to the phenomena of the induction, but we gather that the man was probably *in extremis* at the time the chloroform was employed. In conditions of such grave collapse it is usual to employ ether or the A.C.E. mixture but why the choice fell upon chloroform we have no means of judging. A death, also under chloroform, is stated to have occurred at the Royal South Hants Infirmary on Feb. 2nd. The patient, a man, aged 33 years, suffered from an abscess affecting the chest wall and sub-sternal tissues. This was opened under chloroform, but as recovery was not satisfactory a further operation was judged to be necessary. When chloroform was given (? method) the man struggled, became rigid, and ceased to breathe. At the inquest it was stated that death probably resulted from pressure of the matted tissues upon the vagus. Unless the facts are very much distorted—which can hardly be the case, as we understand that the report is fairly accurate—the cause of death was the usual one in such cases—an overdose of chloroform taken during the period of struggling. The vagus nerve has so many functions that it must be always a factor in death, but it is very seldom that mechanical and slowly exerted pressure leads to more than alteration of the cardiac rhythm. No doubt dragging upon the vagus during dissecting operations about the sterno-mastoid region does produce a marked degree of inhibition, but not, we believe, rigidity with respiratory paralysis. These are practically always the result of poisoning of the medullary centres by a *too* concentrated vapour of chloroform inhaled sometimes in a single deep inspiration such as commonly occurs after a prolonged period of holding the breath while struggling. All methods such as pouring unmeasured quantities of chloroform upon any surface from which it is inhaled lead to such overdosage as the administrator has no power to limit or to prevent at the critical moment, save that of removing the cloth or other "apparatus" from the patient's face, and this is unhappily seldom done until the fatal overdose has been inhaled.

THE SAFEGUARDING OF THE NILE.

Objection of a more or less sentimental character was taken to the statement by Mr. Brodrick in the House of Commons that the body of the Mahdi had been thrown into the Nile but none of the honourable Members present seem to have noticed the highly important signification of the act when regarded from a sanitary point of view. With the alleged desecration we are not specially concerned but the preservation of the waters of the historical river from organic pollution is a matter which cannot but prove of interest to all hygienists. Unlike other countries Egypt is entirely dependent on the Nile for its supply of drinking-water. There are no springs or wells properly so-called to be found from one end to the other of the immensely long groove which the great stream has worn for itself on its way through the Libyan desert to the Mediterranean. Wells or shafts for water certainly do exist, some of them of a considerable depth, but all without a single exception are fed by the Nile and would speedily run dry were the bed of the river to be diverted. It is therefore of the utmost importance that the wholesomeness of the Nile water should be religiously maintained. Of course the amount of contamination produced by one human body could only be insignificant, but it would be a truly serious calamity if the people of Egypt were to get hold of the idea that in the eyes of the executive the purity of the river was a matter of little or no consequence. Already the tendency to dispose of putrescible material by casting it into the stream is far too common. If the fellah were not afraid of contravening the sanitary notions of his exotic rulers the Nile would very soon be converted into a general sewer. That it partook of this character not so very long ago is, we believe, an undoubted fact, but of late years under British impulsion a good deal in the way of purification has been accomplished. The task no doubt is full of difficulty, involving as it does a radical change in the habits and customs of an entire nation, but if it is to be carried to a successful issue the hands of the sanitary officials should be strengthened and not weakened. Since the foregoing was written we have learned that, notwithstanding the statement in Parliament, there are still considerable doubts regarding the actual disposal of the false prophet's remains. According to a morning contemporary[1] Mr. Brodrick was not quite accurate in stating that the body of the Mahdi was thrown into the river. The tomb at Omdurman was no doubt opened, but the skull and some of the bones are at present in the possession of officers who took part in the campaign. A portion of the coffin, too, has been preserved as a memento of the overthrow of Mahdist tyranny in the Soudan. It is sincerely to be hoped that this is the true story. That Lord Kitchener with his training as a Royal Engineer could ever under any circumstances have given orders for a dead body to be thrown into the Nile was, on the face of it, well-nigh incredible from the first.

THE MORTALITY FROM DRINK.

DR. WILLIAM CARTER of Liverpool has been delivering a public lecture on drink in which he draws attention to several points. Amongst others, arguing from the returns of the Registrar-General, he shows that the deaths directly attributed to intemperance in 1896 were 91 per 1,000,000 among males and 52 per 1,000,000 among females, these rates being considerably in excess of the mean rates in the 10 years immediately preceding. We are constantly assured by politicians that drunkenness is diminishing. Dr. Carter says: "Year by year almost without a single break in its cruel and pitiless progression the mortality from drunkenness has been, and is, increasing, and it shows what is worse than all and what should arouse the national conscience, or if the conscience is dead or asleep should rouse the nation to a sense of its imminent danger—viz., that the deaths are increasing among women far more rapidly and in a far greater ratio than among men." He gives particulars to show that whereas in the years 1876–80 38·4 deaths from the direct effects of alcohol occurred in every 1,000,000 people living, in the years 1891–95 68 such deaths occurred, an increase of 80 per cent. In the last period over the first, reached steadily and progressively through the years of the intervening period. Perhaps the most important part of Dr. Carter's address is that in which he shows the much greater rate of increase of mortality from drink among women than among men, so that whereas the proportionate increase of deaths from this cause among men has been 42 per cent. up to 1895, that among women has been more than 100 per cent. This is brought out very strikingly in the case of the deaths not returned as alcoholic, but which medical men know to be mainly such in their causation—in particular, cirrhosis. The increase of deaths from this cause is in the case of males in the last 30 years at the rate of 300 per cent. and in the case of females at practically 400 per cent. Dr. Carter refers very eloquently to his investigations with Sir Henry Littlejohn and to the classical investigations of Dr. Parkes and Dr. Sanderson into the sanitary condition of Liverpool. Dr. Carter is puzzled, as all medical men must be, with the comparative indifference with which mortality of this sort is regarded by the public and by sanitary authorities as compared with mortality from infectious and notifiable disease. The deaths of 22·4 persons per 1,000,000 from typhus fever from 1877 to 1881 inclusive stirred the sanitarians and the public and more stringent sanitary legislation was procured with the result that the mortality from typhus fever has fallen in 1896 to two per 1,000,000. In the same period 43·3 per 1,000,000 died directly from alcohol, to say nothing of indirect mortality. We hear no such protest from sanitarians and the mortality goes up to 91. It is a hopeful sign when physicians of Dr. Carter's standing, with a great medical experience of life in such a city as Liverpool, give prominence to such grave facts Whether such drunkenness is cause or effect may be matter for argument. It coincides with an enormous expenditure on sanitary improvements and an equal improvement in the social and economic conditions of the people and ought to receive the immediate attention of the nation.

"THE TUBERCULOSIS PROBLEM IN THE UNITED STATES."

THERE is much that is interesting in a paper with the above title in the *North American Review* for February by Dr. J. A. Knoff. With the greater part of his remarks we agree, but with others we cannot concur. For instance, he states that consumption "is the disease which the power of man could cause to disappear from the world with more certainty than any other." We believe that most medical authorities would consider small pox, typhus fever, and rabies far more preventable than tuberculosis, although by suitable precautions the death-rate from tuberculosis could be lowered even more than at present is the case. Dr. Knoff not only expresses the opinion as to the possibilities of diminishing tuberculosis, but also proposes a scheme by which he thinks a great deal could be done towards that very desirable end. He says: "Just as there exists in nearly all States or municipalities a commission or a number of special examiners for the purpose of determining who is a proper subject for State care in an asylum for the insane, so should there exist a commission for the determination of admission to a municipal or State institution for consumptives." Dr. Knoff enters into considerable detail as to the carrying out of such a scheme. He suggests that a committee should be formed consisting of physicians and laymen for the following purposes: to determine the applicant's condition by a medical examination; to visit his home if he has been found tuberculous and to institute such hygienic measures as seem necessary; and to examine the other members of the family in order to find out if any of them have also contracted the disease and, if so, to counsel proper treatment. Then follows a very drastic proposal—to report in full to the sanitary authorities concerning the condition of the patient's dwelling and suggesting its renovation or even destruction when it is evident that tuberculosis has become "endemic" there owing to the condition of the soil or to other sanitary defects. We doubt whether any sanitary authorities would ever consent to such extreme measures even if they could be proved necessary. A house might be deemed insanitary owing to the condition of the drainage, but to insist on its demolition would require a stronger authority than a committee formed on the lines which Dr. Knoff proposes. Finally, a suggestion is made which would be sure to meet with such strong opposition that its adoption would be almost hopeless—the committee is to determine the financial condition, whether the patient is or is not able to pay and whether or not by his being taken to an institution the family will become destitute. "If the latter should be the case it would become an imperative duty for the municipality to provide for the family." Considering the enormous prevalence of tuberculosis among those entirely unable to pay for the prolonged treatment necessary, such a scheme can only be considered to be utopian. With another part of Dr. Knoff's paper we most strongly agree. He says: "In reality, pulmonary tuberculosis is not a contagious disease, the contact *per se*, the touch of the invalid, is not capable of transmitting the disease; it is the ignorant, unclean, or helpless patient who by his mode of disposing of his expectorations endangers the life of others. ...... Thus it is more correct to call pulmonary tuberculosis only a highly communicable disease and we repeat, from living or coming in contact with a clean, conscientious, tuberculous invalid, nothing whatever is to be feared." Such words are likely to have a considerable influence in calming the unnecessary alarm which has arisen in lay minds as a consequence of classing "consumption" amongst "infectious diseases."

[1] The Morning Post, Feb. 21st, 1899

PARALYSIS OF THE SOFT PALATE FOLLOWING NON-DIPHTHERITIC SORE-THROAT.

IS paralysis of the soft palate following sore-throat a proof that the disease was diphtheria? Most clinicians would probably say yes. But analogies which prevail among the infectious diseases, and the occasional occurrence of what is a common complication of one as a very rare one of another, ought to raise some doubt. Multiple neuritis may occur in many diseases and may not the palatal paralysis of diphtheria, which is probably a local effect of the diphtheritic toxin, be produced by other toxins? The following case, brought before the Société Médicale des Hôpitaux by Professor Carrière, is of great importance and appears to be quite conclusive. A woman, aged 20 years, was seen on the third day of an illness which was attended with rigors and pain in the back. The temperature was 100·2°F., the face was pale, and the cervical glands were enlarged. The uvula, the soft palate, the fauces, and the tonsils were covered with greyish-white, adherent false membrane which penetrated into the tonsillar crypt. The mucous membrane beneath was bright red and hæmorrhagic in places. Cultures were made repeatedly and they showed only streptococci and staphylococci. In spite of energetic local treatment the membranes were rapidly reproduced. Improvement began on the sixth day; the throat was red and free from membranes on the seventh. The glandular enlargement lasted for about 15 days. On the twenty-seventh day the patient noticed that her voice was nasal. There was total paralysis of the soft palate. Under faradaisation recovery took place in about three weeks.

THE CORPORATION OF HASTINGS AND THE HASTINGS DRINKING-WATER.

THREE or four weeks ago the town clerk of Hastings, instructed by the Water Committee, wrote to the local paper to say that all the water supplied to the borough had been analysed and was "chemically of high quality." The analysis was not given and one of the ratepayers asked to see it, promising not to publish it without permission. He was informed, no other reasons being given, that "it has not been the practice to furnish individual ratepayers with details of the analyses from time to time made of the water supplied to the borough and that the committee cannot see their way to make an exception in your favour." The ratepayer replied that if desired he would pay for the information, for it was but natural that he should wish to know what he was drinking and that the mere assurance of the corporation that the water was good for him personally was not quite sufficient. He also pointed out that he had not promised to refrain from publishing any analysis which he himself might make and that if the corporation persisted in secrecy he was afraid people would draw their own inferences. Two men then called at his house and took away a sample of the water and a few days afterwards he received a letter from the town clerk telling him that the Water Committee "had nothing to add to previous communications." The Hastings Corporation can hardly expect that all its constituents will consent to be treated like children and will swallow in perfect confidence what it pours down their throats. Of course, as the ratepayer said, conclusions will be drawn and if they are unjustly unfavourable the corporation alone is to blame. The phrases "not been the practice" and "nothing to add" show, as has often been observed before, that the provincial Tite Barnacle is much more official than his brother at Whitehall.

THE LEAGUE OF MERCY.

WITH the Prince of Wales as President and the Princess of Wales as Lady President a League of Mercy has been formed for the purpose of promoting the welfare and furthering the objects of the Prince of Wales's Hospital Fund for London. A special object of the league is to encourage personal service in promoting the adequate maintenance of hospitals and an "Order of Mercy" has been established which will be conferred as a reward for gratuitous personal services in this direction. We hail the foundation of the league as yet another proof of the Prince of Wales's broad sympathy and no less of his sagacity, while we note with particular pleasure that the services to be rewarded must be personal.

THE SMOKE NUISANCE.

WE have received an advance copy of the prospectus of the Coal Smoke Abatement Society. Its President is Sir William Richmond, its secretary Mr. Owen B. Thomas, and its treasurer Dr. Des Vœux; while the offices are for the present at 59, Chancery-lane. We are glad to see that such a society has been formed, for we have done our best for some time past to rouse the sanitary authorities to take action and to incite magistrates to convict in cases where the feeble defence of "No Welsh coal" was put forward. Besides the strict enforcement of the existing laws against black smoke there should be another passed making it illegal for any house to be built in future without being fitted with proper smoke-consuming appliances. We may mention that the annual subscription to the society is 5s., but subscribers may give more if they like.

THE PRESENTATION OF THE FREEDOM OF THE CITY OF LONDON TO SIR HUGH OWEN, G.C.B.

THE ceremony of admitting Sir Hugh Owen to the Freedom of the City of London upon his retirement from the position of Permanent Secretary to the Local Government Board, the duties of which he has so long and so ably fulfilled, took place in the Guildhall Council Chamber on Feb. 24th. The Master of the Worshipful Company of Plumbers (Mr. Alderman Hind) occupied the chair, for with obvious fitness it was as a liveryman of the Plumbers' Company that Sir Hugh Owen was admitted to the Freedom of the City. In addition to the wardens, and a special court of the company the Master was supported by the Lord Mayor and Sheriffs, Mr. Chaplin (President of the Local Government Board), the Earl of Onslow, Earl Fortescue, Lord Welby, Sir Richard Webster, G.C.M.G. (the Attorney-General), Mr. McKinnon Wood (Chairman of the London County Council), and a large and influential gathering of Members of Paliament and representatives of Government municipal departments more or less intimately associated with Sir Hugh Owen in his work. The Lord Mayor on behalf of the citizens welcomed the new Freeman while Mr. Chaplin on behalf of his department bore personal testimony to the excellent work done by Sir Hugh Owen and to his many sterling qualities Mr McKinnon Wood, as representing "Greater London," referred to the enormous and ever-increasing amount of work carried out by the department over which Sir Hugh Owen was the acting chief, the amount of which work the public generally had no means of appreciating. The simple ceremony of taking the oath and signing the roll having been gone through, Sir Hugh Owen in returning thanks spoke of the interest taken by the Plumbers' Company not only in the craft which they represented but in questions of public health

MUNICIPAL BACTERIOLOGY.

FOLLOWING the announcement in our issue of Feb 18th that the vestry of St Giles had made arrangements for the bacteriological examination of suspected cases of typhoid fever and diphtheria we now have pleasure in noting that the board of works for the district of Poplar and Bromley has decided as an experiment for two months to supply diagnosis boxes, sterilised, to medical practitioners for use in suspected cases and to submit the same when charged to bacteriological examination This excellent innovation is due to the energy of the medical officer of health, Mr F W, Alexander, and we sincerely hope that at the end of the two months the arrangement will be found to be worthy of being made permanent

THE GENERAL MEDICAL COUNCIL.

THERE has been considerable activity in the offices of the General Medical Council during the last week The committee appointed to watch legislation on the subject of midwives and its agreement with the views of the Council sat on Saturday last On Monday the usual meeting of the Executive Committee in the interval of the sessions of the Council was held, and on Tuesday the first meeting of the Penal Committee since the November meeting of the Council took place The premises of the Council are in the hands of builders who in accordance with the resolution of the Council in December are adding to the height of the building and providing additional rooms which are much needed

THE new laboratories in connexion with the Middlesex Hospital Medical School are now completed and are equipped with all the best modern appliances for the purpose of instruction and original research An inaugural conversazione will be held on the evening of March 15th in the new buildings when many objects of interest will be exhibited

THE council of the Medical Society of London, on the recommendation of a special committee, have awarded the Fothergillian gold medal for 1899 to Dr S Monckton Copeman "in recognition of his researches on the preservative effects of glycerine upon vaccine lymph and of the benefits in a practical sense that have arisen therefrom"

WE understand that Sir Samuel Wilks is not likely to offer himself for re election as President of the Royal College of Physicians of London at the meeting to be held on March 27th

THE St Patrick's Festival Dinner of the Irish Medical Schools' and Graduates' Association will this year be held on Saturday, March 18th, at 7 15 P M, at the Café Monico, Piccadilly circus, the President, Sir William Thomson of Dublin, in the chair. The association will have the honour of entertaining as the guest of the evening a distinguished Irishman—General Sir George White, V C, G C B, G C S I G.C I E, the Quartermaster-General and late Commander in Chief in India As a large attendance is anticipated members should make early application for dinner tickets to the honorary secretary, Mr P. J. Freyer, 46, Harley street, W.

MR WALTER FRANK RAPHAEL WELDON, M.A, F R S late Fellow of St John's College, Cambridge, and Professor of Zoology at University College, London, has been elected Linacre Professor of Comparative Anatomy at Oxford in place of Professor Ray Lankester, resigned.

AT the annual meeting of the Royal Medical and Chirurgical Society held at the rooms of the society on Wednesday last, March 1st, Mr Bryant was re elected President

PROFESSOR RAY LANKESTER, the Director of the Natural History Museum (British Museum), has been elected a Correspondent of the French Academy of Sciences

LORD LISTER has been made a Correspondent of the Paris Academy of Medicine

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE fifty fourth sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Feb 21st The Commissioners present were the Chairman (Lord Llandaff), the Right Hon John William Mellor, Sir John Dorington, Mr de Bock Porter, Mr. Robert Lewis, and Major General Scott

The examination of Mr. HARRY WILKINS, secretary to the Lambeth Waterworks Company, occupied the whole of the sitting The witness contradicted some statements with regard to financial matters which had been made by Mr. Gomme, a witness who had given evidence on behalf of the London County Council In the course of the evidence some information was given with regard to the water supply of Croydon It may be remembered that part of Croydon is supplied both by the municipal waterworks and by the Lambeth Company A case occurred in which the new owner of a house had preferred to have the water supplied by the corporation The charges made by the corporation of Croydon for their water supply were formerly less than those made by the Lambeth Company and complaints had at that time been made with regard to the quality of the water supplied by the Company. The witness ascribed these complaints to the fact that they charged more for water than was charged by the corporation; they therefore reduced their prices in the year 1894 and since that time they had not had a single complaint of the inferior quality of the water which they supplied At the present time, the witness stated, the people of Croydon were charged the same price by the Lambeth Company and by the Croydon Corporation

In answer to Mr DE BOCK PORTER the witness said that they had not lowered their charges in Croydon because of the competition but because of the allegations as to the quality of the water which they supplied. If it got abroad that the quality of their water was inferior they would suffer a very heavy loss and it answered their purpose to come down to the Croydon charges in order to disprove that allegation

The CHAIRMAN asked the witness whether the charges made at Croydon were sufficient to make a profit on the water which they supplied there. The witness replied that "whether they did or did not was immaterial"

In answer to Sir JOHN DORINGTON the witness said that last year one of their customers had withdrawn his custom from the company and taken the supply of the Croydon corporation He stated also that a medical man at Croydon had recommended one of his patients to take the Lambeth water in preference to that supplied from the chalk well of

Obituary.

SIR JOHN STRUTHERS, M.D., F.R.C.S. EDIN., LL.D. GLASG.,

EMERITUS PROFESSOR OF ANATOMY IN THE UNIVERSITY OF ABERDEEN.

SIR JOHN STRUTHERS died at his residence in Edinburgh on Friday, Feb. 24th. He was born in 1823, at Brucefield, near Dunfermline. He was one of three brothers who, like his own three sons, entered the profession of medicine. Edinburgh then, as now, was the leading medical school of Scotland, but, as Struthers was always fond of saying, the University benefited by the "Colleges," which he always advised young graduates to join. In 1845 he took his M.D. degree. In the same year he became F.R.C.S. Edin., and no doubt his devotion to the Royal College of Surgeons of Edinburgh may be explained by the fact that it was there, after his apprenticeship as demonstrator at the University, that he first felt his power as a teacher of anatomy. He was a keen and persistent dissector. To this as to every other of his pursuits, he gave himself without after-thought. *Quicquid agis, age pro viribus* was an axiom with him. He used to tell with regret how from his devotion to the scalpel he missed one afternoon a great scene in the history of Scotland—the solemn procession of the Disruption which was the beginning of the Free Church of Scotland. But the absorption was characteristic. Even at this early stage he was much more than a lecturer on anatomy. The extra-mural school did not then occupy the proud position of extra-University that it has since achieved; and Struthers was a leader in securing its recognition.

After some 16 years of vigorous teaching and reform in Edinburgh he was appointed in 1863 to the Anatomy chair in Aberdeen University. The University of Aberdeen, as we now know it, made by the fusion of two historic universities, was then only three years old. The medical faculty had its home in Marischal College where some of the class-rooms stood vacant because the "arts" had been transferred to King's College. But there was only one laboratory, which was reserved for chemistry. There was a dissecting-room, but in Struthers's opinion it was hopelessly inadequate. Forthwith he asserted, in Senate and in council, the claims of science. In those days the teaching of classics dominated everything. The two great liberalising forces were Professor Bain in arts, and Professor Struthers in medicine. Together and singly they fought for reform after reform until to-day the students have almost more than their own and the University adapts itself to every type and variety of man. Struthers by his persistence kept the board of works aware of its obligations to keep the universities in repair. He ultimately got new dissecting-rooms, a new lecture theatre, and a new museum. These, though far from possessing the magnificence of the latest "rooms," ranked as among the best of their time. Attached to the dissecting-rooms was a microscope-room which was an immense innovation. The bone gallery, where in the course of time white bones fell into new orders for the ends of teaching, was not only in itself a well-arranged museum but was also an inviting students' reading-place. The museum was a home of comparative types, the most conspicuous example of which was perhaps the "static procession" of graded skeletons from the minor monkeys, through the higher apes, ourang-outang, and gorilla to man. Nothing could more subtly mould the impressionable mind of the beginner to receive the leading conceptions of comparative anatomy. Partly in the natural order of things, partly—and largely—through the tireless energies of Struthers, the medical school rose steadily in numbers. In a pamphlet published some years ago he records that in 1861–62 the total students of medicine numbered only 160; in 1889–90 (his last year of teaching) they numbered 433. Struthers steadily kept the claims of the school before the general public. The result was that money flowed in, and to-day the medical faculty is assisted by a large number of bursaries, prizes, and at least one good travelling fellowship.

His teaching, both in the dissecting-room and in the lecture-room, was nothing if not objective and demonstrative. He had come through a time when lectures were merely lectures and he set his face against words. The man who did not know his "bones" got no farther forward. He came there to use his own eyes not the eyes of others and use his own eyes he must. In the days of his vigour Professor Struthers was a clear, elegant expositor. To a large extent he used diagrams and blackboard, filling in the outlines as he proceeded. But he put note-taking in the second place. His purpose was to fix in the mind concrete images of things, not verbal descriptions of them. He kept three, if not four, courses running abreast—elementary osteology, general anatomy, regional anatomy, advanced osteology (including comparative), and these had to be verified and supplemented in the dissecting-room. He also had a special course of histology. Like Huxley, he was interested in the "engineering" of the whole animal world. When he went to Aberdeen the "Origin of Species" was only four years old. The new ideas of natural selection, adaptation, and survival were only beginning to affect the few scientific minds that were still young or open. Struthers was open and not yet old. He taught Darwinism as the occasion came and it came often. The "old teleology" came in for many a gentle sarcasm. It is curious how shadowed by theological prejudice physical science seems then to have been; but Struthers, who knew Hugh Miller and the battle he fought, braved the popular opinion and taught to his students what he believed to be the truth.

As in Edinburgh so in Aberdeen Struthers occupied all the time he could in promoting the cause of medical education. He became a member of the Aberdeen Royal Infirmary Board, and at once he urged on the public the necessity for increased hospital accommodation. The fine extensions now in full use owe not a little to his timely forcefulness, and to-day the general public no less than the medical school is the gainer. On his retirement in 1889 he never slackened in the same cause. He became a member of the Edinburgh Infirmary Board and did his powerful best to keep the teaching purposes of the hospital well to the front. It is an open secret that he developed the pathological department immensely. Again, on the Leith Hospital Board he took for years a powerful lead. By urging the exclusion of infectious cases he compelled the local authority to bear its proper burden and lightened the hospital for an increased amount of general medicine and surgery. He succeeded in getting the hospital extended to the necessary dimensions of a good teaching hospital and when the Leith Public Health Hospital at East Pilton was opened two years ago he was there to congratulate the Town Council on the great stride forward.

Meanwhile he had become President of the Royal College of Surgeons of Edinburgh. In 1898 the Queen recognised at once the man and the institution by conferring on him a knighthood. The whole of his pupils and those of the profession who knew him felt that few so well deserved recognition at the hands of the State. Glasgow University had honoured him with the LL.D. degree some years before. His friends had had a fine portrait of him painted by Sir George Reid, P.R.S.A. This beautiful picture now hangs in the new picture gallery of Marischal College. These honours and offices of friendship Sir John Struthers appreciated warmly. But perhaps what touched his heart most was the spontaneous, informal gathering of pupils last July to present him with an address of congratulation on his recent honours.

About a year ago his health began obviously to fail. At the Lister reception in June last his extreme pallor was the remark of everyone. He went on a voyage to Norway, but that was of no avail. He tried the effect of rural scenery, but that also was of no avail. In August or September last he was compelled by weakness to keep his bed. About the middle of February a serious change for the worse came over him and on Feb. 24th after a life of strenuous and unselfish battle for great causes he laid down his arms and passed "to where beyond these voices there is peace."

A member of the General Medical Council writes: "Dr. Struthers, as we all knew him, was a very active member of the Council during the years in which he was a member either for the Joint Universities of Edinburgh and Aberdeen (1883–1886) or for the University of Aberdeen alone (from 1886 to 1891). There was a fighting element in him which found many opportunities of asserting itself. He was always in favour of thoroughness and work in medical education and of such methods of examination as best tested these qualities. He was opposed to the Apothecaries' Council appointing surgical examiners to the Apothecaries'

Society and would have refused such appointments so as to end that corporation in 1887, but was prevented from doing so by a large majority of the Council who thought the society had done good work for the profession since 1858 and that it was somewhat hardly treated by the Royal Colleges under the Act of 1886. His large experience as a teacher in anatomy and his devotion to the work, as well as his native sense and his great knowledge of medical education in Scotland, gave an interest to his speeches in the Council which occasionally, however, were pitched in a tone of superiority which militated against the acceptance of his view. He was for several years chairman of the Education Committee, and in that capacity as well as in that of chairman of the Visitation and Inspection Committees he did very hard and valuable work for which he received the special thanks of the Council in 1891. His love of work, especially of anatomical work, was a passion and continued until illness made it impossible. It infected his pupils and all who came within his influence—a number which included many of the best and most successful members of the profession in and out of Scotland."

CHARLES JOSEPH ARKLE, M.D., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO CHARING-CROSS HOSPITAL.

DR. CHARLES ARKLE whose sudden death Charing-cross Hospital has now to deplore, entered at University College as a medical student in 1879. He qualified in 1884 as a Licentiate of the Society of Apothecaries and in the next year gained the Atkinson Morley Surgical Scholarship. He then proceeded to the M.B. London and subsequently filled the posts of house surgeon, house physician, and obstetric assistant in the University College Hospital. In these posts he won not only the cordial approval of the staff but the warm regard of all with whom he worked. Especially was he popular with his fellow residents in the hospital, for he was in a marked degree genial and kindly, one whom it was impossible not to see was the well-wisher of all with whom he had to do. While his successful career on the junior staff warranted the promotion it was in great part owing to his cordial manner and generous disposition that when the post of senior resident medical officer became vacant he was asked to fill it. It was generally recognised that under him the wheels of the hospital management would run very smoothly—a result which many resident medical officers have found it by no means an easy one to secure. The way in which he carried out the duties of the appointment fully justified all anticipations, and when his appointment as teacher of bacteriology at Charing-cross Hospital and assistant physician to the Brompton Hospital for Consumption, although enlarging his sphere of work, pointed to a severance of his connexion with University College it was universally allowed that the loss would be a great one and that upon Dr. Arkle rested a large share of credit for the present efficiency of the medical school.

In the beginning of 1892 the Council of Charing-cross Hospital decided to combine the posts of pathologist to the hospital and curator of the museum, and Dr. C. J. Arkle was appointed to the office thus created. This was his introduction to the Charing-cross Hospital Medical School and his personality soon made itself felt. He was an able and popular pathologist, grasping the main facts of a case readily and expounding them with remarkable lucidity. His more systematic weekly demonstrations were regularly attended by a large number of students. To the museum he devoted much time and attention, but his work in this department was performed in the recesses of the curator's apartments and did not attract so much attention. At the end of 1892 he was appointed teacher of bacteriology and he held this appointment until last year. In 1895 a vacancy occurred on the medical staff of the hospital and Dr. C. J. Arkle was thereupon appointed assistant physician. This involved the resignation of his former appointment, but as joint lecturer on practical medicine and medical tutor he had ample opportunities for the study and teaching of clinical medicine—the kind of work for which he always showed the greatest preference. Two characteristics in his clinical teaching were very marked. One was an excellent knowledge of surgery and the other was that practical faculty of emphasising essential points which has already been referred to in connexion with his work as pathologist. Dr. Arkle was neither a rapid worker nor a quick speaker, and when to his work already mentioned were added the duties of vice-dean at the medical school and assistant physician at the Brompton Hospital it gradually became evident to some of his friends and, indeed, to himself that even his strong physique might suffer, but he decided not to give up his vice-deanship until the expiration of the ordinary term of office. By a strange and sad coincidence this occurred on the day of his death.

Dr. Arkle was a man who had many friends and no enemies. His genial face, kindly, good-natured disposition, and his interests in sports ensured his popularity among the students, while his sound judgment, his uncompromising integrity, and his varied social qualities made him a favourite with all his colleagues at the different institutions with which he was intimately connected. As a football player he was well known, both when he was a student and for some years afterwards. He was a bold and skilful forward at the Rugby Union game and was captain of the United Hospitals Football Club when that club could place a very dangerous combination in the field. He was an ardent mountaineer and for some years past had been in the habit of devoting at least a month each summer to climbing in Switzerland. He was a member of the Alpine Club and had scaled repeatedly most of the usual peaks of the Alps and many not attempted by the ordinary climber.

Dr. Arkle's contributions to medical literature were fairly numerous and whenever he wrote he always had something to say that was worth saying. Among his most important papers are one contributed in conjunction with Dr. Hinds of Worthing to the Pathological Society in 1896 on Pneumonomycosis, one contributed to the *British Medical Journal* upon the Local Anæsthetic Effects of Cocaine, and one contributed to our columns upon a case of Measles occurring during the Course of Typhoid Fever.

The attack of pneumonia to which he succumbed appeared only three days before death, but it rapidly involved a large extent of both lungs and proved fatal.

ROYAL PORTSMOUTH HOSPITAL.

OPENING OF NEW WARDS.

T.R.H. THE DUKE AND DUCHESS OF YORK visited Portsmouth on the afternoon of Feb. 27th in order to open two blocks of the hospital which have been erected at a cost of £16,000 in commemoration of the Queen's Diamond Jubilee and form the first part of a scheme for the entire reconstruction of the building. There are two wards in each block, measuring 87 feet in length, 28 feet in width, and 14 feet six inches in height. They are lighted by 11 windows on either side and each ward is furnished with beds for 20 patients. The flooring is of Terrazo marble and the heating is by Teale's patent stoves, of which there are two in each ward. A separate block for the bathroom and lavatories has been provided at the end of each building, built of glazed bricks with a connecting passage leading into the ward. Gas is used for cooking purposes and the lighting is by electricity. The plans, prepared by Messrs. Young and Hall of Bloomsbury, show that it is intended in the future to build two other blocks similar in construction. This hospital has previously been favoured with the patronage of the Royal Family. The foundation-stone of the original building was laid by the late Prince Consort on Sept. 27th, 1847, and that of the present new blocks by the Duke of Connaught on August 7th, 1897.

The Duke and Duchess of York travelled from London in the morning and after luncheon at Admiralty House drove to the hospital accompanied by Lord Northbrook and Admiral Sir Michael Culme-Seymour and were received by Sir W. D. King (chairman of the Hospital Committee), the Mayor, General Sir F. Fitzwygram, M.P., Sir John Baker, M.P., General Sir Baker Russell (Commanding the Southern District), Admiral Sir H. Chads, the Bishop of Portsmouth. Proceeding to the board room the following members of the medical staff were presented to Their Royal Highnesses: Dr. Ward Cousins, Dr. Lloyd Owen, Mr. H. Rundle, Dr. Wallace, Dr. Watson, and Dr. Ware. A procession was then formed for one of the new wards where the members of the corporation in their robes and leading representative citizens were assembled. The nursing staff of the hospital lined the corridor. After dedicatory prayers said by the Rev. C. E. CROWLEY, chaplain to the hospital, Sir **WILLIAM KING** opened the formal proceedings by tracing the history of the hospital and describing its growth and various extensions. He claimed that the new part of the hospital was the most perfect of its kind in the south of England.

The **MAYOR** in a brief speech observed that the Duke of Connaught, a soldier, laid the foundation-stone and the Duke of York, a sailor, would open the building, which was most gratifying to a naval and military town like Portsmouth.

Sir **JOHN BAKER** moved a vote of thanks which was seconded by Lord **NORTHBROOK** on behalf of the county and supported by Dr. **WARD COUSINS** who spoke on behalf of the medical staff of the hospital and pointed out the immense advantage that a properly constructed hospital was for the cure of the sick and injured, and expressed his conviction that the other two blocks would be built before long.

The Duke of **YORK**, *in reply, said*: In the name of the Duchess and for myself I cordially thank the speakers for their kind words and for the vote of thanks. I need not say it has given us both the greatest pleasure to come here to-day to take part in the ceremony of opening this new addition to the Portsmouth Hospital. But it gives me a special pleasure because I come here as the member of the third generation of my family who have been connected with this hospital, as the Prince Consort laid the foundation-stone of the original building and the Duke of Connaught laid the foundation-stone of this building in 1897 in commemoration of the sixtieth year of the Queen's reign. I can only say I congratulate you on the completion of these additions which cannot fail to be of the greatest value to the sick and poor of this community, and I wish to commend this hospital to your care and liberality, feeling sure that it will receive at your hands the same consideration in the future that it has always received in the past. I wish the hospital every success and prosperity and I trust that sufficient money will soon be raised to complete the remaining buildings. I have great pleasure in declaring the new wing of the hospital to be open and at the request of the committee I name the two women's wards "Victoria" and "The Duchess of York" and the two men's wards "Albert" and "Connaught."

Afterwards the Royal party inspected the building and partook of tea. On the Duchess being told that one of the survivors of the *Arno* disaster was a patient in the hospital she asked to be taken to his bedside and there she spoke a few words of sympathy to the poor fellow who was deeply touched by the fact that Royalty showed an interest in his welfare.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6900 births and 4505 deaths were registered during the week ending Feb. 25th. The annual rate of mortality in these towns which had been 21·9 and 19·5 per 1000 in the two preceding weeks rose again last week to 20·6. In London the rate was 21·5 per 1000, while it averaged 20·0 in the 32 provincial towns. The lowest rates in these towns were 13·8 in Burnley, 14·1 in Leicester, 15·3 in Portsmouth and in West Ham, and 15·4 in Bristol; the highest rates were 23·3 in Sunderland, 25·8 in Manchester, 26·7 in Liverpool, and 32·0 in Blackburn. The 4505 deaths in these towns included 363 which were referred to the principal zymotic diseases, against 403 and 240 in the two preceding weeks; of these, 100 resulted from diphtheria, 97 from whooping-cough, 69 from measles, 44 from "fever" (principally enteric), 29 from diarrhœa, and 24 from scarlet fever. No death from any of these diseases was recorded last week in Plymouth; in the other towns they caused the lowest death-rates in Leicester, Preston, Huddersfield, and Halifax, and the highest rates in Swansea, Wolverhampton, Birkenhead, and Blackburn. The greatest mortality from measles occurred in West Ham, Bolton, and Manchester; from whooping-cough in Bradford, Birkenhead, and Sunderland; and from "fever" in Wolverhampton and Blackburn. The mortality from scarlet fever showed no marked excess in any of the large towns. The 100 deaths from diphtheria included 29 in London, 12 in Leeds, 11 in Swansea, 9 in Sheffield, 6 in Liverpool, 5 in Blackburn, 4 in West Ham, and 4 in Birmingham. No fatal case of small-pox was registered last week either in London or in any other of the 33 large towns; and two small-pox patients were under treatment in the Metropolitan Asylums Hospitals. The number of scarlet-fever patients in these hospitals and in the London Fever Hospital at the end of last week was 2575, against numbers declining from 2939 to 2587 on the eight preceding Saturdays; 241 new cases were admitted during the week, against 265, 253, and 202 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 481 and 413 in the two preceding weeks, rose again last week to 484, but were 50 below the average. The causes of 59, or 1·3 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Newcastle-upon-Tyne, and in 11 other smaller towns; the largest proportions of uncertified deaths were registered in Wolverhampton, Preston, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 31·2 and 28·0 per 1000 in the two preceding weeks, further declined to 24·1 during the week ending Feb. 25th, but exceeded by 3·5 per 1000 the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 16·0 in Dundee and 21·9 in Aberdeen to 26·8 in Edinburgh and 29·0 in Greenock. The 737 deaths in these towns included 23 which were referred to whooping-cough, 19 to measles, eight to diarrhœa, five to scarlet fever, five to diphtheria, and four to "fever." In all, 64 deaths resulted from these principal zymotic diseases, against 101 and 76 in the two preceding weeks. These 64 deaths were equal to an annual rate of 2·1 per 1000, which was 0·4 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had declined from 43 to 31 in the three preceding weeks, further fell to 23 last week, of which 10 occurred in Edinburgh and nine in Glasgow. The deaths referred to measles, which had been 22 and nine in the two preceding weeks, rose again to 19 last week, of which nine were recorded in Aberdeen, seven in Glasgow, and three in Edinburgh. The five fatal cases of diphtheria exceeded by one the number in the preceding week, and included two in Glasgow. The deaths from scarlet fever, which had been six and 11 in the two preceding weeks, declined to five last week, of which three occurred in Glasgow. The four fatal cases of "fever" showed a further decline from recent weekly numbers and included two in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 346 and 285 in the two preceding weeks, further fell to 233 last week, but exceeded by 116 the number in the corresponding period of last year. The cause of 34, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the three preceding weeks from 31·8 to 27·3 per 1000, rose again to 30·3 during the week ending Feb. 25th. During the past four weeks the rate of mortality in the city has averaged 30·3 per 1000, the rate during the same period being 20·8 in London and 26·8 in Edinburgh. The 203 deaths registered in Dublin during the week under notice showed an increase of 20 upon the number in the preceding week, and included 12 which were referred to the principal zymotic diseases, against eight in each of the two preceding weeks; of these, four resulted from "fever," three from scarlet fever, three from diarrhœa, and two from whooping-cough, but not one either from small-pox, measles, or diphtheria. These 12 deaths were equal to an annual rate of 1·8 per 1000, the zymotic death-rate during the same period being 1·7 in London and 3·0 in Edinburgh. The deaths referred to different forms of "fever," which had been four and two in the two preceding weeks, rose again to four last week. The three fatal cases of scarlet fever exceeded the number recorded in any week since November last. The deaths from whooping-cough, which had been two and four in the two preceding weeks, declined again to two last week. The 203 deaths in Dublin last week included 38 of infants under one year of age and 52 of persons aged upwards of 60 years; the deaths of infants showed an increase, while those of elderly persons were below those recorded in the preceding week. Three inquest cases and three deaths from violence were registered; and 76, or more than a third, of the deaths occurred in public institutions. The causes of 14, or nearly 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

Royal Navy Medical Service.

THE following appointments are notified:—Staff Surgeon W. J. Colbourne to the *Boscawen*, for the *Agincourt*. Surgeons: H. O. Whiteside to the *Boscawen* for the *Dolphin*; S. D. T. Halliday to the *St Vincent*, for the *Martin*; J. M. G. Swainson to the *Boscawen*, for the *Seaflower*; A. A. Forrester to the *Boscawen*, for the *Wanderer*; W. G. Westcott to the *Lion*, for the *Liberty*; F. J McKenna to the *Impregnable*, for the *Nautilus*; J. A. Moon to the *Boscawen*; G. B. Brown to the *Sharpshooter*; H. L. Norris, W. W. Keir, P. H. Bannister, H. W. M Rees, and H. C. Gardner to the *Victory*, for disposal; O. Shepherd, J. Stoddart, E. C. Sawdy, and M. W. Falkner to the *Vivid*, for disposal; J. A. Forrest and R. S. Osborne to the *Wildfire*, for disposal; J. K. Raymond and F. R. Mann to the *Pembroke*, additional, for disposal; and H. Huskisson to the *Cambridge*.

Royal Army Medical Corps.

Lieutenant-Colonel J. A. Clery joins at Woolwich. Major C. E. Nichol is posted to the Station Hospital, Western Heights, Dover, for duty. Major Faunce is held in readiness to embark for Malta. Lieutenant R. E. G. Phillips joins at Woolwich and holds himself in readiness for service in India.

India and the Indian Medical Services.

Captain J. O. Pinto (Madras) is appointed to officiate as Civil Surgeon of Amraoti until further orders. Captain C. G. Spencer, R.A.M.C., and Lieutenant H. J. Walton (Bengal) are placed on special duty under the Government of India in the Home Department. Lieutenant-Colonel T. Grainger, Officiating Civil Surgeon of Champaran, is appointed to act as Civil Surgeon of Darbhanga. The appointment of Major J. Shearer, D.S.O., Bengal Establishment, 27th (Punjab) Regiment of Bengal Infantry, to be Secretary to the Principal Medical Officer, Her Majesty's Forces in India, is confirmed.

The Health of the Navy.

We have already alluded in a summary way to the results embodied in the recently published Statistical Report of the Health of the Navy in 1897 by Sir Henry Norbury, K.C.B., the Director-General of the Royal Naval Medical Service. These results are, speaking generally, very satisfactory. They show that progressive improvement has been taking place of late years and that during the year under review it has not only been maintained but that, as compared with the previous year, and, still more, as compared with the average of the previous 10 years, the aggregate number of cases of disease and injury during 1897 exhibit a decreased ratio per 1000, and that as regards the death-rate that for 1897 is below that of any year since 1856 when the reports first appeared in their present form. The most unfavourable returns are from the West Coast of Africa and are mainly attributable to the Benin Expedition which gave rise to an increased amount of invaliding. The surgeon of the *St. George*, Surgeon Frank H. A. Clayton, gives an excellent article descriptive of the Benin Expedition and of remittent fever, of which his ship had a severe experience—viz., 456 cases. He speaks highly of the value of antipyrin in the initial stage of the fever. The medical officer of the *Widgeon*, Surgeon Charles S. Facey, speaks of the fever on board that ship as of a very severe type. The hæmatozoon of Laveran was found in many of the cases of malarial fever which were under treatment; pigmented spherical bodies were the forms most frequently seen and, in addition to these, crescentic bodies occurred in a few patients but always associated with the spherical variety; amœboid movement was visible in all of them. There is a brief but interesting note in connexion with the *Indefatigable* on the West Indian Station about three cases of poisoning by the manchineel tree—in one case giving rise to vesication of the mouth, lips, and tongue from biting the fruit, and in the cases of two officers to an acute form of ophthalmia from standing under the tree in a shower of rain. The text and figures dealing with Mediterranean fever (newly introduced into the nomenclature) and enteric fever prevalent at Malta and Phalerum Bay are interesting and the whole report for 1897 is well worth reading.

The Annual Report on Army Recruiting.

The medical profession take an interest in common with the rest of the nation in the maintenance of the army and one of the duties of army medical officers brings them a good deal into active connexion with the subject of recruiting. We may therefore briefly allude to some of the results embodied in the annual report of the Inspector-General of Recruiting just issued. The return shows that the total number of recruits enlisted for the regular army during 1898 was 40,729; with the exception of the year 1892, during which 41,659 were raised, this is the largest number of recruits in any year since the introduction of short service. There was a net increase of 9980 men during the year. This increase was not, however, entirely due to recruiting, special inducements having been offered to reservists to rejoin the colours, of which 4479 men availed themselves. A large augmentation in the establishment of the Army was, it will be remembered, authorised during the past year. Although the whole of this increase was included in the Estimates for 1898-99 it was decided that the augmentation should be carried out gradually and spread over a series of years and this is now being done. During the past year an important and, as we think, salutary change was also made in the pay of soldiers and increased facilities for obtaining employment in civil life have been afforded to soldiers after leaving the colours. It is too early yet to feel confident of the continued success of these beneficial measures, but the results so far seem to be very promising.

Whitaker's Naval and Military Directory and Indian Army List, 1899.

As a *multum in parvo* encyclopædia of the names of officers of the three sister services the present issue of this handbook would be hard to beat. For purposes of reference an alphabetical list of officers employed under the Union Jack and the Royal Standard is frequently of great convenience to all those who have anything to do with either or all of the services, and Whitaker's is the only list of the kind with which we are acquainted. The addition of the Indian Army list is a special feature of the present volume and greatly enhances its value.

The late Indian Frontier Campaign.

From the official statistics called for in Parliament by Major Rasch showing the extent of in efficiency among the troops during the Indian frontier campaign of 1897-98 attributable to the results of venereal disease, it appears that the total number rejected, because they were disqualified for field service on that account, was 989 and that 492 were incapacitated during the campaign for the same reason.

Deaths in the Services.

Lieutenant-Colonel Poole Robert Gabbett, R.A.M.C., at Southsea, on Feb. 27th. He entered the Army in 1871 and became Surgeon in 1873. Ten years later he attained the rank of Surgeon-Major and reached that of Lieutenant-Colonel in 1891 and of Brigade-Surgeon-Lieutenant-Colonel in 1895. Until recently he was Principal Medical Officer, Barbadoes.

Queen Charlotte's Lying-in Hospital.—The Earl of Hardwicke presided at the annual meeting of governors of this hospital on Feb 27th. The report stated that during the year 1112 patients had been delivered in the hospital and 1070 at their own homes. The expenditure had amounted to £4123 11*s.* 11*d.* and the ordinary income to £3501 17*s.* 1*d.* The Prince of Wales's Fund had made a grant of £300 to the hospital and £50 to the convalescent home. The enlargement of the hospital was nearing completion and the new nurses' home would be opened about midsummer. The chairman, in moving the adoption of the report and accounts, made an urgent appeal for contributions towards the £7000 still needed for the works at the hospital and the new nurses' home.

Correspondence.

"Audi alteram partem."

MEDICAL CONTRACT WORK IN THE COUNTY OF DURHAM.

To the Editors of THE LANCET.

SIRS,—In the county of Durham we are in the midst of a struggle to obtain a higher rate of pay from the miners of the collieries; in some parts we have succeeded beyond expectation, some are wavering, and some are in direct opposition to the change. With patience and gentle forbearance we shall get all to agree to the increase. Our present danger is from those of our own profession who may step in and accept the old terms. I ask for your powerful aid in preventing any such occurrence. Members of the Medical Union are working shoulder to shoulder and will stoutly resist the invasion of strangers, and those of our number who may suffer loss from temporary suspension of pay will be assisted by their more fortunate brethren.

I am, Sirs, yours faithfully,

EDWARD JEPSON,

Durham, Feb. 27th, 1899. President of the Durham Medical Union.

*** Our correspondent will find that we have on more than one occasion urged upon the profession the necessity of supporting one another in this movement and similar movements. We trust that no medical man will be so blind to the interests of the profession which he has joined (and therefore in the long run to his own interests) as to accept lower terms from the miners of Durham than those which the present members of the Durham Medical Union are justly asking.—ED. L.

YERSIN'S PLAGUE SERUM.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Jan. 21st your special correspondent in India states in connexion with my evidence before the Indian Plague Commission that I "had nothing conclusive to say from personal experience" as to the value of Yersin's serum. Will you allow me to state that, on the contrary, I was able from personal experience to give a very definite opinion as to the value of this form of treatment in plague? That conclusion was, I regret to say, unfavourable to the claims of the serum. It was based upon a carefully conducted trial in which 50 cases of plague were submitted to the serum treatment and 50 other cases in the wards at the same time were noted as control cases. As the mortality in each group of cases was the same (60 per cent.) and as there was no perceptible effect whatever upon any of the symptoms I was forced to the conclusion that Yersin's serum is an entirely indifferent substance in the treatment of plague without influence for good or evil upon the course of the disease. I hope shortly to publish notes of the cases.

I am, Sirs, yours faithfully,

Calcutta, Feb. 8th, 1899. FRANK G. CLEMOW.

"REGINA *v.* REICHARDT."

To the Editors of THE LANCET.

SIRS,—If Mr. Sers will turn to the Lunacy Acts he will see that a lunatic is defined as an idiot or a person of unsound mind, and that medical certificates of insanity must state that the person affected is a lunatic, an idiot, or a person of unsound mind. The Scottish Acts, however, permit in addition the use of the term "an insane person." There is therefore no need to differentiate between the phrases "temporary unsoundness of mind" and "temporary insanity." It is of no importance from a legal point of view. Delirium tremens and the delirium of typhoid fever are both manifestations of temporary insanity and persons of unsound mind owing to these toxæmic disorders have occasionally been certified to be insane. That is not of frequent occurrence, for the medical profession is educated to foresee that the mental trouble is temporary and consequent on a physical state which can be corrected without resort to asylum care and treatment. There are no doubt other causes of temporary insanity, causes more obscure and less definite in prognosis, but they are not so difficult to discover by those experienced in these maladies as to require the formidable and complicated legal procedure which has been imposed on the English public.

The question at issue is whether every person who is insane from the medical standpoint should be swept into the asylums of the country or be placed under medical certificates such as at present are in use. Is he "a proper person to be detained under care and treatment and in a fit condition of bodily health to be removed to an asylum"? These are the words of the schedule. The answer must be emphatically "No." It is well known to those directly interested in the treatment of the insane that efforts are being made to avoid the manifest evils of the present system, by introducing into the English law a provision which has long existed in Scotland, whereby those afflicted by temporary insanity can be placed under suitable private care upon the certificate of the medical attendant to the effect that the malady is not confirmed and that such treatment is necessary for a period not exceeding six months. This should have the hearty support of the medical profession in the interests of the insane. Mr. Sers entirely misses the central point of the case in suggesting that Dr. Reichardt assumed a responsibility which he was not called upon to assume. On the contrary, he fortified himself behind the authoritative opinions of Dr. Savage, Dr. Goodhart, and Mr. Kingsford. No evidence in the opposite sense, of similar weight, was adduced by the Commissioners who of course acted on the law as it stands. We may assume that they are well aware of the unsatisfactory results of the present Act which threaten to become worse in time unless remedies are applied. Yet such are the operations of the law that Dr. Reichardt after technically winning his case finds himself most severely fined. Surely there is something much amiss leading to such a fiasco. One calls to mind Mr. Anderson's hard lot when the jury awarded him heavy damages and the Chief Justice of England immediately informed him that he was not permitted to give effect to their verdict.

I urge that the medical profession should fully recognise that not every case of insanity should be sent to an asylum, that the limitations of the present law are prejudicial to the insane and to those who are bound to serve them, and that relief must be sought from the present impasse.

I am, Sirs, yours faithfully,

Feb. 18th, 1899. AN ASYLUM PHYSICIAN.

P.S.—Since the foregoing letter was written the Lord Chancellor has indicated a favourable opinion regarding the principle of the proposed clause in reference to incipient insanity, on the representations made by a joint committee of the British Medical and Medico-Psychological Associations on Feb. 22nd.

INTRAVENOUS INJECTIONS IN SYPHILIS.

To the Editors of THE LANCET.

SIRS,—I was much interested to see the results of intravenous injections of cyanide of mercury in syphilis published by Mr. Chopping in THE LANCET of Feb. 18th. It, however, does not appear to me that these results maintain the advantages claimed for this method of treatment. The advantages claimed are: (1) as the injection is made daily the patient is under constant observation; (2) the exact quantity of mercury introduced into the system is known; (3) the patient is brought more rapidly under the influence of mercury than by other methods; (4) serious lesions clear up more rapidly; and (5) this treatment is useful where other methods fail. The last of these claims is the only one apparently above criticism. With regard to the others: (1) daily injection is irksome and inconvenient both to the patient and the operator and requires many more injections than are given in the intra-muscular method; (2) the "exact quantity of mercury introduced into the system" is not the point in question, which is rather the effect produced on the patient by mercury under any method of administration, and this can only be judged by its effects, not by any method of measuring quantities; and (4) as to grave lesions clearing up more quickly under this treatment, this might be claimed for other methods, for those who have dealt much with syphilis know that similar lesions in different patients vary considerably in their rapidity of disappearance and often yield to one method of treatment after resisting another. The average duration of treatment in Mr. Chopping's cases was just over 23 days, by which I understand the disappearance or healing of the lesions present at the time treatment was begun. From my experience at the Lock Hospital with inunction of mercury I should put the average at about 21 days for primary and secondary cases. With regard to tertiary cases I notice that iodides were given in all Mr. Chopping's cases and therefore the effect produced by the intravenous injection cannot be estimated. The average time for symptoms to disappear under the treatment by pills is, I believe, not more than 21 days. It therefore appears that the intravenous treatment has no advantages over treatment by pills or inunction although it may have an advantage over intra-muscular injection which is painful and, as far as my experience goes, requires a rather longer time for disappearance of symptoms.

I am, Sirs, yours faithfully,
C. F. MARSHALL, M.D. Vict., F.R.C.S. Eng.
Finsbury-square, E.C., Feb 23rd, 1899.

"A FATAL CASE OF LITHÆMIC POISONING."

To the Editors of THE LANCET.

SIRS,—I desire while thanking Dr. Elgood for his very interesting paper in THE LANCET of Feb. 18th to point out to him that he will find a case which presents many symptoms in common with that which he relates on p. 439 of the fourth edition of my work on Uric Acid. The more important of these signs are the gastric disturbance, the high tension pulse, the enlargement of the liver, and the scanty urine; and he will also find that the relation to these of epistaxis, thrombosis, anæmia, and prostration and the final ending in coma are fully considered and illustrated by other cases. The attacks of gout are most interesting and the fact that these came between the attacks of lithæmia while the thromboses came in the attacks almost amounts to a demonstration of my explanation of causation. My patient recovered and has obtained freedom from his attacks as the result of altering his diet; and Dr. Tomson of Luton, whose patient he was, writing to me in February, 1896, some three years after I first saw him, says that he "has not had one of his attacks for more than a year."

I therefore most strongly agree with Dr. Elgood that the case he records is one of poisoning due to lithæmia or, as I have called it, collæmia. The fact which will appear when the whole of my researches have been published is that uric acid controls so completely the circulation of the blood that any accurate measurement of that circulation is a measure also of the quantity of uric acid in the blood and urine and corresponds in every way to this.

I shall presently be able to demonstrate methods by which any third-year student can estimate with considerable accuracy a greater or less quantity of uric acid in the blood or urine and tell almost without instruments and in one or two minutes of time the chief diurnal fluctuations and the pathological alterations of these; and no doubt these methods would have shown very clearly the fluctuations with and between the attacks in Dr. Elgood's case on the careful observation of which I beg to congratulate him.

I am, Sirs, yours faithfully,
ALEXANDER HAIG, M.D. Oxon.
Brook-street, W, Feb. 24th, 1899.

HUNTER *v.* CLARE.

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent, Mr. J. B. Pike, I beg to enclose a copy of a letter from the clerk to the Society of Apothecaries sent in answer to a query of mine as to whether I was, as an L.S.A.—qualified since 1887—entitled to call myself a "surgeon," the query being a consequence of the decision in "Hunter *v.* Clare." I quite agree with the decision of the court and have always considered the use of the word "physician" as bad form in a general practitioner. As I understand the word a physician prescribes for a fee but does not dispense. Webster's Dictionary defines a surgeon as "one whose profession is to cure external diseases whether by manual operation or by medication—externally or internally." The word "apothecary" would be used by the public of to-day as synonymous with "chemist." If the General Medical Council felt the same with regard to the use of the word "surgeon" as "physician," why did they not proceed with that portion of the indictment? I might remind you that the triple L.S.A. entitles its holder to compete for the post of *surgeon* in the army or navy. I should be glad to know your opinion as to the use of the word "surgeon" by an L.S.A. qualified to practise surgery. I am, Sirs, yours faithfully,

C. MONTAGUE LEAKEY.
Tower House, Caistor, Lincs, Feb. 6th, 1899.

[INCLOSURE.]

14, Austin Friars, London, E.C., Jan. 27th, 1899.

DEAR SIR,—The decision of the court in Hunter *v.* Clare does not go further than to lay down the rule that Licentiates of the Society are not entitled to style themselves "Physician." Their position as to the user of the word "Surgeon," in my opinion, remains as before.

Yours truly,
JAMES R. UPTON,
Clerk to the Society of Apothecaries.
C. M. Leakey, Esq, Caistor.

"DIFFICULTIES UNDER THE NEW VACCINATION ACT."

To the Editors of THE LANCET.

SIRS,—I also am a Public Vaccinator and see no cause to be ashamed of the position, as your correspondent "P. P." thinks we all ought to be. For my part I am as keen about the ethics of the profession as the next man and so are all my colleagues I have not the slightest doubt. "P. P.'s" letter strikes me as being altogether silly. It does not ring with a true note. For instance, he says, "If a public vaccinator may call on people of whom he knows nothing except that they have a child unvaccinated and offer his professional services, then I may call at any house where I hear there is measles and offer my professional services." Cannot "P. P." distinguish between the man who is doing his duty under Act of Parliament and the "cadger" (his own expression) unauthorised by anyone trying to force himself in where he is not wanted?

Private practitioners have the game in their own hands—they have simply to take care that all their cases are vaccinated or accounted for to the vaccination officer before they are four months old. 90 per cent. of mothers are glad to get the job over long before that if they mean having it done at all.

I am, Sirs, your obedient servant,
THOS. FREDK. I. BLAKER,
Feb 23th, 1899. Public Vaccinator Preston and Patcham, Sussex.

To the Editors of THE LANCET.

SIRS,—Your correspondents, "L.R.C.P., M.R.C.S.," and "P P.," in THE LANCET of Feb. 18th and 25th respectively, before writing of fellow practitioners as they do should make themselves acquainted with the subject in question and not show such ignorance as especially your first correspondent does. In my opinion there is nothing interfering with professional etiquette in the new Act, for if the law is complied with the public vaccinator exceeds his duties if he calls on any fellow practitioner's patients. The Act says, if the vaccination is not performed within a certain time or reasonable excuse is sent to the vaccination officer, he, the vaccination officer, shall notify the public vaccinator in due form, whose duty it shall be to send in a notice to the parent or person having custody of the child in question giving at least 24 hours' notice of his intention to come and offer to vaccinate. In addition at the foot of this notice, which is known as Form I (copy enclosed), there is a space for the address of the public vaccinator. Now, why is 24 hours' notice given and why is this space left at the foot of the notice? The only reason I can put forward is, so that the receiver may communicate his or her desire as regards the call to the public vaccinator, and may inform him that the family medical man was going to do the operation or was about to postpone it. I presume that would be "sufficient reason for delay" (see General Order, Oct. 18th, 1898, page 7) and the public vaccinator should not call then and may not have to at all.

Your first correspondent writes: "I consider the action of the public vacci

May I say that my opinion of your correspondent's letter is still worse; and if he shows such ignorance over an Act related so closely to his professional work after all this time it is not unlikely that he is equally ignorant in other branches of his profession, which failing may shed a new light on his jealousy of the public vaccinator in his district. Your correspondent "P. P." says, "The public vaccinator accepts the work for the sake of the pay and I might call on a case of measles for a similar reason." The analogy is absurd. Further, he wishes public vaccinators all sorts of trouble.

Both these letters are very unfair and they show gross ignorance of an Act which it is the duty of every practitioner to know. Because your correspondents' patients and themselves do not comply with the law they try to make the public vaccinators answerable. It would be about equally unfair for a solicitor to abuse a policeman for arresting a burglar who happened to be his client, or for a private schoolmaster to rail against a board schoolmaster because he happened to teach children above the general poor, if analogies are required.

I am, Sirs, yours faithfully,

Feb. 27th, 1899. FAIRPLAY.

THE BATTLE OF THE CLUBS.[1]

(FROM OUR SPECIAL COMMISSIONER.)

WESTON-SUPER-MARE.

The Formation of a Provident Dispensary at the Hospital and of a Provident Medical Association by the Medical Practitioners of the Town.

To understand the position of the medical practitioners at Weston-super-Mare it is necessary to realise how rapidly the town has sprung into existence. It is stated that in 1811 this town was but a small fishing village with 163 inhabitants. An Act of Parliament was then obtained by the local landlords and various improvements were effected. In 1828 a village of 250 houses with a population of 1500 inhabitants had come into existence. In 1851 there were 655 houses and 4033 inhabitants. The question of medical care for the poorer section of this population now became urgent and in 1857 a dispensary organised on a charitable basis was established; but the population went on increasing by leaps and bounds. In 1871 it had multiplied to 10,564, and the dispensary had already grown into a hospital. During the first two years, 1866 and 1867, the hospital had only seven beds; but during the next two years it had 16 and 17 beds respectively. After that for eight years there were 20 beds, and as the number of in-patients soon exceeded 200 per annum the number of beds was increased to 32 in 1879, and there are now 35. The population amounted to 12,872 in 1881, and it now exceeds 20,000. During these years there was a corresponding growth in the number of out-patients who attended the hospital. In 1866, the first year of the existence of the hospital, there were 923 out-patients. In 1876, the number had doubled—i.e., 1832. The maximum was reached in 1879 when there were 2968 out-patients. As the house surgeon had to go to see such patients as could not be admitted into the hospital and were too ill to attend as out-patients it soon became evident that he was overworked. It was then suggested that if a provident dispensary was organised in connexion with the hospital the services of another house surgeon could be engaged and the pressure on the hospital would thus be relieved. The idea was good in principle, but in those days no one had any experience of the evils which might arise. It was on July 1st, 1886, that the provident dispensary was opened. The services of a second resident surgeon were engaged. He is provided with free quarters at the hospital and receives a salary of £87 6*s.* 9*d.* per annum.

The hospital dispensary serves for the members of the provident dispensary and the committee which manages the hospital likewise manages the dispensary. Here, then, and from the very commencement, is a fundamental error. This committee is elected by the subscribers and donors to the hospital; the committee which manages the provident dispensary should be elected by those who by their work or their money maintain the dispensary. How can a committee of the subscribers to the hospital claim a right to decide how the pennies paid each week to the provident dispensary shall be spent? It may be said that the hospital helped the provident dispensary, but in that case the hospital committee have only the right to claim a share in the management of the dispensary, which shall be in proportion to the help which they have given. Now, the accounts for the year 1897 show that the receipts due to the weekly penny payments received from the members amounted to £335. Entrance fees swelled the total to £356. The expenses did not equal this amount and there was a balance of £179 19*s.* 1*d.*, which, however, was not kept for the benefit of the provident dispensary but handed over to the credit of the hospital general account, so that to-day it is not the hospital that is helping the dispensary but it is the dispensary that is handing over hard cash to the hospital, and yet the hospital committee claim the right to govern the dispensary. It is true that the hospital management is careful to explain that this sum of £180 is not all profit. They state that the maintenance of the medical officer specially appointed to attend upon the members, and who resides in the hospital, is paid out of the general fund and the cost of the drugs and so forth dispensed to the members is defrayed from the same source in the first instance, so that the hospital has to be reimbursed for these charges before any question of profit can arise. On looking into the details of the accounts, however, it will be found that out of the dispensary funds the medical officer's salary is paid, and £20 are given to the dispensary. From the balance of (in round figures £180) the hospital has the right to claim rent for the premises occupied and for the drugs dispensed. But even if a liberal allowance be made for this a profit would still remain. The medical officer of the provident dispensary by his work and the members by their subscriptions have produced an income which exceeds the expenditure. Is it right that they should be made to hand over all the net profits that arise to the hospital without being able to have a voice in the matter?

The hospital authorities say that it is not possible to apportion the cost of the drugs between the in- and out-patients attending with subscribers' notes and the provident dispensary members. Yet the average cost of the treatment of each patient is well known and the number of patients who are hospital patients and of those who are dispensary patients is likewise easy to ascertain. The computation which would be made might not be mathematically exact, but in any case it would be more correct than the present simple but arbitrary process of pocketing all the profits. At all events, those who create these profits ought to have a voice in their disposal. The hospital medical staff have the right to sit *ex officio* on the management committee but they have a right to only three votes. As the lay members of this committee number 15 members the medical staff, though they do the greater part of the work, are absolutely outnumbered. It should be one of the objects of the association formed by the medical men practising at Weston-super-Mare to increase their voting power on the general committee of the hospital. These criticisms, however, must be taken as purely theoretical. I have not heard any complaints as to the hospital management. On the contrary, one or two medical men whom I have questioned on the matter have assured me that they thought that the hospital committee managed affairs "fairly well." It was also pointed out to me that the medical officer of the provident dispensary derives some advantage from the fact that he resides at the hospital. Though it is his duty to attend first and foremost to the dispensary subscribers still he is able in his leisure moments to see the hospital patients, to attend at operations, and thus to increase his general experience.

The creation of a dispensary in connexion with the hospital has led to an important revelation. There are no complaints as to abuse. The town is small, the respective positions of its various inhabitants are known, and it would be difficult for anyone to present himself at the hospital under false pretences. Yet though nearly all the patients were poor it soon became evident that the majority could have paid something and that they had no desire to be the recipients of charity. The maximum number of out-patients seen was 2968 in the year 1879. Since that date there has been a steady decrease to 2702 in 1880, 2009 in 1884, and 1898 in 1885. The number in 1886 was 1688 and the

---

A reprint of the previous articles on the above subject has been published in book form entitled "The Battle of the Clubs," and can be obtained from THE LANCET Offices; price 1*s.*

provident dispensary had been started on July 1st of that year. That the decrease of out-patients is due to this fact is proved by the figures of the following year when there were only 795 out-patients. In the year following the number was 812, then it fell to 702 in 1889, to 595 in 1890, and in 1897 it was only 552. If we take the average of the last five years the number of out-patients at the hospital was 585 per annum. If, on the other hand, we take the average for the five years preceding the creation of the provident dispensary the number of out-patients was 2230 per annum. Thus it may be said roughly that not only were close upon three-quarters of the out-patients in a position to pay a small subscription, but that they actually did pay such a subscription when the opportunity was afforded them to do so.

These figures are most interesting, particularly as there is no special reason to believe that they apply only to Weston-super-Mare. The same experiment tried elsewhere might bring about similar results. Indeed, the success of the Saturday Hospital Fund in so many towns is a different manifestation of the same spirit which has led the poorer classes of Weston-super-Mare to financially support the hospital provident dispensary. These facts unfortunately have been better analysed and appreciated by speculative financial companies who build up fortunes by the wholesale collection of pennies from the poor than by the members of the medical profession. Thus the Liverpool and Victoria Legal Friendly Society sent its agents to canvass the town. All who would ensure their lives at the rate of a penny or more per week obtained on the payment of another penny medical aid when sick. This insurance company brought down medical officers of its own to Weston-super-Mare and its collectors and agents touted for these new-comers to the detriment of the old-established practitioners and to the degradation of the profession. The whole series of well-known abuses followed in due course. There was no wage limit. The medical men employed were sweated and if they complained new men were brought into the town. One practitioner employed by this insurance company had to attend a patient once every week for six months though he lived at a distance of four miles. During the last week the patient had to be seen every day at his distant home. Nevertheless, this patient only paid 4*s*. 4*d*. per annum, out of which the medical attendant received only 3*s*. and had to provide at his own cost all the medicines required.

In the face of these grievances which had lasted a few years and were becoming more and more acute the local practitioners determined to take action. The first meeting for this purpose was convoked on July 24th, 1896, and of 18 available medical men 10 attended. Those who were not present had been detained by patients and through other causes and were not absent through any feeling of indifference or hostility to the movement. On the contrary, the greatest unanimity prevailed from the very first and there was not any of that rivalry as to leadership which has marred similar movements in other towns. Nor did the hospital staff stand aloof; they, on the contrary, took an active part in what was being done. The resolution carried at the first meeting by the 10 medical men present was sent round and was signed by seven others who had not been present. The terms of the resolution agreed upon were as follows:—

> We, the undersigned medical practitioners of Weston-super-Mare, having duly considered the position of the Medical Aid Association and having obtained advice from medical men elsewhere who are best acquainted with similar associations, hereby agree to decline (1) to meet in consultation any medical man connected with medical aid and similar associations; (2) to assist him in operating or in administering anæsthetics; (3) to meet him in consultation upon patients other than those of the association, and (4) to have any professional intercourse with him. In the interests of humanity, however, we do not refuse our advice and assistance to members of the association or to other patients of the association's medical officer on the condition that he previously retires from the case.

There was another clause to the effect that this did not apply to *bonâ fide* working men's benefit societies such as the Oddfellows, &c. This, however, in itself did not suffice. It soon became evident that the insurance companies could only be fought by giving the public the option of something else organised on better lines. Therefore it was ultimately decided that the medical men should organise a medical provident association of their own and this was no easy matter. A sub-committee was appointed to work out a scheme and they had to meet over and over again to discuss the details. But at last a workable plan was adopted together with a suitable set of rules.

Weston-super-Mare, Feb. 27th.

(*To be continued.*)

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Inquests held by the Coroner of Liverpool in 1898.

DURING the year 1898 1632 cases of death were reported to, and investigated by, the coroner for Liverpool. Inquests were deemed unnecessary in 655 of these cases. Inquests were held on the bodies of 600 males and 377 females, making a total of 977, the sex, ages, and legitimacy or otherwise being accounted for as follows. Infants (legitimate) under one year, 90 males and 76 females; of one year and under seven years, 61 males and 39 females. Infants (illegitimate) under one year, nine males and five females; of one year and under seven years, two females. Children of seven years and under 16 years, 31 males and 17 females. Youths of 16 years and under 25 years, 29 males and six females. Adults of 25 years and under 60 years, 306 males and 177 females. Aged 60 years and above there were 74 males and 55 females. Post-mortem examinations were made by order of the coroner in 84 cases. Accidents accounted for the deaths of 245 males and 152 females. 75 males and 53 females were suffocated whilst in bed with parents or otherwise. 107 males and 82 females died from excessive drinking. 41 males and 12 females committed suicide while insane. Verdicts of murder were returned in four cases (females) and of manslaughter in four cases (males). 18 males and four females were found drowned. Want and exposure to cold accounted for two male deaths. 63 males and 43 females died from natural causes. Five males and two females were stillborn. Five males and eight females died from want of attention at birth. Inquests were held on the bodies of 11 male and 15 female newly-born children.

Closure of the Liverpool Lock Hospital: Opening of an Out-patient Department.

On the plea of insufficiency of funds the committee of the Liverpool Royal Infirmary have decided to close the Lock Hospital as regards the reception of in-patients early in March. It has been arranged to carry on the institution as an out-patient department of the Royal Infirmary. It is hoped that the students of University College will in this manner still be afforded the opportunities hitherto enjoyed by them for the clinical study of syphilis and other special diseases. It may be mentioned in this connexion that the Royal Infirmary and the other general hospitals in the city refuse admission to patients suffering from venereal affections, so that in future the workhouse will be the only refuge for the respectable poor who have contracted syphilis not through their own misconduct. Everyone is aware of the ravages of syphilis in its later manifestations, especially in neglected cases. An analysis of cases treated in the medical wards of general hospitals shows that a large proportion of nervous and allied diseases have had their origin from this source. It would be a wiser and a more humane policy for the general hospitals to afford facilities for the admission as in-patients of those suffering from syphilis in its early stages when it is fairly amenable to treatment than to await the period when the diagnosis shall have become obscured and the disease, in a majority of cases, shall have reached a stage which resists treatment. The example set by hospitals like St. Thomas's, St. Bartholomew's, the London Hospital, the Middlesex Hospital, the Edinburgh Royal Infirmary, &c., where these cases are admitted, might with benefit be imitated by hospitals of less repute. In the January number of the *Liverpool Medico-Chirurgical Journal* will be found an interesting communication from the pen of Mr. F. W. Lowndes on the Study and Treatment of Venereal Diseases, especially Syphilis, in which the whole subject of lock hospitals and lock wards in general hospitals is treated in an able and exhaustive manner. In alluding to the Liverpool Lock Hospital he states that it provides the only accommodation in Liverpool for males and females suffering from primary syphilis, severe cases of gonorrhœa with its complications of bubo, swelled testicle, &c. It has received in the past many English and foreign seamen of all nationalities, to whom it has been of the greatest service, not only curing their diseases but making them seaworthy and able to gain their living. It has afforded relief to many married women and children who have been infected with loathsome diseases through no fault of their own; and he asks in all earnestness, Could there be more deserving objects of the charity of the benevolent? The Royal Infirmary, as a teaching hospital intimately connected with University College, ought to provide some beds for the reception of patients suffering from severe forms of early syphilis. If it cannot afford to maintain the Lock Hospital as a separate establishment some means can surely be found whereby a few beds could be set apart for that purpose in the infirmary, following the examples of the London and Edinburgh hospitals mentioned above. It provides a few beds for ophthalmological cases, and very properly so, but it is difficult to understand how syphilitic iritis or retinitis occurring in patients who have acquired disease through their own misconduct should receive more consideration than syphilitic manifestations on other parts of the body which may have been acquired through no fault of unfortunate sufferers, such as glassblowers, midwives, married women, and others. There is a strong feeling, not confined to members of the medical profession, that the closure of the Liverpool Lock Hospital is a mistake and the fact is received with surprise and incredulity by those who hear of it for the first time.

Liverpool Stanley Hospital: Grave Financial Condition.

The financial outlook of the Stanley Hospital is unfortunately in a very critical condition. A tone of despondency prevailed amongst all the speakers at the recent annual meeting. The hospital is situated in the north end of the city, and is in proximity to the docks where accidents are of frequent occurrence. It consequently does a large amount of useful work. Last year 662 surgical cases were admitted to the hospital as in-patients. The out-patient department is a large one; no less than 8604 surgical cases and 4898 medical cases were attended to during the year 1898. The total attendances, including special cases, reached the total of 17,686. It is a question whether the increasing deficit, which at the end of the year had reached the sum of £1865 7*s.* 3*d.*, may not eventually result in the closing of the hospital. The ordinary income for the year, including £369 7*s.* 4*d.* from entertainments and a special church collection, amounted to only £2835 11*s.* 7*d.*, and the ordinary expenditure exceeded that amount by £860 11*s.* The subscription list is limited to 548 individuals who are mostly in affluent circumstances; whereas the general public hold back their assistance, whether by reason of indifference or from the pressure of the local rates, which are now very burdensome and are likely to increase rather than diminish, is a moot point. The Stanley Hospital has had a very creditable record as regards its medical staff, five of whom are now on the staff of the Royal Infirmary, comprising two surgeons, one physician, and two assistant physicians.

Liverpool Eye and Ear Infirmary: Annual Report.

The financial position of the Eye and Ear Infirmary opened at the beginning of 1898 with a credit balance of £112 8*s.* 10*d.*, but it closed with a debit balance of £368 12*s.* 1*d.* The reduction of income was due to the falling off in donations and legacies. For the first time for many years not a single legacy had been received, whilst the donations were £51 4*s.*, as against £261 5*s.* 6*d.* in 1897. The sum of £480 was received from the Hospital Sunday and Saturday Fund. The report states that 6149 new eye cases and 2121 new ear cases had been treated during the past year in the out-patient department. The number of minor operations on out-patients was 1147. 709 patients had occupied beds in the infirmary and the number of important operations in this department was 576. Mr. H. H. Hornby has resigned the position of honorary treasurer, which he had held for 25 years.

The Guardians of Liverpool and the Treatment of Tuberculosis.

At a conference of Poor-law guardians representing the three large unions of Liverpool held in the board-room of the West Derby Union it was unanimously decided to make an effort to treat cases of tuberculosis amongst the poor, and in furtherance of this view it was agreed to erect a sanatorium in some suitable locality for the treatment of early cases. This is the first instance in which Poor-law guardians have taken such a generous and enlightened view with regard to the subject of tuberculosis, and it is to be sincerely hoped that the good example will be followed by other boards of guardians throughout the country. A complete scheme has been drawn up by Dr. Nathan Raw, medical superintendent of Mill-road Infirmary, which has regard to the treatment of early cases in sanatoria and the isolation of chronic or hopeless cases in separate wards of Poor-law infirmaries, together with the necessary precautions to prevent the spread of the disease.

Bequests to Liverpool Hospitals.

The Royal Infirmary has received £1000 and the Royal Southern Hospital, the Northern Hospital, the Stanley Hospital, the Bootle Borough Hospital, the Infirmary for Children, and the Outdoor Maternity Charity, Brownlow-hill, £500 each, the bequests of the late Miss Mary Anne Macneilledge of Liverpool.

Liverpool Northern Hospital.

Mr. R. W. Murray, F.R.C.S. Eng., honorary surgeon to the Liverpool Infirmary for Children, has been appointed honorary surgeon to the Northern Hospital in the room of the late Mr. Arthur H. Wilson.

The School of Tropical Diseases.

A meeting of the committee of the Liverpool Association of Foreign Consuls was held on Feb. 27th in the office of the Brazilian Consulate for the purpose of taking into consideration the Liverpool School of Tropical Diseases and its recognition by the Governments of the various consuls. The company having been addressed by Mr. Alfred L. Jones, as representing the Congo Free State, and by Mr. Ehrenberg, consul for Sweden and Norway, it was agreed to hold a general meeting of the consuls on March 9th so that they might be better able to inform their Governments on the subject. Professor Boyce then explained that four courses of two months each would be given to qualified men every year. Liverpool, he thought, was the best possible place in which to establish such a school, as they had examples of the diseases in question brought from all the tropical regions of the world. Besides instructing qualified medical men who would have appointments on shipboard or intended to practise in tropical countries they would admit missionaries to the classes and would also train black women as nurses.

Feb. 28th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Retirement of Dr. John Sibbald, Commissioner in Lunacy.

DR. JOHN SIBBALD, who has filled the office of Commissioner in Lunacy for 21 years, will retire under the age limit at the end of March. In Dr. Sibbald's case there has been a nine months' extension of his period of service. Dr. Sibbald was educated at Edinburgh University and took the degree of M.D. in 1854. In connexion with asylum work he has filled various posts. For some years after graduation he was an assistant physician in the Edinburgh Royal Asylum. In 1862 he was appointed superintendent of the Argyll District Asylum and in 1870 he was made a Deputy Commissioner in Lunacy. He received his present appointment in 1878. Dr. Sibbald was co-editor of the *Journal of Mental Science* from 1870 to 1872 and in 1877 he was the Morison lecturer on Insanity to the Royal College of Physicians of Edinburgh. Among his literary contributions may be mentioned "Clinical Instruction on Insanity," "Gheel and Cottage Asylums," "Lunacy Administration in Berlin and in Scotland," and "Plans of Modern Asylums." In "Plans of Modern Asylums" Dr. Sibbald gives a full account of the Alb-Scherbitz Asylum in Prussian Saxony which has led to the adoption of similar plans for the new hospital for Edinburgh at Bangour. As a Commissioner in Lunacy Dr. Sibbald has done much to improve the condition of the insane in asylums and private institutions and has won the respect and confidence of superintendents of asylums throughout the country.

Edinburgh New Town Dispensary.

At the annual meeting in connexion with the Thistle-street dispensary held on Feb. 23rd the medical officers' report stated that 8164 cases had been dealt with at the dispensary and of these 764 patients had been seen in their own homes. The institution had recently lost many friends through death and the subscriptions were less than they had been in the previous year. The expenditure, however, had also been less and there had been an increase in the legacies.

Funeral of Professor Rutherford of Edinburgh University.

On Feb. 25th Professor Rutherford's body was conveyed from his residence, at Douglas-crescent, Edinburgh, by rail to Belses Station and thence by road to Ancrum Churchyard. A large number of the University professors and students were present at the service which was conducted in his house at 9 A.M. by the Rev. Dr. Scott of St. George's. A number of beautiful wreaths were sent, among them being wreaths from Sir William Muir, from the present members of the late Professor Rutherford's class, from former assistants, from members of the South African Students' Union, from the Students' Representative Council, from the past and present University lecturers, from the members of the Australasian Club, from the assistants and research workers in the Physiological Laboratory, and from the residents of the Royal Infirmary. After the arrival of the train at Belses the coffin was carried shoulder high from the carriage to the hearse by members of the late Professor Rutherford's class and of the Students' Representative Council. When the churchyard was reached the coffin was again carried by students from the churchyard gate to the grave. Among the pall-bearers were Professor Simpson, representing the Royal College of Physicians and the University of Edinburgh; Dr. Carlier, assistant to the late Professor Rutherford; Mr. Carnegie Dickson, representing the students; Dr. Rutherford of Kelso, and several other relatives; Professor Stirling, Owens College, Manchester; and Professor de Burgh Birch, Yorkshire College, Leeds. Former assistants of the Professor were also present at the interment.

Royal Edinburgh Asylum for the Insane.

The annual meeting of the Corporation of the Royal Edinburgh Asylum was held on Feb. 27th. From the report of the managers it appeared that the average daily number of patients under treatment showed an increase of 23 on the numbers for last year. The ordinary revenue amounted to £53,362 6*s.* 5*d.* and the ordinary expenditure, including interest, to £48,951 11*s.* 7*d.*, leaving a surplus revenue of £4410 14*s.* 10*d.* From this surplus the annual instalment towards liquidation of the West House debt, amounting to £1727 4*s.* 7*d.*, had to be subtracted, leaving a free surplus of £2683 10*s.* 3*d.* The surplus derived from Craig House was greater by £1413 9*s.* 6*d.* than the surplus in 1897. The surplus derived from intermediate patients exceeded what it was in 1897 by £9 18*s.* 11*d.* The cost of maintenance per head of the latter class of patients had been £40 12*s.* 9¾*d.*, the rate of board chargeable for them being £42 per annum. Although in February, 1898, the managers had been compelled to raise the rate of board chargeable for pauper patients from £30 to £31, they had been disappointed in their expectation that the additional £1 of board would be sufficient to meet the cost of maintenance. During the year the cost of pauper maintenance had been £32 1*s.* 10¾*d.* per head, so that there was a deficit in that department of £740 9*s.* 3*d.* They feel, therefore, obliged to raise the rate of pauper maintenance to £32 per head for the year commencing April 1st, 1899. The increased expenditure in this department during 1898 was due to a rise in the price of flour and potatoes, the former during the greater part of the year being 3*s.* per bag dearer, while the latter had shown an increase in price of 10*s.* per ton. During the year the West House had been provided with a new boiler and boiler-house and the drainage system of that building had been reconstructed at a total cost of £1613 16*s.* 2*d.* The asylum had been visited in March by Dr. Sibbald and in November by Dr. Fraser, Commissioners in Lunacy, the reports by these gentlemen being highly satisfactory. Dr. Fraser, however, referred to the increase in the number of pauper patients and the overcrowding of West House, with the consequent difficulty in accommodating private patients at the lowest rate of board. In connexion with this point the managers reported that arrangements are being made with the District Lunacy Boards of Stirling and Lanark to provide accommodation within their districts for 60 patients from the West House. The report of the physician-superintendent, Dr. Clouston, stated that the average number of patients resident during the year was 910, of whom 447 were men and 463 women. The number of admissions—451—was the largest the managers ever had in any year except in 1894 and 1896, and had they been able to admit all the patients who applied at the lower rates of board would have been one of the highest on record. Dr. Clouston found, in reviewing the 25 years during number of patients sent to the asylum had risen gradu by 23 each quinqenniad, and last year they had rece about 200 patients more than in his first year. increase had taken place more among the rate-paid the private patients. He believed this increase was li to continue, not from any actual increase of insanity the country, but because the benefit and convenienc asylums for the insane were being more realised by community. The great aim of modern medicine was prevention of disease and its next aim was to get dis under control in its early stages. In most cases of insa one had to come to the conclusion that the disease co not have been prevented, it being usually due in the place to a predisposition to nervous instability and in second place to events in the patient's physiological his circumstances, or his surroundings over which he others had no control. Many of the cases, however, ar from over-indulgence in alcohol and immorality. Clouston went on to speak of old age in relation to insan It would evidently be an important aim of the men medicine of the future to teach how the brain might deve safely and grow old safely. He had daily evidence of thing—that after 50 years of age men and women should more careful of alcohol, of excesses, and of avoiding causes of rheumatism, gout, bronchitis, &c., because th diminishing nerve energy was less capable of coping w these enemies of health. The death-rate in the asylum dur the year had been 11·3 per cent. on the average num resident, this being 3 per cent. more than the rate in royal and district asylums of Scotland in 1897. Clouston concluded by referring among other points to favourable opinions expressed by visitors to the institut during the meeting of the British Medical Association in summer, to the fruitful work done by Dr. Ford Robertson the Scottish Asylums Laboratory, and to the appointment Dr. Middlemass to Sunderland Asylum. Dr. Clouston a said that at the conclusion of 25 years' service he app ciated more and more highly the continued kindness a indulgence of the Board of Ordinary Managers.

Edinburgh Royal Infirmary Managers.

At the meeting of the managers of the Edinburgh Roy Infirmary held on Feb. 27th sympathetic references we made to the death of Sir John Struthers and of Profess Rutherford. It was agreed that copies of a minute recordi their sorrow at the death of their friends be sent to t relatives of each. At the same meeting Dr. Allan Jamies was re-appointed for five years as physician for diseas of the skin and Mr. William Guy for one year as dent surgeon.

The Water-supply of Aberdeen.

In the summary of the vital statistics of Aberdeen for 18 just issued by Professor Matthew Hay, M.D.Edin., medic officer of health of the city, he, while admitting that the hig death-rate during the year referred to from gastric an intestinal irritation cannot be definitely ascribed to th water-supply, that the deaths from diarrhœa were under th average and that the prevalence of typhoid fever was no greater than usual if the cases due to milk infection are e cluded, goes on to say: "Nevertheless, I feel it my duty t emphatically state that as long as the aqueduct remains i such a condition that at any one point in its course sewag may at any one time find its way into the water, and as lon as the water-supply is drawn from a river open at severa points to sewage pollution and such water-supply is no filtered, then so long does the city run the risk of being sub mitted at any moment to a serious and widespread epidemi of diarrhœa, typhoid, or cholera."

Aberdeen City Hospital.

The salary of the resident physician at this hospital ha been fixed at £75 with residence for the second year's servic It commenced at £50 only.

New District Hospital near Aberdeen.

The Aberdeen District Committee of Aberdeen Count Council has agreed to erect a district hospital for infectiou diseases (14 beds) at Summerfield, near the city of Aber deen. The estimated cost is £4000 and Mr. J. D. Watson county engineer, is architect. It is the wish of the com mittee that the building should be finished and quite dr before October next.

Aberdeen Natural History and Antiquarian Society.

The following office-bearers have been appointed:—

Vice-President: Mr. William Ferguson, LL.D., of Kinmundy. Secretary: Mr. Robert M. Clark, B.Sc., assistant to Professor Trail. Treasurer: Mr. James Spence of Pow.

Lord Rectorship of Aberdeen University.

The students are already moving as to the selection of a Lord-Rector to succeed the Marquis of Huntly in November next. The names of Lord Aberdeen, Lord Rosebery, and Sir David Stewart, ex-Lord Provost of the city of Aberdeen, have been suggested as candidates and in any event a contest is expected.

Feb. 28th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Poor-law Medical Service.

A MEETING of the medical profession will be held at the Royal College of Surgeons in Ireland on March 2nd in connexion with the reforms of the Irish Poor-law medical service. The President of the Irish Medical Association will occupy the chair and in addition to others the following have promised to address the meeting: the Presidents of the Royal College of Physicians and of the Royal College of Surgeons, the Regius Professor of Medicine, Trinity College, Dublin, Sir William Stokes, Sir Thornley Stoker, Sir Charles Cameron, and others.

The University Question.

The vexed question of university education in Ireland is still much discussed and two most important letters have appeared, one from the President of Queen's College and the other from Professor Dill, M.A., late Fellow and Tutor of Corpus Christi College, Oxford, both strongly advocating on academic grounds the establishment of a university in Belfast on the lines proposed by Mr. Balfour. At a meeting of the Belfast Medical Students' Association the following resolutions were passed:—

1. That the present state of university education in Ireland is unsatisfactory.
2. That the establishment of denominational universities cannot fail to be detrimental to medical education in Ireland.
3. That the Royal University of Ireland should be maintained but that the various public colleges should be adequately endowed.

Lisburn Infirmary.

It appears from the annual report that for the year ending Nov. 30th, 1898, there were 370 patients under treatment in this infirmary. During the same period there were 607 extern cases and as regards both in- and out-patients there is an increase over previous years. There were 244 accidents attended to during the year. 40 operations were performed. The house adjoining the infirmary having been added to the hospital the nurses have been moved into it and it is expected that shortly wards will be opened in it for private patients.

Nursing in Irish Workhouse Infirmaries.

The Local Government Board are determined that they will not recognise nurses who have not received training for less than two years in a clinical hospital. The matter came on for discussion at the Londonderry Board of Guardians on Feb. 25th, when it was complained that the Local Government Board were endeavouring to confine the teaching of nurses in Ireland to Dublin and Belfast, a line of action which would be resisted by the county infirmaries and other hospitals. One of the guardians (a medical man) stated that it would be impossible for boards of guardians to get a nurse fully qualified according to the rules of the Local Government Board unless salaries of over £40 yearly were offered.

The Belfast Royal Hospital.

The quarterly meeting of the friends of this charity was held on Feb. 27th and was of interest as being the last meeting of the old hospital because the new revised charter by which the Royal Hospital is submerged in the new Royal Victoria Hospital became law on Dec. 12th, 1898, and under its conditions the annual meeting of the new corporation must be shortly held at which a new board of management must be elected. The balance due by the hospital on Oct. 31st was £3228 16s. To meet this the board decided to raise £3000 by the sale of invested capital. For the five months ending Jan. 31st £3518 9s. have been received from all sources, while the expenditure has been £4689 9s. 6d., being an outlay over receipts of £1171 0s. 6d. The debt against the hospital at the close of the last financial year was £2164 12s. 11d.; up to the end of the present quarter the debt was £1662 14s. 5d., but this will be covered by the sale of securities. A sum of £440 was realised through the sale of tickets to view the launch of the *Oceanic* and Lady Henderson (wife of the late Lord Mayor) collected from friends a sum of £150 for the charity. On Jan. 16th of this year the new Royal Victoria Hospital came into existence, when practically the old "Royal" ceased to exist and became merged in the new charter. A meeting of subscribers to the old and the new hospital will shortly be summoned to elect the new board of management and under the terms and conditions of the new charter only life governors and annual subscribers of £2 2s. and upwards will have the right to exercise the power of voting at such meeting. During the past quarter there were 599 intern (379 surgical and 220 medical) and 5851 extern cases.

Death of Dr. William C. Townsend of Cork.

I announced last week the death of Dr. William C. Townsend who for many years was the senior member of the profession in Cork. 60 years ago he commenced practice. Early in his career he was appointed one of the medical officers of the Cork Union Hospital and recognising the advantage country air would prove to the numerous tuberculous children in that institution he earnestly urged the guardians to adopt the boarding-out system. This advice was acted on and he had the satisfaction of knowing in after years that through his instrumentality many little ones, who had they remained "cabined, cribbed, confined" would have eked out a short and miserable existence, grew up vigorous and healthy members of the community. Dr. Townsend afterwards became visiting physician to the Cork South Infirmary and many of his pupils now scattered all over the globe will have a kindly recollection of his assiduous, sympathetic care of his patients and of the great zeal which he displayed in imparting to his class the information he had gained as an intelligent, observant, clinical diagnostitian. He was also visiting physician to the Cork District Lunatic Asylum and for many years had an extensive practice in the south of Ireland as a consulting physician. He had attained the ripe age of 81 years and all the public bodies in Cork expressed respect for his memory by passing votes of condolence with the members of his family.

March 1st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Rating of Private Hospitals.

A SOMEWHAT singular situation has arisen with regard to the rating of private hospitals (*cliniques*). Formerly these institutions were exempt from any tax inasmuch as they served the cause of charity as well as that of education. In 1894, however, the Chamber of Deputies raised all the taxes imposed upon the liberal professions, those of medical men being raised from one-twelfth to one-fifteenth of their rent. At the same time the tax commissioners assessed medical men who owned private hospitals not only on the rental of the hospital but also on the rental of the owners' private rooms, so that the rate payable was very largely increased. Dr. Vignes, a well-known Paris ophthalmic surgeon and the registered owner of an important private hospital, was anxious to find some way of avoiding this rate and as the rate upon *maisons de santé* is much lower than that upon private hospitals he registered his establishment as a *maison de santé*, this being quite a natural course because he had a number of beds and because he performed operations. The Council of the Prefecture, in giving judgment on appeal in this case, decided that Dr. Vignes's establishment was a real private hospital because he did not occupy the whole of the building. Dr. Vignes therefore had to pay the higher rate exacted from medical owners of private hospitals. In the meantime the Boisleux case occurred and the Prefect of Police ordered a very strict inspection of all *maisons de santé* to avoid any similar scandals in future. An inspector accordingly arrived at Dr. Vignes's establishment. Dr. Vignes, however, refused to admit him, saying with perfect truth that the Council of the Prefecture had decided that his establishment was really a private hospital and not a *maison de santé*. He also showed the inspector the receipt for the rate paid upon this assessment. The inspector was deaf to all remonstrances and made a forcible entry, when he found several female patients who had recently been operated upon in bed. The next thing was that Dr. Vignes was prosecuted for keeping a clandestine *maison de santé* and was condemned in heavy damages, while the establishment was ordered to be closed. This judgment, which shows the spite with which the tribunals pursue medical men, has astonished the members of that profession. It may be useful if I explain at somewhat greater length the difference between a *maison de santé* and a *clinique*. A *maison de santé* is a private nursing home, a purely commercial institution kept by a proprietor who is not necessarily a medical man but who receives patients for medical men who keep such patients under their own care. The patients may be medical, such as weak-minded persons, morphiamaniacs, and the like, or they may be surgical and simply go into the house for an operation. Many *maisons de santé*, especially the surgical kind, are managed by one or other of the religious communities. The *clinique*, on the other hand, belongs to one particular medical man who gives gratuitous advice. In practice, however, many *cliniques* derive their importance from possessing a few beds where the medical man receives patients for operation at low fees, the responsibility both administrative and medical being his alone. This kind of *clinique*, it will be seen, bears a close resemblance to a *maison de santé* owned by a proprietor who happens to be a medical man and from a confusion of ideas arose the incident which I have narrated.

On the Use of a Mask during Operations.

At the meeting of the Society of Surgery held on Feb. 21st, Professor Berger read a paper on the Use of a Mask by the Surgeon during Operations, especially in cases of abdominal section. According to him the particles of saliva given off by the surgeon during an operation form a by no means unimportant source of infection. He had noted the fact through bacteriological experiments that although the silk and other materials used for sutures were always perfectly aseptic before use, yet when once in contact with the wound they gave rise to stitch abscesses which though not very serious, yet healed with difficulty and were very tiresome. Since he had taken to using a mask he had noticed that his operation results had greatly improved. Of 70 operations for the radical cure of hernia performed since Oct. 1st, 1897, the date at which he first commenced the use of the mask, suppuration had occurred only in two, whereas formerly suppuration occurred in one out of every five or six cases.—Professor Tarnier said that for his part he had never used a mask and probably never should do so. He considered that sutures were infected by the hands and not through the agency of the breath. He had tried the effect of his hands upon gelatin plates both before and after operations and found that at the end of an operation they were septic. Sutures must be handled as little as possible and always taken up with forceps so as to avoid infection.—In reply Professor Berger contended that if the stitches came away it was not because they were infected but because they came from an infected wound.

An International Congress of the Medical Press in 1900.

At the last meeting of the French Medical Press Union the question of a congress of representatives of the medical press to be held at the great Congress of 1900, an idea which had been submitted at the previous meeting by Dr. Blondel, came up for discussion. The chief subject of inquiry was as to whether this congress should be a mere sub-section of the great International Congress or an independent congress. This latter view of the matter was the one finally taken in accordance with the terms of a report drawn up by Dr. Blondel, whose conclusions were unanimously adopted. In 1900, then, there will be a congress to which will be invited representatives of the medical press of the entire world. An application for incorporation among the official congresses of the exhibition was submitted to the chief committee of the exhibition—a task undertaken by Dr. Beaudouin—and the sub-committee appointed to examine applications passed this one on Feb. 24th. The organising committee will be formed by members of the French Medical Press Association and its details will be settled at the next meeting. Among the questions to be discussed at the congress is that of the advisability of forming a permanent international Medical Press Association, an idea which was first mooted at the Congress held at Rome by Dobrzychi and which was in a measure begun to be carried out at the initiative of Posner, Laborde, Beaudouin, Brown, Rubino, and others. A meeting was, as a matter of fact, proposed to be held in Brussels, but it never took place. The active work of the association, upon which was grafted an idea of centralising the work of the congress, was put off until the Moscow Congress, where, however, there was so much confusion that nothing was done. There is every reason to believe that the meeting in Paris in 1900 will prove a great success. The Association of the Italian Medical Press, through its president, Dr. Bossi, has already declared its complete adhesion to the scheme of Dr. Blondel.

The Academy of Medicine.

Lord Lister was nominated a special foreign member of the Paris Academy of Medicine on Feb. 28th.

Feb. 28th.

(From our own Correspondent.)

Diphtheria Antitoxin.

Dr. Otto Wenner, house physician to the Zürich Children's Hospital, has compiled a careful account of the cases of diphtheria under antitoxin treatment from Oct. 25th, 1894, to May 25th, 1898. The results will shortly be published in an inaugural dissertation. Of the 385 cases where bacteriological evidence could be adduced 86 were subjected to intubation and 32 to tracheotomy. 500 or 1000 units of either Behring's or Bernese antitoxin serum were injected once or repeatedly, according to the severity of the case. In 120 cases albuminuria was noticed, and this proportion of 31 per cent. contrasts very favourably with the 57 per cent. of albuminuria during the period, 1874-94, when the antitoxin treatment was not yet resorted to. The reduction of the rate of mortality during the period of antitoxin treatment is remarkable and corroborates evidence already supplied by German and English statistics.

	1874-1891	1891-1894	1894-1898
Number of cases	690	149	385
Mortality per cent.	43·8	40·3	9·8
Cases operated on	404	79	118
Mortality per cent.	63·4	65·8	19·4
Cases not operated on	286	70	267
Mortality per cent.	16·1	11·4	5·6

Diphtheria and Heart Disease.

At the last meeting of the Medical Society of Zürich Professor Ribbert reported on four cases of sudden death from heart collapse in diphtheria. Evidence of considerable degeneration of the muscular tissue was forthcoming in each case, there being hardly any inflammatory processes. The best histological stain was a combination of hæmatoxylin with picramic acid and acid fuchsin. No bacteria could be found in the tissues and the degeneration in such cases is due to the effect of the toxins produced.

Clinical Society of Zürich.

The meetings of this society, which are held every two months either in Zürich or Berne, continue to be well attended and prove very instructive to the general practitioner, as subjects of general interest are always chosen. On Feb. 6th Professor Eichhorst lectured on the Diagnosis of Diseases of the Digestive Apparatus. Professor Muller demonstrated some interesting cases of Herpes Tonsurans Capillitii, an affection as rare in Switzerland as it is common in England; there were eight cases in one family all infected from one English boy. He also demonstrated a very obstinate case of Sycosis Parasitaria in which dressings of corrosive sublimate proved very efficacious.

Death of Professor Socin.

The Bâle Medical Faculty deplores the loss of Professor Socin who died on Jan. 21st at the age of 62 years after having been professor of clinical surgery since 1864. He studied at the universities of Bâle and Wurzburg where he graduated in 1857. He took an active part as surgeon in the Franco-Prussian War and his experiences, published in 1872, were of great interest. His chief work was a book on prostatic disease which came out in 1875 as part of Pitha and Billroth's

"Encyclopæpia of Surgical Pathology." He was a very genial man, full of wit and humour, devoted not less to medical science than to art and music, and his death leaves a void in local society.

The Orthopædic Institute of Zürich.

Dr. W. Schulthess has been demonstrating the following cases to the Medical Society of Zürich. 1. A child, aged six years, with Partial Paralysis of the Left Leg from the Knee downwards, combined with Partial Muscular Hypertrophy. It is of interest that the mother of the child had a severe fall during pregnancy. A photograph of the patient at the age of one year distinctly showed a difference, now more pronounced, in the two feet, so that the paralytic affection must have occurred either during uterine life or in the earliest period of infancy. There was partial paralysis of the anterior and posterior tibial muscles, hypertrophy of all the posterior muscles of the left leg from the knee downwards, otherwise muscular atrophy (? retraction), shortening of the left leg, and secondary pes equino-varus. Slight differences in the muscles of the left arm pointed to a cerebral origin of the paralysis. 2. A boy, aged 16 years, who from early youth had showed signs of severe scoliosis, which, however, did not hinder him from going to school and running about like other children. At the age of 15 years increasing weakness in both legs supervened without any previous illness or any symptoms of spondylitis; this was followed by spastic paralysis, which persists to this day. Dr. Schulthess considered it to be a case of a rare condition—namely, compression myelitis due to the scoliosis.

Zürich, Feb. 23rd.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The League against Tuberculosis.

ITALY long stood alone among continental countries in maintaining that pulmonary phthisis was communicable, and English-speaking physicians in Rome and Florence used to complain of the difficulty, sometimes insuperable, of getting phthisical patients admitted into hotels or pensions except at a price which would leave the proprietor free to shut his house against all other arrivals. Right in her surmise, for it was nothing more, Italy has now to follow the lead of those countries which have come round to her way of thinking, and at this moment is actively copying their provisions for limiting the spread of the disease and for promoting its cure in cases where it has been established. At Padua on Feb. 22nd a very important meeting was held at which public hygienists, the occupants of academic chairs in medicine (theoretical and clinical), and general practitioners combined to found "una lega nazionale contro tubercolosi." The rector of the University, Dr. Achille de Giovanni, who is also professor of clinical medicine, presided, and in the course of a powerful and impressive speech he described the urgent necessity for such a new departure and he also set forth the lines on which it will proceed. The league will be composed of regional committees and these will elect the national committee which will have its headquarters in Rome. Next week a not less important meeting will be held in Turin and Dr. Pio Foà, the distinguished professor of general pathology and supplemental lecturer on bacteriology in the university, will be the spokesman of the occasion. His special theme will be "Sui Sanatori popolari per la cura della Tubercolosi," and his discourse will be at once a scientific exposition and a medical propaganda. An anticipation of its tenour with which I have been favoured indicates his line to be the following. Popular sanatoria are in these days the solution of a tripartite problem—(1) medical, (2) hygienic, and (3) social. Medicine claims first consideration, because in the sanatoria for tuberculosis her "cures" attain the high proportion of 30 per cent., while her "improvements" are at least 45 per cent. Hygiene comes next, since in the sanatoria, and in these alone, the patient succeeds in mastering the methods by which he preserves those around him from the contagion of the disease. Sociology takes the third place—phthisis (or pulmonary tuberculosis) being but the most pronounced form assumed by "miseria fisiologica" (physiological impoverishment) and in the last resort by the economic "miseria" of an individual or a race. The foundation of popular sanatoria for the treatment of phthisis is therefore the practical outcome of that principle of mutual aid according to which the more favoured assist the less favoured classes—assist them, moreover, not by the fitful relief of a "charity," often capricious and always incomplete, but in conformity with the methods of an intervention at once continuous, direct, and well-systematised. All civilised countries have, to a greater or smaller extent, equipped themselves with such sanatoria. Germany, France, Switzerland, Austria, and others are already provided with them. Italy alone, as I have said, has still to follow, and not a day too soon. According to the latest statistics tuberculosis kills 70,000 of her inhabitants every year and reduces to the invalid state well-nigh 1,000,000 within the same period. Hitherto she has been content to look on and to report the success of neighbouring nationalities, as of Switzerland at Bâle and of France at Lyons; but now the initiative taken by Padua and Turin will be imitated in some of her other great centres and the projects already formulated by such municipalities as those of Brescia and Milan will have their counterparts in cities further south. Rich in climatic resorts of every kind, Italy has a magnificent opportunity of utilising these in the foundation of "sanatori popolari" and of showing to Europe what she is capable of in her hygienic as well as in her political "risorgimento." On a minor scale, indeed, she has demonstrated what she can do for the prevention and treatment of such local epidemics as pellagra—the "pellagrosai" in Lombardy having already more than justified their institution. Here again her activity is laudably on the increase, and at Padua, on April 8th, she will hold a congress "contro la pellagra" which is to last three days and at which not only the Venetian but the Lombard communes will be largely represented.

Professor G. B. Grassi on Recent Studies in Malaria.

In a lecture delivered before a mixed but chiefly professional audience on Feb. 26th at Milan Professor Grassi gave his most recent views on the accessions made to our knowledge of "malaria." The cause, essential and primary, of the fever is, he said, "a sporozoon, an organism infinitely small, developing itself through a special evolutionary cycle in a particular species of mosquitoes affecting malarious localities, which sporozoon is inoculated in man by the puncture of the said species of mosquitoes." The lecture re-traversed the ground already traced in this correspondence and need be referred to no further than as confirming the account of the Italian contributions to the discovery of the special mosquito (the *anopheles claviger*) already given to your readers. Of more interest was Professor Grassi's conclusion as to the "mode of combating malaria." This consists in "making war on the mosquitoes, destroying them, and so preventing their reproduction." The marsh waters, he said, in malarious districts from being stagnant should be made to flow. Drainage on a large scale is not needed for this object. It would suffice, in the months during which the mosquitoes are prolific, to carry out "proscingamenti temporanei" (temporary dryings up or soil desiccation). This, he assured his audience, would "save entire regions from a terrible scourge."

Feb. 25th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

The Imperial Medical Society.

THE Imperial Medical Society held an extraordinary meeting on Feb. 15th to receive the report for the past year and to elect the President and officers for the current year. Dr. Stekoulis presided and opened the meeting with a brief address, in which he stated its objects. He announced that the endeavours of the society to render obligatory the notification of infectious diseases were likely to prove successful. The secretary then read the report of the past twelvemonth, gave a summary of the more important discussions, and drew attention to the number of original papers, many of which treated of surgery, ophthalmology, epidemiology, and rare cases. He spoke at great length of phakotherapy and the confirmation which modern experience was giving to M. Apéry's theories. After referring in terms of regret to the death of two valued members, Dr. Plessa and Dr. Nuridjian, he enumerated the honours and distinctions which the Sultan had bestowed upon members of the society and concluded with declarations of loyalty which were received with cheers for His Imperial Majesty. The elections then took place, Dr. Stekoulis being re-elected President. In the evening 23 members dined together to celebrate the forty-fourth anniversary of the society.

Mortality in Constantinople.

The mortality returns for January show a total of 1445 deaths, of which 887 were of Mussulmans (444 males and 443 females), 474 of Christians (272 males and 202 females), and 84 of Israelites (40 males and 44 females). Unusually fine as the winter has been this year there is, nevertheless, much illness about, more especially pneumonia and other affections of the respiratory organs brought on by imprudent exposure and carelessness. During last week 53 deaths—nearly 18 per cent. of the total—were due to diseases of this character.

Small-pox.

In view of the spread of small-pox in different parts of the metropolis, 14 deaths from this cause having occurred last week, an Imperial Iradé has been issued which orders especial precautions and efficient measures to be taken against the spread of the disease. Public vaccinators have been appointed whose duty will be to visit every quarter of the city and compulsorily vaccinate the pupils of different schools as well as grown-up persons. Some of the thickly populated quarters are in an excessively unhygienic condition and the authorities are trying to cleanse the streets. I am sorry to record that the British Postmaster, Mr. Frederick Stewart Cobb, died on Feb. 16th at the French Hospital, at the age of 56 years. Mr. Cobb was taken unwell on Feb. 7th and small-pox declared itself on Feb. 10th, when he was at once conveyed to the French Hospital. Being unfortunately in a very enfeebled state of health he was unable to offer much resistance to the disease. His death is a calamity for the British colony here.

Feb. 21st.

Medical News.

ROYAL COLLEGE OF SURGEONS IN IRELAND: FELLOWSHIP EXAMINATION.—The following candidates having passed the necessary examination have been admitted Fellows of the College:—

Mr. J Knox Denham, L.R C S Irel , Mr. E J. Moore, L.R C.S Irel , and Mr. T. G. Stevens, L R C.S Irel.

The following candidates have passed the primary part of the examination for the Fellowship of the College:—

Mr R. J Coulter, B Ch. R.U.I , Mr. J. P. Frengley, B Ch R U I , Mr. R D. Joyce, M R.C S Eng , Mr. C. R. Boyce, Mr. E Glenny, Mr. P. J. Hanafin, Mrs. H. L. Hennessy, Mr. J. M. S. Levis, and Mr. J. F. Peart.

APOTHECARIES' HALL OF IRELAND.—The following candidates have passed the recent examinations for the Licence in Medicine, Surgery, and Midwifery:—

Physiology—S. Adye Curran and L. J Farrell
Anatomy—S Adye Curran and A. J. Barnes.
Materia Medica—A. J. Barnes.
Pathology—W. P. Harding
Surgery—W. W Feris
Midwifery—W W. Feris
Ophthalmic Surgery—W. W Feris.
Completed third professional examination—W. P. Harding.

The following have received the diploma of the Hall:—F. G Adye Curran, W. P Delahunt, J. D Power, M P. O'Brien, and J. J. Ahern

VACCINATION AT GLOUCESTER.—At the meeting of the Gloucester Board of Guardians held on Feb. 21st it was decided by 28 to 15 votes to rescind a former resolution with regard to vaccination and the appointment of public vaccinators and to proceed to the appointment of a vaccination officer and public vaccinator for No. 1 district and to otherwise carry out the requirements of the General Order of the Local Government Board in regard to vaccination.

CREDITON BOARD OF GUARDIANS AND MIDWIFERY FEES.—At the meeting of the Crediton Board of Guardians held on Feb. 18th the case of Mr. Haycroft, M.R.C.S. Eng., and the midwifery fee which was reported in THE LANCET of Feb. 18th was discussed. A member moved a resolution that the case be carried to a higher court. This was seconded, but an amendment moved by Sir John Shelley that the matter be dropped was carried by a large majority.

Up to the present £1287 have been received by the council of the Hospital Sunday Fund at Bristol.

MEMORIAL TO THE LATE DR. MARSHALL.—The Dean of Bristol has received £400 towards erecting a memorial to the late Dr. Henry Marshall of Clifton. With this sum a tablet to the memory of the deceased has been placed in the Bristol Cathedral and the remainder has been invested. The dividends of this are to be devoted to an annual prize to be given to the best dresser of four years' standing at the Bristol General Hospital, of which institution the late Dr. Marshall was formerly consulting surgeon.

CHRONIC ARSENICAL POISONING.—At the meeting of the Tavistock Board of Guardians held on Feb. 24th Mr. C. C. Brodrick, medical officer of health of the Tavistock rural district, and Mr. A. Bowhay, medical officer of health of the Calstock rural district, presented a report upon the pauperism prevailing among families of men formerly employed in arsenic works at Calstock. They attributed this to the early age at which arsenic workers were disabled through inhaling arsenical fumes and made suggestions for their better protection while at work. The guardians decided to send copies of the report to the Local Government Board and managers of arsenic works in the district.

LITERARY INTELLIGENCE.—Sir William MacCormac will publish immediately, through Messrs. Smith, Elder, and Co., the "Hunterian Oration" which he delivered on Feb. 14th at the Royal College of Surgeons of England in the presence of H.R.H. the Prince of Wales.—G. P. Putnam's Sons announce the publication of a new quarterly journal devoted to the interests of anthropology. This periodical which has been established under the auspices of Section H of the American Association for the Advancement of Science, to which section is given over the study of anthropology will be issued under the title of "The American Anthropologist (New Series)" and the secretary and managing editor is Mr. F. W. Hodge, 1333, "F"-street, N.W., Washington, D.C.

ACTION AGAINST A DENTIST.—The case of Wilkins *v.* Hayman and Kendall was tried at the Bristol Assizes before Mr. Justice Mathew on Feb. 21st. The plaintiff claimed damages against Mr. H. Hayman, L.D.S.R C.S. Eng., and Mr. H. Kendall, L.R.C.P. Lond., M.R.C.S. Eng., for negligence. Evidence showed that plaintiff consulted Mr. Hayman in reference to his teeth and he was advised to have some removed under ether. This anæsthetic was administered by Mr. Kendall and the plaintiff alleged that Mr. Hayman removed more teeth than he (Wilkins) agreed to and that Mr. Kendall gave too much ether and left him before he had recovered from it. Witnesses stated that the plaintiff had suffered from a severe attack of malaria contracted abroad and that after the operation there was a considerable amount of hæmorrhage and that a portion of a tooth was left in the mouth. The defence was that the dentist was authorised to remove what teeth were necessary, that the plaintiff was sufficiently recovered after the operation to speak to the defendants who had left their addresses with the patient's friends in case their services should be required. The plaintiff's friends, however, sent for his regular medical attendant. Eventually after two minutes' deliberation the jury returned a verdict for the defendants with cotss.

MANCHESTER HOSPITAL FOR CONSUMPTION.—The annual meeting of this institution was held on Feb. 21st when the report of the board of management was received and passed unanimously. It stated that the total cost of the in-patient department was £1894 16*s.*, as against £2027 2*s.* 3*d.* in 1897. The increased cost was due to the fact that from Jan. 1st until July 31st the women's wards were entirely closed owing to the alterations, while no reduction could be made in the permanent staff. The open-air treatment now so generally recommended was about to be tried at the hospital at Bowdon through the liberality of the chairman. This would be one of the first hospitals in this country at which this system would be tried. The report of the medical board regarding the out-patient department stated that although the number of the total attendances of patients did not reach the record of 1894, yet the number of new patients treated was considerably above the average of preceding years. The number of new patients was 10,914.

Kempe, Gilbert, M.D., B.S. Durh., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer of Health for the Salisbury Rural District.

Kilvert, J. E., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

Lambert, J. R., M.B. Vict., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health by the Farsley District Council.

Langston, J. J., L.R.C.P. Irel., has been appointed Medical Officer for the No. 6 Sanitary District of the Lambeth Union.

Laverick, J. T. B., M.B., M.S., D.P.H. Glasg., has been appointed Medical Officer for the Lythe Sanitary District of the Whitby Union.

Lucas, S. A., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

Mayer, D., M.B., C.M. Aberd., has been appointed Parochial Medical Officer by the Dyce Parish Council.

Miller, W. R., B.A., M.D., B.Ch., has been appointed Admiralty Surgeon and Agent for Penzance and District, vice Humphry Davey, deceased.

Nott, A. H., Captain, M.B., M.R.C.S., I.M.S., has been appointed Clinical Assistant to the Chelsea Hospital for Women, Fulham-road, London.

Phillips, H. J., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

Roberts, K., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Ampthill Rural District Council.

Ross, E. H., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Medical Officer to the Infirmary, Parish of St. Mary, Lambeth.

Ross, E. H., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant House Physician to St. Thomas's Hospital.

Sargent, P. W. G., M.A., M.B., B.C. Camb., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

Scaping, H. M., B.A. Camb., L.R.C.P., M.R.C.S., has been re-appointed a Clinical Assistant in the Special Department for Diseases of the Skin at St. Thomas's Hospital.

Singer, H. D., M.B. Lond., L.R.C.P., M.R.C.S., has been re-appointed House Physician to St. Thomas's Hospital.

Sproulle, A. E., L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer of Health by the Withernsea Urban District Council.

Stevens, A. E., M.B. Durh., L.R.C.P., M.R.C.S., has been appointed House Physician to St. Thomas's Hospital.

Stuart-Low, William, F.R.C.S. Eng., has been appointed Assistant Surgeon to the Hospital of St. Francis, New Kent-road, London.

Taylor, E. C., M.D. Lond., F.R.C.S., L.R.C.P., M.R.C.S., has been appointed Medical Officer for the Workhouse, Parish of St. John, Hampstead.

Taylor, H., L.R.C.P. Edin., M.R.C.S., has been re-appointed Medical Officer by the Smallburgh Rural District Council.

Terry, C., M.R.C.S., has been re-appointed Medical Officer to the Nos. 1 and 3 Sanitary Districts, Newport Pagnell Union.

Thwaites, G. B., L.R.C.P., M.R.C.S., has been re-appointed House Physician to St. Thomas's Hospital.

Thorp, H. C., M.A., M.B., B.C. Camb., has been appointed Assistant House Physician to St. Thomas's Hospital.

Ubsdell, Henry, M.R.C.P. Lond., has been re-appointed District Medical Officer for Staverton and Rattery by the Totnes Board of Guardians.

Weldon, W. F. R., M.A., F.R.S., has been appointed Linacre Professor of Comparative Anatomy at Oxford, vice Professor R. Lankester.

Whittome, H., M.D., C.M. Edin., has been appointed Assistant Physician to the Hospital of St. Francis, New Kent-road, London.

Vacancies.

For further Information regarding each vacancy reference should be made to the advertisement (see Index).

Bristol City Hospitals.—Resident Medical Officer at the Ham Green Fever Hospital, Bristol, for one year. Salary £100 per annum, with board, lodging, and washing.

Charing-Cross Hospital, London.—Assistant Anæsthetist.

Coventry and Warwickshire Hospital, Coventry.—Assistant House Surgeon for six months. Salary at the rate of £50 per annum, with rooms in the hospital, board, washing, and attendance.

Cumberland and Westmoreland Asylum, Garlands, Carlisle.—Junior Assistant Medical Officer, unmarried. Salary £80 a year, with board and residence.

Cumberland Infirmary, Carlisle.—Assistant House Surgeon for one year. Salary £40 per annum, with board, lodging, and washing.

Chelsea Hospital for Women, Fulham-road, S.W.—Registrar for three years, subject to annual re-appointment. Honorarium 20 guineas per annum.

County Asylum, Whittingham, Lancashire.—Junior Assistant Medical Officer, unmarried. Salary commencing at £100 per annum, increasing to £250 according to promotion, with furnished apartments, board, attendance, and washing.

Dental Hospital of London, Leicester-square.—Assistant Anæsthetist.

Dental Hospital of London Medical School, Leicester-square.—Demonstrator in Dental Histology. Honorarium of £25 a year.

Great Northern Central Hospital, Holloway-road, London.—Junior House Surgeon for six months. Salary at the rate of £30 per annum, with board, lodging, and washing in the hospital.

King's College, London.—Assistant Aural Surgeon. Also Physician or Surgeon-in-Charge of the Skin Department.

Leicester Infirmary.—Assistant House Surgeon for twelve months. Honorarium £42, and board, residence at the Infirmary, and washing provided.

Liverpool Northern Hospital.—Assistant House Surgeon. Salary £70 per annum, with residence and maintenance in the house.

London Temperance Hospital, Hampstead-road, N.W.—Assistant Medical Officer for six months. Residence in the hospital, board, and washing provided, and an honorarium of 5 guineas given conditionally.

London Hospital, Whitechapel, E.—Surgical Registrar. Salary £100 per annum.

Metropolitan Hospital, Kingsland-road, N.E.—House Physician, House Surgeon, Assistant House Physician, and Assistant House Surgeon, for six months. Salaries for House Physician and House Surgeon at the rate of £40 a year, and for the Assistant House Physician and Assistant House Surgeon at the rate of £20 a year.

Miller Hospital and Royal Kent Dispensary, Greenwich-road, S.E.—Junior Resident Medical Officer for six months. Salary £40 per annum, with board, attendance, and washing.

Roxburgh District Asylum, Melrose.—Assistant Medical Officer. Salary £100 per annum, with furnished quarters, board, washing, and attendance.

Royal Berks Hospital, Reading.—Assistant House Surgeon for six months. Salary £30, with board, lodging, and washing.

Royal College of Physicians of London and Royal College of Surgeons of England Conjoint Laboratories.—Director of the Conjoint Laboratories.

Royal National Hospital for Consumption, Ventnor.—Clinical Assistant (qualified or unqualified) for three or six months. Residence, board, and washing provided. Applications to Mr. G. H. Parry, M.B., Resident Medical Officer.

Staffordshire General Infirmary, Stafford.—Assistant House Surgeon. Salary £30 per annum, with board, lodging, and washing.

St. George, Hanover-square, Provident Dispensary, Little Grosvenor-street, London, W.—Resident Medical Officer. Salary £100, with allowance about £80, and residence at the dispensary.

South Devon and East Cornwall Hospital, Plymouth.—Assistant House Surgeon for six months. Salary at the rate of £50 per annum, with board and residence.

Stockport Infirmary.—Assistant House and Visiting Surgeon. Salary £70 per annum, with board, washing, and residence.

University of Glasgow.—Professor for Chair of Pathology. Normal salary £1100.

University of London, Burlington-gardens, W.—Examiners.

Victoria Hospital for Consumption, Edinburgh.—Resident Physician for six months. Residence and board provided, in addition to a nominal honorarium at the rate of £20 per annum. Also Non-resident Medical Officer for Out-patients for six months. Salary at the rate of £60 per annum.

West London Hospital, Hammersmith-road, W.—House Physician and House Surgeon for six months.

Births, Marriages, and Deaths.

BIRTHS.

Atkinson.—On Feb. 25th, at Elmhurst, Hampton-hill, Middlesex, the wife of G. L. Atkinson, M.R.C.S., L.R.C.P., of a son.

Cole.—On Feb. 23rd, at Sneinton-road, Nottingham, the wife of George Cole, M.R.C.S., L.R.C.P., of a daughter.

Griffiths.—On Feb. 23rd, at Andover-terrace, Cheltenham, the wife of J. Hugh St. D. Griffiths, L.R.C.P., L.R.C.S. Edin., late Surgeon R.N. of a son.

Haslewood.—On Feb. 25th, at 1, Aspinall-street, Prescot, Lancashire, the wife of C. Haslewood, M.B., C.M. Aberd., of a son.

Matthews.—On Feb. 26th, at Hickman-road, Penarth, Glamorganshire, the wife of Charles E. Matthews, M.D., of a son.

Wyborn.—On Feb. 24th, at Camden-road, N., the wife of W. E. Wyborn, M.R.C.S., L.R.C.P. Lond., of a daughter.

MARRIAGES.

Bell—Penruddocke.—On Feb. 28th, at St. John's Cathedral, Hong-Kong, by the Rev. F. R. Cobbold, M.A., Dr. John Bell, *Government Medical Department*, to Annie *Elizabeth*, eldest daughter of J. H. Penruddocke, Esq., late H.E.I.C.S., of Winkton, Hants (by telegram).

Morton—Macpherson.—On Feb. 28th, at Christ Church, Bayswater, by the Rev. C. Ridgeway, William Britain Morton, M.D. Lond., of Brislington, eldest son of William Morton, Esq., of Gayles, Yorks, to Louisa Elizabeth, daughter of the late Hon. John A. Macpherson, of Melbourne.

DEATHS.

Arkle.—On Feb. 22nd, at 66, Wimpole-street, W., from pneumonia, Charles Joseph Arkle, M.D., F.R.C.P., fifth son of the late Benjamin Arkle of Liverpool, aged 37.

Bass.—On Feb. 24th, at Upper Wimpole-street, W., Frederick Bass, M.D., F.R.C.S., aged 47.

Forbes.—On Feb. 23rd, Arthur Daniell Forbes, M.B., fourth son of the late Dr. Chas. Forbes, R.N., at Horsmonden, Kent, aged 33 years.

McBride.—At Arundell-villas, Weston-super-Mare, suddenly, Alexander McBride, M.D., Fleet Surgeon, R.N., aged 67.

Struthers.—On Feb. 24th, at George-square, Edinburgh, Sir John Struthers, M.D., LL.D., Emeritus Professor of Anatomy, University of Aberdeen, aged 76.

Willshire.—On Feb. 24th, at Great Marlborough-street, W., Wm. Hughes Willshire, M.D., in his 83rd year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS

METROPOLITAN HOSPITALS

MONDAY (6th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (9.30 A.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.), London Throat (2 P.M.).

TUESDAY (7th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.).

WEDNESDAY (8th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.).

THURSDAY (9th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.).

FRIDAY (10th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.).

SATURDAY (11th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES

MONDAY (6th).—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. S. West: Some of the Clinical Aspects of Granular Kidney (Lettsomian Lecture). Lecture III.—Syllabus: The symptoms are late. Diagnosis often difficult. Cardiac symptoms. Hæmorrhage. Chronic Renal Toxæmia. General Cachexia. Gastro-Intestinal Symptoms. Nervous Symptoms. Respiratory Symptoms. Renal Asthma. Skin Eruptions. Acute Renal Toxæmia=Acute Uræmia. Treatment. Conclusion.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-square).—7 P.M. Council Meeting. 8 P.M. Papers:—Mr. C. S. Tomes: A Remarkable Diseased Tooth.—Dr. F. T. Paul: A Contribution to the Histological Study of Dentine. Casual Communication: Mr. L. Bartlett: The Relief of Trouble from an Impacted Lower Wisdom Tooth.

TUESDAY (7th).—PATHOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Adjourned Discussion on Pseudo-tuberculosis. The following speakers are expected to take part:—Dr. Payne (President), Prof. J. MacFadyean, Mr. Foulerton, Dr. Wethered, Mr. W. G. Pakes, and Dr. W. S. Lazarus Barlow. Lantern slides, microscopic slides and specimens illustrating Pseudo-tuberculosis will be shown. Other Card Specimens will also be shown.

CHELSEA CLINICAL SOCIETY (Jenner Institute of Preventive Medicine, Chelsea-gardens, Grosvenor-road, S.W.).—8.30 P.M. Extra Meeting. Dr. A. Macfadyen: Enteric Fever and Diphtheria in their Bacteriological Aspects.

WEDNESDAY (8th).—DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—5.15 P.M. Demonstration of Clinical Cases.

MEDICAL SOCIETY OF LONDON.—7 for 7.30 P.M. 126th Anniversary Dinner at the Whitehall Rooms, Hôtel Métropole.

HUNTERIAN SOCIETY.—8.30 P.M. Pathological Evening. Specimens will be shown by Sir H. Beevor, Dr. Goodall, Mr. Oliver, Mr. Targett, and other Fellows.

THURSDAY (9th).—BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Specimens will be shown by Mr. C. Ryall and Dr. W. Ramsay. Papers: Dr. G. Bantock: The Modern Doctrine of Bacteriology with special reference to Gynæcology.—Dr. J. Oliver: Adenoma Universale of the Endometrium.

SOCIETY OF ARTS (Imperial Institute, South Kensington).—4.30 P.M. Mr. H. A. Acworth: Leprosy in India.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8 P.M. Card Specimens. 8.30 P.M. Papers:—Mr. C. D. Marshall: Epithelial Implantation Cysts of the Iris.—Mr. W. Dodd: Green Vision in a Case of Tabes Dorsalis.—Mr. A. Lawson and Mr. Sutherland: Further Note on a Case of Albuminuric Retinitis in a Child.—Mr. R. Donaldson: Strabismus Fixus.

FRIDAY (10th).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Papers: Mr. B. Robinson: Hydatid Cysts of the Upper Lobe of the Right Lung and Liver successfully removed.—Mr. A. E. Barker and Dr. N. Nabarro: A Case of Pancreatic Cyst treated by Incision and Drainage.—Mr. Battle: Removal of a large Fungating Tumour of the Skull with subsequent Grafting of the Dura Mater.—Mr. A. Fenn: A Case of Erasion of the Ankle-joint, illustrating a new Operative Procedure.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (6th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. F. G. Parsons: Joints of Mammals contrasted with those of Man.

ROYAL INSTITUTION OF GREAT BRITAIN.—5 P.M. General Monthly Meeting.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. L. A. Bidwell: The Examination of the Abdominal Viscera.

TUESDAY (7th).—ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. G. R. Murray: The Pathology of the Thyroid Gland (Goulstonian Lecture).

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck-street, W.).—4 P.M. Dr. T. D. Savill: Electricity in the Treatment and Diagnosis of Diseases of the Nervous System.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Mr. Ballance: Surgery of the Nervous System.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. E. Ray Lankester: The Morphology of the Mollusca.

WEDNESDAY (8th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. F. G. Parsons: Joints of Mammals contrasted with those of Man.

EVELINA HOSPITAL (Southwark Bridge-road, S.E.).—4.30 P.M. Dr. P. Willcocks: Clinical Demonstration on Medical Cases from the Wards. (Post-Graduate Course.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Acland: Bronchiectasis.

THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—8 P.M. Discussion on the Establishment of Public Abattoirs in the Metropolis in relation to the Prevention of Tuberculosis. Opened by Dr. W. A. Bond.

ROYAL LONDON OPHTHALMIC HOSPITAL (Moorfields).—1 P.M. Mr. Nettleship: Retro-bulbar Neuritis.

THURSDAY (9th).—ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. G. R. Murray: The Pathology of the Thyroid Gland (Goulstonian Lecture).

CHARING-CROSS HOSPITAL.—4 P.M. Mr. Gibbs: Demonstration of Surgical Cases. (Post-Graduate Class.)

LONDON TEMPERANCE HOSPITAL.—2 P.M. Dr. S. Fenwick: Clinical and Pathological Demonstration to Senior Students.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. L. A. Bidwell: The Examination of the Abdominal Viscera.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Barlow: Demonstration of Selected Cases.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square, W.C.).—4.30 P.M. Dr. A. Eddowes: Cases of Keloid and other Affections of Scars.

FRIDAY (10th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. F. G. Parsons: Joints of Mammals contrasted with those of Man.

ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Prof. H. L. Callendar: Measuring Extreme Temperatures.

SATURDAY (11th).—ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Right Hon. Lord Rayleigh: The Mechanical Properties of Bodies.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

THE HOUSE SURGEON'S FEES UNDER THE WORKMEN'S COMPENSATION ACT.

THIS is a subject to which we have already referred several times and to which we shall certainly have to recur. It is one where the rights and wrongs of a difficult question can only be arrived at by the laying together of heads. The decision of any one hospital to allow certain fees to be paid to their residents cannot be made a rule for all hospitals, nor can the willingness of one insurance office to pay certain fees be quoted as a precedent to another office. But as the customs which generally prevail become generally known we feel certain that a good understanding will be established between the house surgeon (we say house surgeon as he is the officer usually concerned, but our remarks apply equally to the house physician or the resident medical officer) and such medical men as have a right to seek particulars concerning a case where compensation is in question.

In the first place, then, if a house surgeon is asked for an opinion on a case he is entitled to a fee. Whether that fee should go into his pocket or into the funds of the institution which employs him is another question and one which we will not omit to notice. But the first thing to insist upon is that the house surgeon's duties are to look after the patients under his care, to treat emergencies as they arise, and to fulfil his superior officers' directions. He is not a person to whom all and sundry may run for certificates to absent themselves from work or from school, for recommendations to employers, or for letters to charities or convalescent homes. As a rule his time is completely occupied by his discharging his just responsibilities and he is not to be treated as a jack-in-office, or as uncivil, or as ignorant because he cannot accede at once to all the requests that may be made to him. Now, whether the victim of an accident receives money from his employer or not in compensation *has nothing to do with the house surgeon* unless the governing body of the hospital have given him to understand that the matter is one in which he is to take an interest. If the governing body instruct him that he is to be ready to give all information to such medical men as have a right to ask for it upon cases of accident where compensation is in question he will, of course, do the bidding of his employers; but as the governing body in such a case would almost certainly fix a scale of fees for him he has no discretion in pecuniary matters. He gives the necessary information in return for the fixed fee and if the fixed fee is not forthcoming he refuses the information and refers his interlocutor to the governing body. But where the governing body of the hospital have not taken official cognizance of the matter at all, so that the house surgeon is free to act on his own initiative, he should try to exercise towards his medical colleagues all proper courtesy. He should not ask an exorbitant fee, but one as commensurate as he can make it with the particular demand on his time and the amount of compensation at stake. He should remember that in the higher walks of life men are constantly asked to do a little over and above that which it is their strict duty to do, and expected cheerfully to comply. It is well for the parlour-maid to object to do this or that because it is the house-maid's work, but medical men never have approached, and we hope never will approach, their obligations in this spirit. As general hints we would suggest, then—firstly, that the house surgeon should give what help he can; secondly, that he should always be paid a fee; and, thirdly, that the fee should range from 10s. 6*d*., according to the demands made upon his time. A scale has, we believe, been adopted by Guy's Hospital in which 10*s*. 6*d*. is asked for a short consultation, £1 1*s*. for a longer one, and £2 2*s*. for a consultation and written report. This seems to us to be fair.

And to whom should this fee belong? We think to the house surgeon although we know that the governing bodies could make out a sound claim. The house surgeon is their officer and the fee is earned in time owned by them. But he is also a very hard-worked officer; the amount that he will gain by such fees is trifling and the work done for them is outside his strict sphere. We believe no hospital asks its resident officers to refund fees earned as medical witnesses though here the hospital suffers a distinct loss of its officers' time. We think the house surgeon should be allowed to retain the fees earned under the working of the Workmen's Compensation Act.

"EUCALYPTUS GLOBULUS."

To the Editors of THE LANCET.

SIRS,—In a letter from a Tasmanian correspondent on the above subject in THE LANCET of Nov. 12th, 1898, you summarise some of his remarks in a footnote as follows: "Dr. Benjafield gives a warning against those purveyors of drugs that sell oil distilled from other varieties of eucalyptus than the globulus. Such oils, he says, are comparatively useless." Such a statement is utterly without foundation in fact, as anyone who knows anything of the subject will admit, and it is somewhat surprising to read of a colonial medical practitioner giving expression to such a misleading statement. It is almost needless to point out that while the oil from the eucalyptus globulus is generally a very good article there are other oils on the market which perhaps more closely answer the tests of the new Pharmacopœia as well as contain a larger percentage of eucalyptol, the recognised active principle of these oils. Further, it has been quite recently demonstrated by a series of exhaustive analyses published in one of the leading drug trade journals that a large percentage of eucalyptus globulus oils on the English *market will not answer* all the tests of the new British Pharmacopœia, and perhaps when we consider the widely different sources from which this oil is obtained—Algiers, California, and Tasmania—and the consequent variations of season, soil, and climate, it is little wonder there should be variation in the samples examined, so that the fact of an oil being the product of eucalyptus globulus or any other variety has of itself been very *wisely discarded in the new Pharmacopœia* as any guarantee to its medicinal activity. One thing is certain, that while the Pharmacopœia Committee have ignored the botanical or geographical sources as a matter of little importance the stringent tests laid down by them will as certainly exclude inferior globulus oils as well as those of other species and yet will include others which do not *claim to be globulus* oils, but which have an already world-wide reputation for purity, excellence, and uniformity of character, not only with the British medical profession but with the leading medical practitioners throughout both hemispheres.

I am, Sirs, yours faithfully,
W. J. BROWNSCOMBE, Pharmaceutical Chemist.
Elsternwick, Victoria, Jan. 3rd, 1899.

ROENTGEN RAY OUTFITS.

Mr. G. STEGMANN, electrical engineer, of 45, St. John's-hill, Clapham-junction, S.W., has submitted to us for inspection his new list of Roentgen ray apparatus. It records several important improvements in accessories—as, for example, in the Crookes's tube and in the mercury interrupter. It is also stated that he has always a complete 12-inch installation at work in his laboratory.

"AN IMPROPER ADVERTISEMENT."

To the Editors of THE LANCET.

SIRS,—I notice in THE LANCET of Feb. 25th a letter under the above heading calling attention to an advertisement in *Lloyd's Weekly Newspaper* of a "Toothache cure" ("Ibis"), with the name of a Licentiate of Dental Surgery displayed in full. You remark that "the advertisement *is one to which the attention of the Royal College of Surgeons of England or even that of the General Medical Council may well be called.*" I beg to state that, as published in the *British Dental Journal* of Oct. 31st last, the attention of the Council was called to the same advertisement appearing in another paper (*Answers*) and the only reply given by the Registrar was that "according to the regulations of this Council, any complaint as to improper advertising is duly considered." A correspondent of ours, Mr. L. Strangways-Hounsell, L.D.S. Eng., communicated later with the Royal College of Surgeons of England and received a reply from which the following is an extract (*British Dental Journal*, January, 1899):—

> "The Council do not possess any disciplinary powers in regard to their Dental Licentiates so as to enable them to stop advertisements such as the one you so rightly condemn. *The Council* cannot and do not require any undertaking on the part of those who seek the Dental licence in reference to advertising. I can only repeat that I regret, as matters stand, *there is not any redress to be obtained in this matter.*"

It would seem, therefore, that it *is of little* use to call the attention either of the Royal College of Surgeons or of the General Medical Council to an advertisement which is in flagrant violation of professional etiquette.—I am, Sirs, yours faithfully,
THE EDITOR OF THE "BRITISH DENTAL JOURNAL."
Weymouth-street, W., Feb. 28th, 1899.

*** We intend to join forces with the editor of our contemporary and see if this and similar advertisers cannot be prevented from disgracing the medical and dental professions.—ED. L.

STERILISATION AND THE TYPHOID BACILLUS.

To the Editors of THE LANCET.

SIRS,—Are we correct or are we not in our general belief that sterilisation of milk (usually used within a few days of the process being carried out) renders it absolutely free from any risk as to the vitality of any *enteric germs it may have contained?* I would ask for some authoritative pronouncement from our bacteriologists because I find that a paragraph going the rounds as to some American experiments of Messrs. Bolley and Fields (U.S. Government analysts) is having a very disquieting effect on the average hard-working, too-busy-to-read-much practitioner. You will know. It is stated that "typhoid bacteria can exist for upwards of four months in sterilised milk, and in butter (uncleansed of whey) for three months." Surely not?

I am, Sirs, yours *faithfully*,
FREDK. A. LEES, L.R.C.P. Lond., M.R.C.S. Eng.
Leeds, Feb. 27th, 1899.

*** In properly sterilised milk no enteric germs can be present unless it has been subjected to contamination after the process.—ED. L.

"A GENTLEMAN" AND HIS METHODS.

To the Editors of THE LANCET.

SIRS,—Your advice is so good on all matters connected with the medical profession that I may be pardoned for troubling you for it under the following circumstances. "A gentleman," L.S.A. Lond., recently sold a nucleus by means of cooking the books, making false entries &c., by which he represented that he was making £3 per week when in reality he was only taking about 15*s*. He at the same *time sold* the incomer drugs for which he had not paid the wholesale chemists; and here it should be *mentioned*, though it does not strictly concern the medical side of the case, that he left various tradespeople in the lurch and that his taxes were obtained through the instrumentality of the bailiff and a policeman. His wife ordered dresses but neglected to pay for them.

Now, my object is not to drag the name of a defaulting brother, and so the medical profession generally, through the mud before the general public, but simply to prevent the man from continuing to defraud men who can ill afford to throw away money; for I have good reason to believe that this "gentleman" is in the habit of settling in a neighbourhood for a month or two cooking books and selling a bogus nucleus. For this purpose he makes use of your columns and possibly that of your chief contemporary the *British Medical Journal*. The facts which I state are known to my colleagues, and I enclose my name and his. Is there any way by which he can be prevented from carrying on this system of fraud? Can you and do you refuse to insert an advertisement if it should come from what you know to be a questionable source? For this is the only way which occurs to me to stop the fraud.

I fear that I have inflicted a somewhat lengthy letter upon you, but the matter is not entirely devoid of interest to the profession generally, for judging from his last venture he will so far as is possible bring the profession into bad odour wherever he may go.

I am, Sirs, yours faithfully,

Feb. 28th, 1899. D. P.

*** It is impossible for us to know the antecedents of our advertisers and the fraudulent advertisement is always made to read nicely. Where we have any suspicions we always refuse the advertisement until our suspicions are cleared up. We can assure our correspondent that the person in question will have no advertisement inserted in our columns unless he can explain the circumstances of his previous sale-transactions to our satisfaction, giving us also full opportunity to verify his statements.—ED. L.

"SUGAR FREE WINES."

To the Editors of THE LANCET.

SIRS,—We read with very great interest your paragraph and list of "sugar-free" wines contained in THE LANCET of Feb. 25th. You are kind enough to mention our brand of Laurent Perrier, "Sans Sucre," but will you permit us to say that our address is 33, Leadenhall-street, not 17, Billiter-street. It is true that our premises run down Billiter-street, but the entrance is at 33, Leadenhall street. We would further venture to remind you that the words "Sans-Sucre" are our Laurent Perrier trade mark. You in the list apply the words to another champagne as well as to our own and no doubt this has arisen from the fact that this house did some years ago label some small quantity of their wine with the words "Sans-Sucre," but on our drawing their attention to the fact that we had registered these words they courteously consented at once to drop all use of them.—We are, Sirs, yours faithfully,

Leadenhall-street, E.C., Feb. 27th, 1899. HENRY & COLLINGWOOD.

"WHAT IS ADVERTISEMENT?"

To the Editors of THE LANCET.

SIRS,—The newspaper article to which you draw attention has caused me much annoyance, a feeling which would have been still stronger had not its tone appealed so strongly to one's sense of the ridiculous. One morning in the preceding week a gentleman called upon me and professed great interest in the subject of cancer, upon which he desired information for literary purposes. I answered a few questions and for any further details referred him to my published works. He told me that my name would not appear in the papers he proposed to write. I feel sure that no one acquainted with me will credit me with responsibility for the grotesque manner in which my name has been introduced or for the palpably absurd statements to which you rightly object.

I am, Sirs, yours faithfully,

HERBERT SNOW.

Gloucester-place, Portman-square, W., Feb. 27th, 1899.

*** We publish this letter with much pleasure. It will be seen that the representative of the *Echo* is stated by Dr. Snow to have obtained the interview upon false pretences and then to have broken faith with he interviewed. We understand that in some circles many things which are obviously bad manners get themselves accepted as "good journalism," but the representative of the *Echo* stands accused of more than bad manners.—ED. L.

A MEDICAL LADY'S FEES IN DISPUTE.

THE Brussels courts have had to adjudicate for the first time upon the reasonableness or otherwise of the fees claimed by a medical lady. The circumstances of the case were briefly as follows. A certain baron applied to the court for a separation from his wife on the ground of her persistent refusal of marital rights. This application being granted the lady, who was a devout Catholic, applied to the ecclesiastical authorities for a declaration of nullity of marriage, stating at the same time her desire to take the veil. The case was sent to Rome by the Archbishop of Malines and leave obtained for the lady to *enter a convent* on condition of proof being furnished that the marriage had never been consummated. For this purpose recourse was had to a certain medical lady who examined her and declared on oath before the ecclesiastical court that the baroness was still *virgo intacta*. The fee claimed by the lady doctor was 1000 francs which was refused on the ground that it was far more than would have been asked by the most eminent male members of the profession in Brussels. The explanation given was that it covered a large amount of work, several visits to the baroness, two journeys to Spa, one to Malines, a written report, and giving evidence before the ecclesiastical authorities. Also that the opinion of the Medical Commission had been taken upon it and that that very *important professional* body had considered the amount suitable. The court, however, reduced it by one-half—i.e., to 500 francs.

◆

L. J.—All communications should be addressed to the honorary secretary of the National Association for the Prevention of Consumption and Other Forms of Tuberculosis at 20, Hanover-square, London, W. The association consists of ordinary and of life members. The subscription of ordinary members is 5s. annually. A donation of five guineas qualifies for life membership. The object of the association is the prevention of tuberculosis and the methods to be adopted to this end are threefold: 1. The education of public opinion and the stimulation of individual initiative by means of (*a*) a central office for the collection and distribution of information as to modes of diffusion of tuberculosis and measures of prevention; (*b*) the circulation of pamphlets and leaflets setting forth in plain language the results of scientific investigation of the above points; (*c*) public lectures by men approved by the council, addresses at congresses and other public gatherings; (*d*) coöperation with other societies having for their object the promotion of public health; (*e*) the coöperation of the public press; (*f*) periodical congresses and the issue of an annual report; and (*g*) the promotion of the establishment of open air sanatoria for tuberculous patients. 2. The influencing of Parliament, county councils, boards of guardians, chambers of agriculture, and other public authorities on matters relating to the prevention of tuberculosis. 3. The establishment throughout the kingdom of local branches of the association.

Asterion.—From the circumstances as stated by our correspondent B certainly has a right to charge a fee, but we do not know what the rules of the institution may be with regard to A engaging in private practice. If A by any by-law of the dispensary or by the general tenor of the rules may not attend private patients he clearly should not charge fees. We would suggest that A should talk the matter over with B's usual medical adviser and take his opinion on making a charge and on what charge to make.

L. V. Sc., L.M., and S.—The Bombay Municipal Act would seem to be one thing and the Infectious Diseases Notification Act of Great Britain another. Under the latter there are certain duties to be discharged and certain fees attached; under the former there is a duty but apparently no fees. The position does not on the face of it seem quite fair, but the only remedy is repeal or alteration.

J. D.—1. There are several excellent apparatus on the market for the purpose. One convenient form is described in THE LANCET of Feb. 12th, 1898.—2. Boiling destroys tubercle bacilli with certainty.—3. The Report of the Royal Commission on Tuberculosis and Milk-Supply (Government Blue Book), published by Eyre and Spottiswoode, East Harding-street, E.C.

Physical can only consult a good surgeon or physician. He cannot find out what the board's decision will be beforehand.

Hornchurch is advised to do nothing.

During the week marked copies of the following newspapers have been received: *Eastern Daily Press*, *Devon and Exeter Gazette*, *Chester Chronicle*, *Western Morning News*, *Times of India*, *Pioneer Mail*, *North British Daily Mail*, *Hampstead Record*, *Sheffield Telegraph*, *Scotsman*, *Architect*, *Citizen*, *Builder*, *Cambridge Chronicle*, *Western Daily Press*, *Chemist and Druggist*, *South Wales Echo*, *Bath Herald*, *St. James's Gazette*, *Cork Herald*, Umpire, *Yorkshire Post*, *Leicester Daily Post*, *Warrington Guardian*, *Liverpool Daily Post*, *Leeds Mercury*, *Brighton Gazette*, *Bristol Mercury*, *Northern Whig*, *Manchester Guardian*, *Blackburn Telegraph*, *Clifton Chronicle*, *Oswestry Advertiser*, *Huddersfield Chronicle*, *Sanitary Record*, *Commercial Intelligence*, *Temperance Chronicle*, *Wakefield Sentinel*, *Grimsby Telegraph*, *Madras Times*, *Hertfordshire Mercury*, *City Press*, *Local Government Chronicle*, *Bournemouth Guardian*, *Reading Mercury*, *Mining Journal*, *Scottish Guardian*, *Public Health Engineer*, *Surrey Advertiser*, *Newtownards Chronicle*, *Kent and Sussex Courier*, *Halifax Guardian*, *Australasian Medical Gazette*, *Echo*, *Local Government Journal*, *North-Eastern Daily Gazette*, *Evening Telegraph*, *Middlesbrough*, *Yorkshire Herald*, *St. Mary's Hospital Gazette*, *Cheltenham Examiner*, &c., &c.

Communications, Letters, &c., have been received from—

A.—Dr. J. Althaus, Lond.; Mr. H. S. Anderson, Dunmurry; Mons. J. Astier, Paris; Messrs. Allen and Hanburys, Lond.; Alliance Assurance Co., Secretary of; Mr. W. Andrews, Lond.; Mr. J. R. Armstrong, Treorchy.

B.—Dr. F. Bushnell, Plymouth; *British Dental Journal*, Editor of; Messrs. Burgoyne and Burbidges, Lond.; Mr. V. O. Bensley, Peterborough; Mr. W. H. Battle, Lond.; Bristol Sanitary Authority; T. B. Browne, Ltd., Lond.; Dr. A. G. Bagshawe, Buxton; *Birmingham Medical Review*, Publishers of; Messrs. Brampton, Birmingham; Dr. E. S. Breyfogle, San Francisco; Borough of Douglas, Town Clerk of; Mr. C. Birchall, Liverpool; British and Foreign Oxolin Co., Lond.; Dr. John Brunton, Lond.; Messrs. A. and C. Black, Lond.

C.—Mr. G. A. Clarkson, Leicester; Dr. Austin Cooper, Lond.; Mr. E. Treacher Collins, Lond.; Mr. H. F. Cheese, Lond.; Mr. N. Close, Chard; Mr. T. S. Cotterell, Bath; Dr. W. H. Campbell, Rush Springs, U.S.A.; Chelsea Hospital for Women; Cortland Wagon Co., Lond.; Messrs. E. Cook and Co., Lond.; Coventry and Warwickshire Hospital, Secretary of; County Asylum, Whittingham, Superintendent of; Messrs. A. H. Cox and Co., Brighton; Messrs. J. W. Cooke and Co., Lond.; Cumberland Infirmary, Carlisle, Secretary of; Messrs. H. and W. Cox, Leicester; Messrs. Crossley, Moir, and Co., Lond.; Messrs. W. H. and L. Collingridge, Lond.; Mr. Watson Cheyne, Lond.; Cui Bono.

D.—Mr. *H. Drewry, Nottingham*; Messrs. Davy Hill and Co., Lond.

E.—Mr. G. W. Ellis, Bishop Auckland; Dr. R. C. Elsworth, Swansea.

F.—Messrs. Ferris and Co., Bristol; Messrs. J. S. Fry and Sons, Bristol; F.R.C.P.; Mr. W. K. Fulleylove, Nuneaton; Dr. F.

G.—Messrs. W. Gaymer and Sons, Attleborough; Great Northern Central Hospital, Lond., Secretary of; *Gaillard's Medical Journal*, New York, Publishers of.

H.—Dr. W. K. Hunter, Glasgow; Mr. E. Huxley, Lond.; Dr. A. Haig, Lond.; Mr. J. T. Hislop, Harrogate; Mr. J. Heywood, Manchester; H. M.; Mr. W. A. Hewitson, Durham.

I.—Irish Club, Lond.

K.—Dr. R. Kirk, Glasgow; Messrs. R. A. Knight and Co., Lond.

L.—Mr. E. W. Lamb, Crewkerne; Mr. H. K. Lewis, Lond.; Luxor Hospital for Natives, Egypt; L. C.; Mr. E. M. Little, Lond.; London Association for the Prevention of Premature Burial; Mr. J. Lewis, Lond.

M.—Mr. E. Merck, Lond.; Mr. E. Morgan, Newtown; Mr. W. Monckton, Portishead; Dr. J. Macintyre, Glasgow; Dr. G. R. Murray, Newcastle; Dr. W. R. Manders, Stockport; Messrs. J. Maclehose and Sons, Glasgow; Mr. A. MacGregor, Lond.; Mr. A. Mottram, Norwich; Messrs. Macmillan and Co., Lond.; Matto, Ltd., Lond.; Maltine Manufacturing Co., Lond.; Metropolitan Machinists' Co., Lond.; Mr. R. Montgomery, Dublin; Mr. J. Murray, Lond.

N.—Norwich Medico-Chirurgical Society, Hon. Secretary of; New Hudson Cycle Co., Birmingham.

O.—Dr. Oppenheimer, Lond.; Mr. F. Orchard, Lond.

P.—Dr. J. Penny, Manchester; Pennsylvania University, Philadelphia, Librarian of; Dr. J. E. Platt, Manchester; Mons. G. Popp, Paris.

Q.—Queen Charlotte's Hospital, Secretary of.

R.—Dr. J. S. Riddle, Aberdeen; Royal Ear Hospital, Lond., Hon. Secretary of; Royal College of Surgeons in Ireland, Registrar of; Dr. Henry Rundle, Southsea; Mr. Leonard Rea, Lond.; Dr. A. Ruffer, Baroda, India; Ross, Ancrum; Dr. J. Ryan, Finnea; R. B.; Dr. R.; Dr. Ford Robertson, Edinburgh.

S.—Mr. Howard Spalding, Lond.; Messrs. Smith, Elder, and Co., Lond.; Mr. C. D. Somers, Surbiton; Sanitas Co., Lond.; Messrs. H. C. Scales and Co., Lond.; South Devon and East Cornwall Hospital, Plymouth, House Steward of; Stockport Infirmary, Secretary of; Mr. E. F. Smart, Bristol.

T.—Dr. E. F. Trevelyan, Leeds; Mr. W. Thelwall Thomas, Liverpool; Mr. W. Toogood, Lond.

V.—Dr. G. R. Vicars, Wood Dalling; Vineyard Basket Wine Co., Lond.; Victorian Eye and Ear Hospital, Melbourne, Secretary of; Mr. E. Woodhouse Veale, Bristol.

W.—Mr. S. Wand, Leicester; Mr. Wells, Lond.; Messrs. J. Wright and Co., Bristol; West Bromwich District Hospital, Secretary of; W. S., Cahir.

X.—X. Y. Z.

Y.—Mr. C. A. Young, Hertford; Mr. T. Younghusband, Lond.; Dr. Yellowlees, Edinburgh.

Letters, each with enclosure, are also acknowledged from—

A.—Mr. F. O. Auger, Chatham; A. W.; Mr. R. R. Anderson, Fern Hill; Mr. F. C. Abbott, Lond.; Ancoats Hospital, Manchester; Dr. J. Adam, West Malling; Messrs. C. Ash and Sons, Lond.; Mr. W. Adams, Lond.; Sir E. Ackroyd, Hove; Dr. Adams, Barnes.

B.—Mr. J. Boot, Nottingham; Mr. J. Barr, Bolton; Mr. A. E. Broster, Wirksworth; Mr. R. S. Betts, Bournemouth; Mr. A. J. Brodie, Bournemouth; Messrs. F. L. Borthwick and Co., Lond.; Mr. H. H. Ballachey, Chelford; Mr. R. Bebb, Ton Pentre; Dr. R. L. Bowles, Lond.; Messrs. Buchner, Schacht, and Co., Lond.

C.—Mr. W. L. Crowdy, Lond.; Cardiff Infirmary, Secretary of; Mr. W. T. Clarke, Morley; Miss Colclough, Lond.; Dr. E. F. Cyriax, Stockholm; *Canada Lancet*, Toronto, Manager of; Mr. F. W. Clarke, Chorlton-cum-Hardy; Dr. R. Craik, Conisborough; Mr. R. Cresswell, *Woolacombe*; *Cantab*, Lond.; Mr. J. B. Cameron, Lond.; Dr. J. Crawford, Walworth; C. C. B.; C. E. M. K.; C. W. J. D.; Mr. L. Cobbett, Cambridge; Messrs. Clarke, Son, and Platt, Lond.; C. E. J. S.

D.—Mr. W. F. Dale, Welling; Major G. W. P. Dennys, Sialkot, India; D. J. R.

E.—Dr. W. Ewart, Lond.; Mr. H. Eccles, Bishop's Stortford; Mrs. Easly, Lond.; E. H. M.; E. S. S.; Mr. F. Edwards, Sawston; E. R.; E. M. S.

F.—Mr. D. B. Foley, Wombwell; Mr. W. J. Furnival, Stone; Mr. J. J. Fraser, Clitheroe; Dr. F. D. Fisher, Ossett; F. G. C.

G.—Mr. T. M. Giffen, Chester; Messrs. Grimwade, Ridley, and Co., Lond.; Glasgow Royal Infirmary, Cashier of; Mr. H. W. Gordon Greene, H.M.S. *Imperieuse*, Esquimalt; Miss G., Lond.; Mr. B. Gowing, Droitwich; Messrs. Gordon, Alexander, and Co., Glasgow; Drs. Green and Rose, South Norwood.

H.—Mr. J. H. Hadden, Lond.; Dr. J. T. Harvey, Broken Hill; High Shot House, Twickenham; Dr. H. Hunter, Ashburton, New Zealand; Halifax Union, Clerk of; Mr. T. M. Hocken, Dunedin, New Zealand; Dr. J. Hussey, Farnham; Mr. G. Harvey, Wirksworth; H. D. C.; Dr. C. Haslewood, Prescot; Hovis Bread Flour Co., Lond.; Messrs. Hooper and Co., Lond.

J.—Jenner Institute for Calf Lymph, Lond., Secretary of; Messrs. Johnson and Jörgensen, Lond.; J. J. F.; J. H. D.; J. E. A.; J. C. C.; J. W. D.; J. P. W.; J. R., Liverpool; J. L. B.

K.—Professor S. Kitasato, Nishino-Kubo, Japan; Dr. A. Kay, Motherwell.

L.—Dr. A. E. Larking, Folkestone; London Agency for Masseuses, Secretary of; L. L.; L. W. K. T.; Dr. H. A. Lawton, Poole.

M.—Mr. R. P. Merry, Hemel Hempstead; Mr. W. A. Mushé, Lond.; Dr. S. G. Morris, Croydon; Mr. H. Morris, Lond.; Messrs. Murley Bros., Lond.; Mysore Government, Senior Surgeon of; Mr. W. L. W. Marshall, Huddersfield; Dr. J. McLintock, Slaniannan; Medicus, Manchester; Mr. W. H. Maidlow, Ilminster; Mr. H. Mackay, Derby; M.R.C.S.; Dr. W. B. Morton, Brislington; Mr. J. Milne, Ladywell; M.D., Manchester; M. J.; M. P. C.

N.—Dr. A. G. Naylor, Chesterfield.

P.—Mr. H. L. *Palmer, Newtown*; Dr. J. C. Potter, Spennymoor; Dr. D. J. Parry, Pontycymmer; Dr. Packer, Cressage; P. A., Lond.

R.—Mr. W. C. Ross, Fence Houses; Royal Surrey County Hospital, Guildford, Assistant Secretary of; Messrs. Roger and Chernoviz, Paris; Dr. W. Ross, Hartlepool; Dr. T. H. Redwood, Rhymney; R. W. M.; R. E. F.; Royal National Hospital for Consumptive, Ventnor, Secretary of; Robertson, Liverpool; Roxburgh District Asylum, Melrose, Secretary of; Royal United Hospital, Bath, Secretary of.

S.—Mr. J. E. Sharpley, Kirton-in-Lindsey; Mr. L. Stone, Newcastle, Ireland; Dr. A. B. Squire, Lond.; Springfield House Asylum, Bedford, Medical Superintendent of; Dr. D. M. Stevenson, Bradford; Mr. *R. H. Sharples, Lond.*

T.—Dr. Turner, Felixstowe; The Thorn, Hayes; T. E. G.; T. T.

V.—Dr. A. H. H. Vizard, H.M.S. *Urgent*, Jamaica; V. E. B.

W.—Mr. J. A. Wood, Bourton-on-the-Water; Welsh Calvinistic Methodist Foreign Missionary Society, Liverpool, Secretary of; Mr. R. L. Woollcombe, Dublin; Dr. J. Wilson, Liverpool; W. R., Darlington; Mr. F. F. Wellington, Lond.; W. M. R.; Dr. W. S. Whitcombe, Aldermaston; West, Cheltenham; Mr. B. Wheeler, Manchester; W. B.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

The Goulstonian Lectures

ON

THE PATHOLOGY OF THE THYROID GLAND.

Delivered before the Royal College of Physicians of London

By GEORGE R. MURRAY, M.A., M.D. CANTAB., F.R.C.P. LOND.,

HEATH PROFESSOR OF COMPARATIVE PATHOLOGY IN THE UNIVERSITY OF DURHAM; PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE.

LECTURE I.[1]

Delivered on March 7th, 1899.

MR. PRESIDENT AND GENTLEMEN,—I must, in the first place, thank you very sincerely for the honour which you have conferred upon me by asking me to deliver the Goulstonian Lectures for this year, an honour which I feel to be all the greater when I read the list of distinguished Fellows of this College who have preceded me in this lectureship in whose footsteps I can but humbly endeavour to follow.

GENERAL SCOPE OF THE LECTURES.

In selecting the subject for these lectures I have been guided by three considerations. First, the wide-spread interest which has been aroused in the pathology and treatment of diseases of thyroid gland during the last few years. Secondly, the good example which the subject affords of how experimental research in pathology yields results which are of the greatest importance and assistance to the physician in his daily work of treating disease. Thirdly, the opportunity which I have had of devoting some attention to the subject may, I venture to hope, enable me to present it in a manner which will interest you. I shall not attempt to cover the whole ground but shall for the most part deal with those parts of the subject which I have been able to examine for myself, nor will time permit me to allude to all the valuable work which has been done by the many workers in this branch of pathology. I trust, therefore, that this explanation will excuse any omissions which I may make in not referring to the work of others.

It will be convenient first to consider the development and structure of the thyroid gland and the method in which its characteristic secretion is produced. This will clear the way for the consideration of the results which follow when this function is diminished or lost by removal of the gland in animals or by its destruction by disease in man. The removal of the thyroidal insufficiency thus induced by maintaining a supply of secretion from other sources will be considered as a means of treatment. I propose also to deal with the question of compensatory hypertrophy as illustrated by the thyroid gland, while in conclusion the pathology of exophthalmic goitre will be considered as far as our present knowlege of the subject permits.

DEVELOPMENT AND STRUCTURE OF THE THYROID GLAND.

The embryology and comparative anatomy of the thyroid gland furnish us with important information as to the origin of its present situation, structure, and function in man. The gland is developed in the embryo in three different parts. A median diverticulum of the hypoblast which lines the pharynx of the embryo is formed between the ventral ends of the second visceral arches, while a lateral diverticulum is developed on each side from the posterior wall of the fourth visceral cleft. In man the median portion persists for a time as a hollow vesicle from which a small canal, the thyreoglossal duct, leads to an opening on the dorsal surface of the tongue. At a later stage this vesicle becomes solid and the duct disappears, while its external opening on the surface of the tongue persists as the foramen cæcum in the adult. The two lateral diverticula fuse with the central portion, forming a mass shaped like a horseshoe encircling the embryonic larynx. All three portions become separated from the hypoblast from which they originated and develop into a mass of branching cell-cylinders. These cell-cylinders are later divided up by the ingrowth of connective tissue containing blood-vessels into separate vesicles. These gradually increase in size and become hollowed out by the accumulation of the colloid substance which is secreted by the epithelial cells into the lumen of the alveolus. His[2] has found that in some cases the thyreoglossal duct already mentioned does not become obliterated, but that it persists in the adult as the lingual duct which has been traced from the foramen cæcum as far down as the hyoid bone. In some cases the middle lobe of the gland is continued upwards as a narrow tube, the thyroid duct, as far as the hyoid bone. The late Professor Kanthack,[3] who examined 100 adults for these ducts, however, found neither a lingual nor a thyroid duct in any of the cases which he investigated and in many there was not even a foramen cæcum. The important fact remains that the thyroid gland is developed primarily as an outgrowth of the pharyngeal hypoblast, and in some lower animals this connexion with the pharynx is still maintained. Andriezen[4] directed attention to the fact that the thyroid gland is represented in ascidians by a mass of glandular tissue and in amphioxus by a hypobronchial organ which pours its secretion directly into the pharynx. In higher forms (such as fishes) the gland is embedded in the surrounding tissues but the duct which communicates with the pharynx still remains. Thus both the ontogenetic and phylogenetic histories clearly show that the gland as we now find it in man is descended from a secretory gland which originally was provided with a duct through which the secretion passed into the pharynx just as the secretion of the salivary glands still flows into the mouth. In this we find an explanation of the fact that the activity of the thyroid secretion is not destroyed by passage through the stomach but still can produce all its usual physiological effects when swallowed and absorbed from the alimentary canal as it doubtless was by our remote ancestors. This mode of evolution seems to indicate that a ductless gland with an internal secretion is a higher stage of development of a duct gland with an external secretion.

The fully developed gland consists of three parts—two lateral lobes and the isthmus which unites them. The two lobes are closely applied to the sides of the larynx and trachea and extend backwards as far as the sides of the pharynx and œsophagus. At the level of the isthmus the recurrent laryngeal nerve lies in the angle between the œsophagus and the trachea, being covered externally by the lateral lobe of the gland on each side. In front the gland is covered by the sterno-hyoid, the sterno-thyroid, and omo-hyoid muscles. Laterally the lobes extend outwards in front of the common carotid arteries. Each lateral lobe is shaped somewhat like an almond but the upper end is narrower and more pointed than the lower. The lower end lies on the fifth or sixth ring of the trachea, while the upper is generally on a level with the middle of the thyroid cartilage. The position of the isthmus varies, but it generally lies in front of the second, third, and fourth rings of the trachea. In many cases, variously estimated at from 40 to 68 per cent., the pyramid or middle lobe extends as a thin process from the isthmus or from a neighbouring part of one of the lateral lobes up to the hyoid bone to which it is attached by muscular or fibrous tissue. The gland is firmly fixed to the larynx and trachea by fibrous tissue so that it follows the movements of these structures which take place during deglutition. The gland when freshly removed is of a dark red-brown colour. It usually weighs from an ounce to an ounce and a half (from 30 to 50 grammes). It is relatively larger in the infant than in the adult; thus Huschke and Weibgen[5] found that in newly-born children the weight of the gland was equal to from $\frac{1}{400}$ to $\frac{1}{500}$ and in adults from $\frac{1}{1222}$ to $\frac{1}{1800}$ of the total weight of the body. The gland is as a rule somewhat larger in women than in men, though Ewald[6] makes a contrary statement supported by Weibgen who gives the average weight in the male as 34·2 grammes, and in the female as 29·3 grammes. Each lobe is about two inches (50 mm.) long, an inch and a quarter (30 mm.) broad, and three quarters of an inch (18 mm.) deep. The right is generally a little larger than the left. The isthmus is about half an inch (12 mm.) broad, and from a quarter to three quarters of an inch deep. The whole gland, however, is liable to considerable variations in structure, such as inequality in size between the two lobes, absence of one lobe, and absence or irregularity of the isthmus. There is a rich blood-supply from four arteries, the superior and the inferior thyroid arteries on each side, and in some cases there is a further supply by the thyroidea ima. These arteries are tortuous and very large for the size of the gland which they supply; they form many anastomoses and finally end in a network of capillaries closely surrounding each alveolus. The capillaries come into close relationship with the epithelial cells and some capillary loops even project between them. The veins which, according to Sappey, have no valves unite to form the superior, middle, and inferior thyroid veins, the two former of which open into the internal jugular vein while the latter enters the innominate. The lymphatics start from the lymph spaces in the connective tissue which surrounds and unites the vesicles of the gland. They unite to form large trunks which freely anastomose both in the substance of the gland and also upon its surface. On leaving the gland the lymphatics pass through the superior and inferior deep cervical glands to join the jugular lymphatic trunk, which on the left opens into the thoracic duct and, on the right into the right lymphatic duct, each of which discharges into the venous blood-stream at the point where the innominate vein is formed by the junction of the internal jugular and subclavian veins on each side. The nerves which supply the gland come from the middle and inferior cervical sympathetic ganglia and pass into it with the blood-vessels. The nerve branches run in close proximity to the bases of the epithelial cells but the actual nerve-endings have not yet been described.

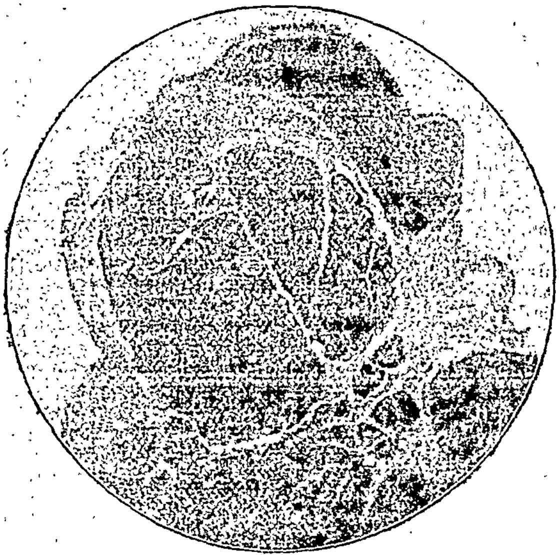
HISTOLOGY.

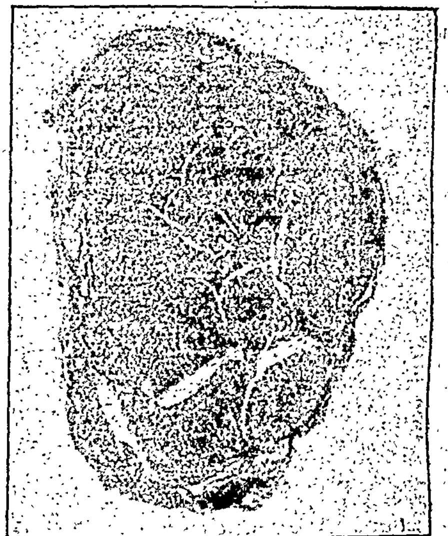
Externally the gland is invested by a firm fibrous capsule from which septa extend inwards, partially dividing it into lobules of various sizes. Still finer divisions of this connective tissue framework surround the individual follicles and support the small divisions of the blood-vessels, lymphatics, and nerves. The glandular structure consists of large numbers of closely aggregated follicles which vary in size and shape. On section they appear round, polyhedral, or flattened, and the diameter in man ranges from 0·045 mm. to 1 mm. In the great majority of the follicles there is a single layer of cubical epithelial cells surrounding a central area filled with their secretion, the colloid substance. Some of the follicles seen in a section of the gland appear as masses of cubical cells without any central space. This appearance is in some cases due to one side of the alveolus alone being exposed in the section; in others to the alveolus not being distended with secretion. No basement membrane to the epithelium has been described. Two kinds of cells are found in the epithelium—the chief cells and the colloid cells. The chief cells are usually cylindrical, sometimes cubical, in shape. They measure from 8 μ to 16 μ in height and from 6 μ to 8 μ in breadth, while the nucleus which is round measures from 5 μ to 6 μ in diameter. The colloid cells are considerably shorter than the chief cells, thus Hürthle[7] found in one specimen that while the chief cells measured from 12 μ to 14 μ in height the colloid were only from 7 μ to 9 μ high. The colloid cells are also distinguishable from the chief cells by the readiness with which they take up those staining fluids which also stain the colloid substance in the centre of the follicle. Intermediate types may also be observed. The colloid substance which occupies the central space of the alveolus is a yellow glairy fluid which stains uniformly in microscopical sections. Scattered through it may sometimes be seen white blood corpuscles, epithelial cells, and the remains of red blood corpuscles undergoing degenerative changes. The general appearance of the gland is shown in Fig. 1 and Fig. 2, which were taken from transverse sections through the lateral lobe of the thyroid gland of a bonnet monkey. These and the other micro-photographs which will be shown later have been kindly prepared from my specimens by Dr. R. A. Bolam. These illustrations also show how closely in this animal the parathyroid is attached to the thyroid gland in which it may be even partly embedded, as in Fig. 2, an association to which I shall refer more fully in dealing with the functions of the gland.

FIG. 1.



Transverse section of thyroid gland of bonnet monkey, showing general structure and close attachment of parathyroid gland.

FIG. 2.



Transverse section of one lobe of thyroid gland of monkey, showing one portion of parathyroid at right edge of section and another triangular portion embedded in and just below centre of thyroid gland.

FORMATION AND ABSORPTION OF THYROID SECRETION.

The colloid substance is the secretion of the epithelial cells which line the alveoli. Hürthle has shown by observations made on normal glands and on portions of glands in which increased secretory activity had been stimulated either by removal of the greater part of the gland or by ligature of the bile-duct so as to cause absorption of bile-products into the blood that the secretion may be formed by the epithelial cells in two ways. The colloid may be either formed in droplets in the cells and then gradually extruded into the lumen of the alveolus or whole cells may break down and be discharged into the colloid substance, a part of which they thus help to form. In the first method the same cell continues to secrete, while in the second its place is taken by one of the reserve cells. It is doubtful if both these methods obtain during normal secretion, the first being probably the usual manner in which secretion takes place. The large amount of secretion which is found in many alveoli indicates that under ordinary circumstances it is not discharged as soon as it is formed, but that the central portion of the alveolus serves as a reservoir where the secretion is stored for a time before it finally escapes from the gland.

---

[7] Pflüger's Archiv, 1894, vol. lvi. 1.

As the thyroid is a ductless gland it is clear that the secretion can only escape by the lymphatics or the veins. The evidence which we possess shows that the former is the usual path, for it was shown by King and by Horsley[8] that by applying pressure to the gland the colloid could be squeezed from the acini into the interacinous lymphatic spaces where it could be seen with the microscope. Biondi and Hürthle have found that this escape of the secretion from the alveolus may occur in two ways. The walls of the alveolus, not necessarily as the result of distension, becomes thinned out at one point and finally ruptures, allowing the colloid to escape directly into the lymphatic space outside while the empty follicle collapses and forms the starting-point for a new one. Hürthle has found that the secretion can also pass out from the alveolus without rupture of the wall. He injected Berlin blue into the lymphatic spaces of the gland, using an intermittent pressure, and found that it passed on into the interior of the alveoli through minute intercellular channels in which it could be seen. He also found that when the secretory activity was stimulated the colloid itself could be seen lying in these intercellular channels continuous with the colloid in the alveolus at one end and with that filling the lymph spaces at the other, proving that it was passing from the former position to the latter. By one or other of these methods, then, the secretion flows into and mingles with the lymph which bathes the interalveolar spaces of the gland and with it flows along the path already described to be discharged into the blood stream in the innominate vein and so distributed to all parts of the body. No doubt as in other glands the activity of the secretion varies according to circumstances; of these, however, we possess but little information. Stimulation of the laryngeal nerves or of the sympathetic with the faradaic current produces no change indicative of increased secretion. Pilocarpin produces a marked increase in the secretion of the colloid as shown by Wyss, and Schäfer found that the changes produced in the cells were similar to those which occur in other secretory glands under the stimulating influence of this drug. As already mentioned the presence of an excess of bile constituents in the blood after ligature of the bile duct also stimulates thyroidal secretion. Removal of the greater part of the gland was also shown by Hürthle to serve as a stimulus to more active secretion in the remaining portion.

COMPOSITION OF THYROIDAL SECRETION.

At one time the thyroid gland was considered to be an excretory rather than a secretory gland and the excretion a mucinoid substance the retention of which led to an accumulation of mucin in the body and the production of the subcutaneous swelling in myxœdema. Further investigation has shown that the colloid substance is a true secretion which does not contain mucin. Our knowledge of the actual composition of this secretion is by no means complete but several important constituents have now been separated from it. Most of those who have examined the composition of the secretion have considered the proteids to be the important and active constituent of it. Notkin[9] regards thyreoproteid, a substance which he isolated from the gland, as an active constituent which behaves like an enzyme. Gourlay[10] found that a nucleo-proteid was the only proteid to be obtained from the thyroid in any quantity and that it contained phosphorus which by Morkutun's analysis has been shown to amount to 0·32 per cent. Baumann and Roos[11] made the important discovery that the colloid substance contains iodine in an organic combination with proteid which they named "thyroiodin." This substance contains 9·3 per cent. of iodine and 0·56 per cent. of phosphorus. Hutchison[12] has found that two proteids are contained in the gland, a nucleo-albumin which is contained in the epithelial cells and a colloid material which fills the acini. The formed secretion of the gland is split up by gastric digestion into two parts, one of which is proteid, contains only a small amount of iodine, and has but slight physiological action, the other of which is non-proteid, contains more iodine and all the phosphorus of the original colloid, and is more active in removing symptoms due to loss of thyroid secretion than the proteid portion. S. Fraenkel[13] obtained a crystalline substance with the formula $C_6H_{11}N_3O_5$ from the gland which he named "thyreoantitoxin"; there is, however, no satisfactory evidence to show that this body is endowed with active properties.

It is evident from these observations that the secretion is a complex body and we cannot as yet say whether its remarkable properties depend on one or, as is more probable, several constituents. Be this as it may we shall now consider what functions are fulfilled by the secretion as a whole, for that is the form in which it mingles with the blood and is thereby conveyed to the tissues.

THE RESULTS OF LOSS OF THE SECRETION IN ANIMALS.

A large amount of valuable information as to the properties and functions of this secretion has been obtained by observing what occurs when it is no longer present in the blood. This state of affairs is easily brought about by removal of the gland from an animal. Owing to the superficial position of the gland in the neck this operation can easily be performed so as to entail no other secondary result than the loss of thyroid secretion forthwith, provided only that the parathyroid glands are not attached to the gland and removed with it, in which event the effects observed are the results of thyroidectomy plus parathyroidectomy. In man the results of failure of the normal supply of thyroid secretion from disease of the gland are seen in primary myxœdema and from removal of the gland for goitre in secondary myxœdema or "cachexia strumipriva" as it is also called. My own observations of the results of thyroidectomy have been made on rabbits and monkeys. It has, however, been shown that although no effects have been observed in fishes, in lizards and snakes the operation is followed by loss of strength and activity, ending in death in the course of a few weeks. In rabbits the different results obtained by various observers were difficult to explain until it was shown by Gley[14] that removal of the parathyroid glands along with the thyroid gland produced different effects from the removal of the thyroid alone. The double operation was followed by acute symptoms, the most important of which were muscular tremors commencing in the masseter muscles, clonic and often tetanic contractions of the voluntary muscles, paralysis of the extensors of the fore feet followed by that of the hind limbs, difficult and often rapid respiration, salivation, dilation of the pupils, and rise in temperature. Removal of the thyroid gland alone was followed by no such immediate effects.

My own observations show that although the immediate effects of thyroidectomy are very slight, after a long interval a chronic cachexia develops closely resembling myxœdema in man. Thus in two rabbits which were kept for a long time under observation after the thyroid gland had been removed there was an early development of hebetude and loss of appetite; no further change was noticed until an interval of 11 months in one case and 12 months in the other had elapsed after the operation. After this, in addition to the hebetude already mentioned, swelling of the subcutaneous tissues, dryness of the skin, loss of hair, and subnormal temperature developed—an entirely different condition from that described by Gley after removal of the parathyroids as well. The illustrations show the appearance of one of these animals killed 11 months after the operation and the ears of the other killed 21 months after. The ears were very dry, rough, and cold to the touch though they flushed readily when handled. The edges of the ears were dry and cracked to a depth of a quarter of an inch. In many places this dried margin had broken off, leaving an irregular outline to the ear. In a third rabbit which was kept for 27 months after thyroidectomy no symptoms appeared. When the animal was killed the reason of this was found to be that some of the g tissue had unintentionally been left at the the operation and had undergone compensatory trophy. The total amount of thyroid tissue found only 0·07 gramme or about one-third of the weigh gland of a normal rabbit, but it had been to maintain an adequate supply of secretion for two years. Dogs and cats both develop a rapid cachexia after thyroidectomy. More than 40 Schiff showed that dogs did not long survive the tion and succumbed after total extirpation of the gland. In dogs the total duration of the symptoms induced by the operation may vary from a few days to five weeks, but it rarely exceeds this period. Soon after the operation the animal becomes dull and listless and loses its appetite. These symptoms are followed by fibrillary twitchings in the muscles and clonic convulsions of the trunk and limbs, during which the animal lies on its side with the head thrown back and the limbs extended. There is great dyspnœa during these attacks and the animal is in a half comatose condition which becomes complete before death. There is a general diminution of muscular power and in many cases rapid emaciation. There is a slight rise of the temperature at first which becomes sub-normal before death. The red corpuscles are diminished and the white are increased in number. Very similar symptoms occur in cats. The observations of Vessale and Generali[15] on cats and dogs, of Edmunds[16] on dogs, and of Welsh[17] on cats show that if the parathyroid glands are excised without the thyroid gland very similar acute symptoms occur to those observed when the thyroid and parathyroids are removed together. These symptoms are tremors, slow and unstable gait, emaciation, and weakness, all of which previously were regarded as being due to the loss of the thyroid alone. The most important results of all have been obtained in monkeys which have been employed by Munk, Horsley,[18] and myself. In the bonnet monkey (macacus sinicus) which I have used with one exception in all my experiments[19] a parathyroid gland lies in close connexion with or actually embedded in each lobe of the thyroid gland, as is shown in Fig. 1 and Fig. 2. As a result of this when the thyroid gland is removed the parathyroids are removed along with it. It would be difficult to remove the one without the other, for distinctly as the parathyroid can be seen in a transverse section it is much more difficult to see it during life while the gland is *in situ*. In two recent experiments I was unable to detect even with a lens the parathyroids on either side and to remove them without the thyroid gland; they were, however, easily seen in transverse sections of the lateral lobes after removal of the whole gland. It is therefore important to bear in mind that thyroidectomy in this monkey involves removal of the parathyroids as well, so that the symptoms which occur afterwards are *not* solely due to loss of thyroid secretion but in part are due to loss of the parathyroids as well.

[12] Journal of Physiology, vol. xx., 1896, p. 474.

I have removed the whole or a part of the thyroid gland in nine bonnet monkeys and in one rhesus monkey; in four of the former the symptoms were allowed to develop with the object of testing the influence of various preparations of the thyroid gland upon them. Some symptoms also occurred in the others, but these four form the basis for the description of the symptoms which result from the operation. These symptoms have been very carefully described by Horsley, but they have such an important bearing upon the whole subject that I shall briefly describe what I was able to observe in my own experiments. The gland is readily removed in the following manner when the animal is fully under the influence of ether. The skin of the front of the neck is shaved and carefully washed with one in 1000 solution of perchloride of mercury. A median longitudinal incision is made through the skin overlying the thyroid and cricoid cartilages and upper part of the trachea. On separating the muscles and exposing the upper part of the trachea the isthmus comes into view. Each lobe is then gently separated from the surrounding structures and while the gland is held by one pair of forceps the blood-vessels are torn out of it at the point of entrance by another pair. The loss of blood is trifling and no ligatures are required. The usual antiseptic methods are adopted and the muscles are united by a couple of sutures. The skin is brought together with horsehair sutures set very close. The wound is dressed with carbolic gauze or some antiseptic wool and collodion and it heals rapidly by first intention. After the operation the animals have been kept in a room the temperature of which ranged between 60° and 70° F. In about five days the symptoms first begin to develop, the early symptoms being entirely nervous. One of the first to appear is a fine regular tremor which is most easily seen in the upper limbs but which is also plainly visible in the lower limbs as well when the animal is held with the feet unsupported. Along with the tremor there is a marked change in the whole demeanour which is the more noticeable owing to the naturally lively disposition and active habits of the healthy monkey. There is progressive apathy with loss of natural curiosity and interest in surrounding objects, while the temper is irritable, interference being resented. There is loss of activity, as the animal sits still in one place on a perch or on the floor of the cage for long periods without moving; and there is increasing loss of muscular power, as climbing is done more slowly and evidently with greater effort as the symptoms advance. The attitude assumed is characteristic: the head is bent, the trunk is curved forwards, and the knees are drawn up so that the chin rests upon them, the joints of all four limbs being in a position of flexion. This attitude is well shown in Fig. 3 taken from one of my animals. Contractures owing to tonic spasm of the flexor muscles frequently occur; in fact, this attitude is, I believe, partly a result of these contractures as the limbs are often found to be rigid when it is adopted. Clonic contractions of the muscles are common. There may be a single contraction of a group of flexor muscles or a series of three or four may involve all the flexors of one arm, increasing in intensity until a position of extreme flexion at all the joints is reached, after which relaxation takes place until another series occurs. Irregular fibrillary contractions of the superficial muscles are often visible through the skin. In consequence of these symptoms the gait is stiff and unsteady, and when the contracture is excessive the animal is obliged to walk on the heels owing to the tonic spasm of the flexors of the ankle raising the toes and sole of the foot from the ground. There is a marked tendency to fall over backwards, so that if a banana is held over the animal's head it loses its balance in looking upwards at it and falls over backwards and a very slight push when the animal is sitting has a similar effect. True epileptic fits of greater or less intensity may occur. There may be a sudden loss of consciousness, so that if the monkey is on the perch at the time it falls to the ground. In one case I observed several epileptic fits in succession in which there was loss of consciousness, tonic spasm of the flexor muscles of the limbs, with risus sardonicus, followed by clonic contractions and micturition. In one fit there were in addition double internal strabismus with retraction of the eyelids and conjugate deviation to the left. Retraction of

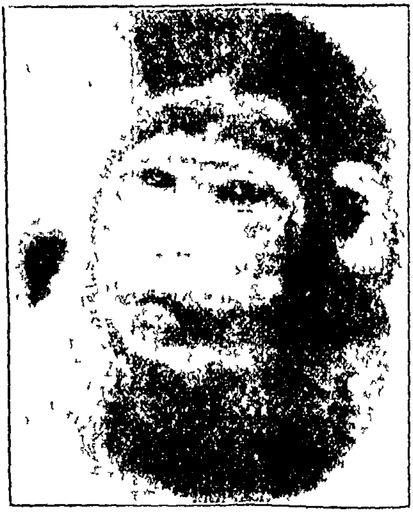
[18] Report of the Clinical Society on Myxœdema, 1888.
[19] The expenses have been partly defrayed by a grant from the Scientific Grants Committee of the British Medical Association.

the head and salivation were also observed I have seen a temporary inability to use the arms owing to spastic rigidity limiting the movement, but not actual paralysis as described by Horsley who twice observed a complete temporary hemiplegia The temperature at first is raised and irregular, but it soon becomes subnormal Thus in one experiment the rectal temperature, which is usually 100°1 in this monkey was only twice below normal during the first week following the operation as it otherwise ranged between 100° and 102° During the second week it only once rose to the normal level being otherwise between 98° and 99 6°, while in the third week it varied between 97 6 and 100°, except on two evenings when it rose to 101° and 102 4° In one experiment I found the temperature as low as 80° four days before death

During the second and third weeks the myxœdematous swelling becomes distinct and as in man is most apparent in the face Both upper and lower eyelids become swollen and with this there is sometimes transverse wrinkling of the forehead Both lips are also swollen by the elastic œdema The appearance of the face is shown clearly in Fig 3 and Fig 4 which were taken from two different monkeys The

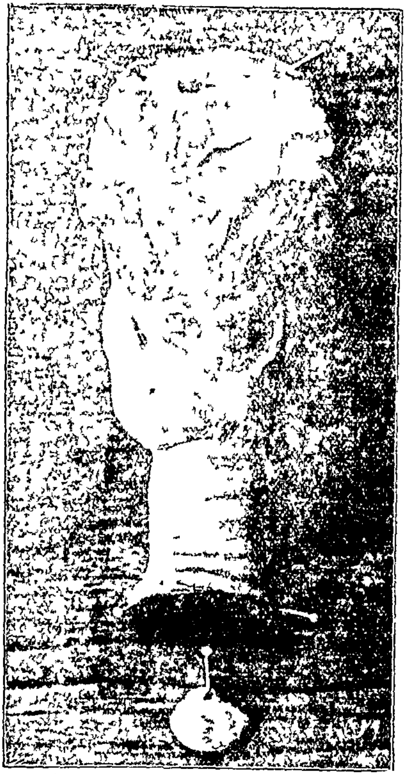
FIG 4



Monkey after thyroidectomy, showing swelling of eyelids and lips

skin more especially of the ears becomes dry and rough and the hair may be shed Examination of the blood shows that the red corpuscles are diminished and the white increased in number The average duration of life was found by Horsley to be 24 days but he showed that when the temperature of the air in the cage was maintained at 90°, the average duration of life was increased to 125 days while the symptoms ran a more chronic course like those of cretinism in man Without giving any further details of this interesting condition its resemblance to primary myxœdema in man is remarkable The course of the symptoms is much more acute than in man, partly because the supply of thyroid secretion is cut off suddenly by the operation, while in primary myxœdema the supply only gradually fails as the disease of the gland advances In both conditions we have the same progressive loss of mental and bodily activity, subnormal temperature, elastic subcutaneous œdema, dry skin, and loss of hair In the monkey we have, however, acute nervous symptoms which do not occur in primary myxœdema though some have been observed after thyroidectomy in man I would suggest, however, from the results of removing the parathyroid glands in rabbits and other animals that these symptoms are in part due to the loss of the parathyroids which, as we have seen, are removed along with the thyroid This view receives further support from the fact which will be considered later, that these acute nervous symptoms are not readily controlled by treatment with thyroid extract as might be expected were they purely thyroidal in origin The close anatomical association of the parathyroid with the thyroid renders the removal of the former without the latter, or *vice versâ*, very difficult in this animal Under these circumstances we can remove both together and afterwards give thyroid extract to prevent the onset of symptoms from loss of thyroid secretion The symptoms which then occur, as I hope to show in my next lecture are nervous in origin and are due, I believe to the loss of the parathyroids. Opportunities of observing the effects of total thyroidectomy in man have occurred in cases in which that operation has

FIG 5



Thyroid gland and pituitary gland from a case of myxœdema

been performed for goitre It is well known that in a certain number of these cases as a result of the loss of the thyroidal secretion symptoms develop which are identical with those of primary myxœdema Indeed, it was the striking similarity between the two noticed by Sir F Semon which led to the appointment of the committee by the Clinical Society of London, whose report proved the identity of the two conditions and their dependence upon loss of function of the thyroid gland

THE CHANGES IN THE GLAND IN PRIMARY MYXŒDEMA

In man only three of the diseases which occur in the thyroid gland appear to be capable of causing a sufficiently

A slight swelling of the upper and lower eyelids appeared. In the fourth week there was marked inactivity, the characteristic attitude was adopted, and the tremors were well marked. There was distinct myxœdematous swelling of the eyelids and lips. The red corpuscles were diminished and the white increased in number. The temperature showed marked daily variations and was subnormal on three mornings. On the twenty-sixth day treatment was commenced by subcutaneous injection of thyroid extract and continued till the forty-fourth day, 20 minims in all being injected during this period. As a result of this treatment during the fifth week the tremors, swelling, and anæmia all diminished and there was more activity. The morning temperature still continued to fall and was only 95·4° on the twenty-second day. The following day the animal had an epileptic fit followed by an increase of the tremors and fibrillary muscular contractions and spastic rigidity of the flexors of the limbs lasting for some hours. After this the improvement steadily continued till at the end of the seventh week all the symptoms had disappeared and with the exception of a slight loss of weight the monkey was as well as before the operation. The treatment was discontinued and the symptoms returned again much in the same manner as they had at first. Treatment was again resumed but too late, as dysentery developed in addition to the myxœdematous symptoms and the animal died 13 weeks after the operation. Fig. 3 shows this animal after the return of the symptoms.

II. A male bonnet monkey. In this case the symptoms first began two days after thyroidectomy and were well marked by the fourteenth day when treatment was commenced by injections of a solution of the alcoholic precipitate of thyroid extract in glycerine and water. The symptoms had disappeared by the twenty-sixth day. The symptoms again returned and although improvement followed the use of thyroid extract death occurred after several severe convulsions on the sixty-ninth day.

III. In this experiment the symptoms commenced as early as the first day after thyroidectomy. Treatment was commenced on the fifth day by injections of a solution of a nucleo-albumin prepared from fresh thyroid glands by Halliburton's method in a 2 per cent. solution of sodium carbonate. There was some temporary improvement in the symptoms, but they returned in spite of continued treatment, and death took place on the twelfth day. This experiment, however, is of doubtful value, as Hutchison[31] has since maintained that a solution thus prepared would not contain the active secretion of the gland.

In these three experiments, though the actual presence of the parathyroid glands in the thyroid was not proved by microscopical examination, there can be little doubt that they were removed with it. In the two following experiments the animals were treated with thyroid extract for some time before as well as after the removal of the thyroid gland along with the parathyroids as ascertained by microscopical examination.

IV. A small male bonnet monkey was given one minim of thyroid extract by the mouth per diem for 44 days and then three minims daily for the next 31 days when the thyroid and the parathyroid glands were removed. The same dose of three minims was continued after the operation. No symptoms at all developed till the forty-second day after the operation. On this day it was noticed that on climbing down from the perch the monkey fell part of the way on to the floor of the cage and was unable to climb up again. It then showed general fibrillary twitching of the muscles in all parts of the body. The arms were rigid owing to spasm of the flexor muscles, which could be overcome without much difficulty but returned at once. The legs also were flexed at all the joints except the ankle-joints, which were extended, There was no subcutaneous swelling of the face or elsewhere. The rectal temperature was 100·6° F. A dose of six minims of liquor thyroidei was given but the animal became worse and died the same day.

V. A small male bonnet monkey was given one minim of thyroid extract by the mouth for 44 days, the daily dose was then increased to three minims for the next 42 days, when the thyroid gland was removed with the parathyroid glands. The dose of thyroid extract was continued as before. On the eleventh day after the operation there was some loss of activity and the lower eyelids were slightly swollen. After this there was progressive loss of strength and activity and the eyelids and lips became more swollen. Spastic rigidity of the limbs developed and on the nineteenth day after the operation the animal was found lying dead at the bottom of the cage. The swelling of the face was largely due to the presence of a fluid œdema which escaped when the skin was incised.

It is thus evident that although in some cases the symptoms which follow thyroidectomy in monkeys disappear when the loss is made good by giving thyroid extract, in others there is *only* an improvement and death afterwards results with acute nervous symptoms. Edmunds[32] has also found that under similar circumstances thyroid extract produces a marked benefit but does not save the life of the animal. From these facts and from the results of removal of the parathyroid glands in other animals it seems most probable that the acute nervous symptoms in the monkey such as the fibrillary twitchings, the spastic rigidity, and perhaps also the tremor and convulsions are largely due to loss of the parathyroids, while the subcutaneous swelling, dryness of skin, loss of hair, subnormal temperature, and changes in the blood are due to loss of the thyroid secretion. This conclusion receives further support from the close resemblance of the latter symptoms to those of primary myxœdema in man which we know to be the result of disease of the thyroid glands, there being no evidence as yet to show that the parathyroids are affected in this disease. If this be the correct explanation it is not surprising that these particular symptoms are not influenced by the thyroid extract.

TREATMENT OF MYXŒDEMA BY THYROID EXTRACT.

In primary and secondary myxœdema in man we see the results of loss of thyroid secretion pure and simple and consequently are able to remove the symptoms entirely by giving a sufficient supply of the secretion. Soon after I first determined to try this method of treatment in myxœdema I was fortunate enough to come across a well-marked case in a woman who, after the nature and experimental character of the treatment had been explained to her, was bold enough to give full permission for it to be carried out whatever the result might be. The patient having been shown at a meeting of the Northumberland and Durham Medical Society and the proposed treatment described it was commenced in April, 1891. The symptoms soon disappeared, proving the correctness of the conclusions which had led to the suggestion of the remedy. Nearly eight years have elapsed and this first case still remains free from myxœdema.

We may now briefly consider the method of carrying out this treatment of myxœdema. The main objects of the treatment are to remove the symptoms by restoring normal metabolism as rapidly as possible without risk to the patient, and when this has been accomplished so to regulate the treatment as to continue the supply of thyroid secretion in sufficient quantity to maintain the normal rate of metabolism of the tissues generally. For this purpose the treatment is divided into two stages. During the first stage the tissues are gradually brought back to a normal condition. This may, according to the severity of the symptoms, require from one to three months. As soon as the symptoms have entirely disappeared the first stage is completed. The condition of the atrophied thyroid gland is not influenced by the treatment so that if the artificial supply of secretion is discontinued at this or any other time of the patient's life all the symptoms of myxœdema will gradually return as I have found by actual experience. Thus the second stage of the treatment of necessity lasts as long as the patient lives. It is therefore necessary to make the permanent daily dose as nearly as possible equivalent to the normal amount of secretion. If the dose falls below this slight symptoms of myxœdema will reappear and if it is excessive a condition of thyroidism will be produced.

PREPARATIONS OF THYROID SECRETION.

Thyroid secretion can be given in several different forms. The actual gland itself containing the secretion may be used and is a useful form when the patient lives in some remote place or when it is necessary to make the treatment as inexpensive as possible. Arrangements can easily be made for the regular supply of one lobe of the thyroid gland of a freshly killed sheep twice a week by a butcher who has once been shown where the gland lies and the ease with which it may be removed. From one-eighth to one-quarter of a lobe is a suitable daily dose of the sheep's gland, one-quarter of a lobe being equivalent to about 10 minims of liquor thyroidei. As the raw gland is somewhat nauseous it should be minced and taken in glycerine or some similar vehicle in order to make it palatable or it may be lightly cooked on the outside by frying or boiling before it is eaten. As a rule, it is much better to employ one of the preparations of the thyroid gland rather than what may be termed the crude drug itself. Of these two are now official, liquor thyroidei and thyroideum siccum, the former of which is simply the original liquid thyroid extract. The liquor thyroidei is the most convenient preparation for general use and in my experience the most efficient. It is prepared from a considerable number of glands at a time, so that the strength is uniform. In prescribing it should be ordered in the undiluted form and not more than a sufficient supply for a fortnight should be obtained at one time. The patient must be provided with a minim measure glass and measure out the dose of five or 10 minims as the case may be, adding a dessertspoonful of water at the time it is taken. This preparation is conveniently given in a single daily dose at bedtime. The dry thyroid of the Pharmacopœia may be given as a powder or made up into a pill or tablet. If the dried preparation becomes damp at all it is liable to decompose and become unfit for use.

[31] Journal of Physiology, vol. xx., 1896.

[32] Proceedings of the Royal Society, vol. lxiv.

METHOD OF TREATMENT.

In advanced cases the first stage of the treatment must be carried out with great caution, especially if any symptoms of degeneration of the cardiac muscle, such as attacks of syncope, dyspnœa on exertion, feeble or irregular pulse, or weak heart sounds are present. Under these circumstances the patient should be confined to bed at first and only small doses of from three to five minims of liquor thyroidei given each night. This dose if well borne may be gradually increased up to 10 minims. If not confined to bed these patients are apt to make use of their returning vigour too soon, before the heart has had time to recover and to adapt itself to the altered conditions brought about by the treatment. These advanced cases in which little exercise has been taken for months or even years are now rare, but in the early days of the treatment the importance of this caution was painfully impressed upon me by the deaths of two patients from syncope who had cardiac disease, after they had practically got rid of the symptoms of myxœdema. Any undue acceleration of the pulse up to 90 or 100 indicates that a reduction should be made in the dose and any signs of cardiac failure must be met by giving stimulants and digitalis. By far the greater number of cases which require treatment are now seen in the early stages of the disease before any cardiac symptoms have developed. In these the patient is able to go about as usual, though it is advisable to avoid any unusual exertion during the first stage of the treatment. A daily dose of 10 minims of thyroid extract may be given each night from the beginning and increased to 15 minims at the end of a fortnight if decided improvement has not already taken place. Any marked increase in the frequency of the pulse or rapid loss of weight is an indication for at once reducing the dose. Symptoms of gastro-intestinal catarrh have sometimes arisen during this first stage of the treatment especially if the raw gland has been used. They rarely if ever appear if a suitable preparation of the gland is used instead. If they do occur the thyroid treatment should be stopped until they have passed away and then smaller doses should be given when the treatment is again commenced. In many cases no other treatment beyond the daily dose of thyroid extract is required. When, however, there is a well-marked anæmia it is a good plan to give iron as well as thyroid extract. Five grains of dried sulphate of iron in a pill twice or thrice daily after meals is a suitable form in which to give it.

As soon as all the symptoms of myxœdema have disappeared the first stage of the treatment is completed. The second stage then commences and must of necessity last as long as the patient lives. During this stage the patient must continue steadily to take a daily dose of thyroid extract equivalent to the daily output of the gland before it became diseased or at any rate of that part of it which has become functionless. It is important that patients should understand this and that good health can only be maintained by the continued use of the remedy. To ensure this it is often better to describe the remedy as an essential part of the daily diet and not as a medicine so as to overcome the objection some persons have to taking what they regard as a medicine for such long periods. Of course, an occasional intermission of the treatment for a week or so has little or no effect, but if no thyroid extract is taken for three or four weeks the temperature falls one or two degrees below normal and the myxœdematous swelling of the face begins to develop again. If the extract is omitted for a longer period still all the original symptoms gradually reappear till at the end of three or four months the condition will be much the same as it was before any treatment was adopted. The most suitable dose for the second stage of the treatment is, generally speaking, 10 minims of the extract given once a day. If after a time any slight symptoms of myxœdema reappear the permanent dose should be increased to 12 or 15 minims. In none of my own cases has it been necessary to give more than 10 minims; in a few cases this dose is too large, as after a time it produces acceleration of the pulse. The permanent dose has then to be fixed at five or seven minims a day. In doubtful cases of myxœdema thyroid extract may be given as a means of diagnosis. For this purpose a dose of 10 minims should be given daily for three or four weeks. If the symptoms steadily diminish they are the result of thyroidal disease; if, on the other hand, no improvement takes place they are due to some other cause. This test is of great use in distinguishing some of the cases with anæmia and subcutaneous swelling from cases of anæmia with ordinary obesity which they often closely resemble.

RESULTS OF THE TREATMENT OF MYXŒDEMA.

When the treatment of a well-marked case of myxœdema is carried out on the lines just indicated very definite and interesting results are soon obtained. One of the earliest signs of improvement is in the return of the temperature to the normal level. This is illustrated by one case in which the temperature before treatment ranged from 95° to 96° F., whereas during the second, third, and fourth weeks of treatment it varied between 96° and 98°. As the temperature rises to normal the former sensitiveness to cold is lost and the frequency of the pulse is increased. The most striking changes are those which take place in the skin with its appendages and in the subcutaneous tissues. The myxœdematous swelling gradually disappears from all parts of the body so that the face and hands once more assume their natural appearance and the free movement of the limbs which has been considerably hampered by the swelling is regained. The reduction of the swelling is accompanied by a loss of weight which may amount to as much as two or even four stones. The skin, which as a result of the removal of the swelling may for a time remain loose and wrinkled, becomes warm and moist owing to a renewal of the secretory activity of the sebaceous and sweat glands. Not infrequently there is some desquamation which may occur in fine scales or in large flakes from the palms of the hands and soles of the feet, as observed by Byrom Bramwell.[33] The hair follicles resume their proper function, so that even where there has been complete baldness a good growth of hair is developed in the course of six or 12 months. Considerable changes are thus produced in the appearance of the patient and they are well illustrated by the four photographs shown in Figs. 8, 9, 10, and 11. They both illustrate the changes which take place in the appearance of the patient *pari passu* with the advance of the local disease of the thyroid gland and the result of treatment. This case was kindly placed under my care by Mr. James Angus of Newcastle-on-Tyne, and although I have published Figs. 8 and 9 before I venture to reproduce them along with two earlier photographs of the same case for which I am indebted to my colleague Dr. Thomas Oliver. Fig. 8 was taken in 1883, four years after the symptoms first appeared in 1879. Fig. 9 was taken in 1890, showing a more advanced stage of the disease, and Fig. 10 in 1891 just before the treatment was commenced when the disease had already existed for 12 years. Fig. 11 was taken in 1892 after treatment for seven months and shows that the swelling has disappeared and a good growth of hair has taken place. As already mentioned, this patient died from mitral disease in 1897 when the thyroid gland was found to be entirely converted into fibrous tissue and fat as was shown in Fig. 7.

In addition to these very obvious signs of improvement the feeling of lassitude passes away and normal muscular strength and activity are regained. As a result of this those who before treatment could barely walk a mile are enabled to walk long distances, climb mountains, and undertake various other forms of exercise, mental processes become more active, the memory improves, and the hallucinations disappear. In some cases in which actual insanity had occurred it also has been cured. If albuminuria without actual renal disease has been present it disappears while the amount of urine is increased. The observations of Ord and White[34] show that the total amount of nitrogen eliminated is increased and that this increase is almost entirely due to the increase of urea in the urine. At first the amount of urea excreted may not only equal, but actually exceed, the normal average quantity. The number of red corpuscles in the blood increases. In patients who have not reached the menopause menstruation returns and takes place regularly even when there has been amenorrhœa for several years. In fact, the myxœdema is entirely cured though the fibrosis of the thyroid gland remains unaffected by the treatment.

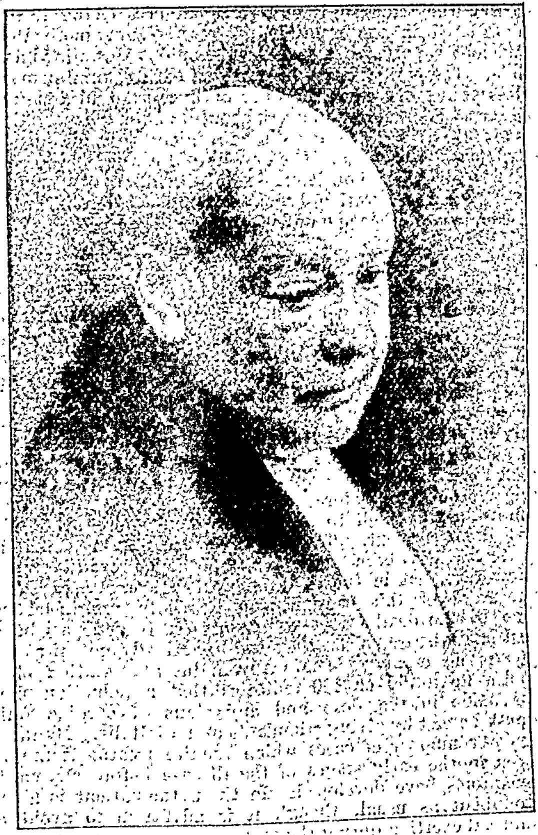
Eleven years after the onset of the disease.

TREATMENT OF CRETINISM.

We have already considered the results of athyroidism in young animals and children and have seen how they are more serious than in the adult owing to the arrest of development. The treatment of a cretin consequently presents a more formidable task, but the results are in some respects even more interesting than those just described. I would again point out the importance of carefully considering the possibility of the presence of disease or lack of development of the thyroid gland in every case of arrest or delay of development in children. In all such cases it is important to look for slight signs of cretinism. There are of course other causes of arrest of growth, such as achondroplasia, but I have seen several cases where the ordinary symptoms of cretinism were not distinct and might easily escape observation if not searched for carefully, in which the rapid improvement following thyroid treatment has proved that the arrest of development was due to thyroidal insufficiency. The importance of early diagnosis in such cases lies in the fact that the earlier the treatment is commenced the better prospect there is of normal development of the central nervous system. Experience has already shown that in cretinism of some years' duration rapid as the improvement in the physical condition may be the intellectual development is much slower, so that when treatment is commenced late it is doubtful if the latter will ever advance as far as when treatment is started early. If any doubt exists as to the diagnosis it is a good plan to carry out the treatment for one or two months. If no distinct improvement takes place the want of development is not due to cretinism, for in other forms of arrested growth the treatment has comparatively little effect though it is worthy of trial. The treatment of early cretinism is carried out on

FIG. 10.



At commencement of treatment when the disease had lasted for 12 years.

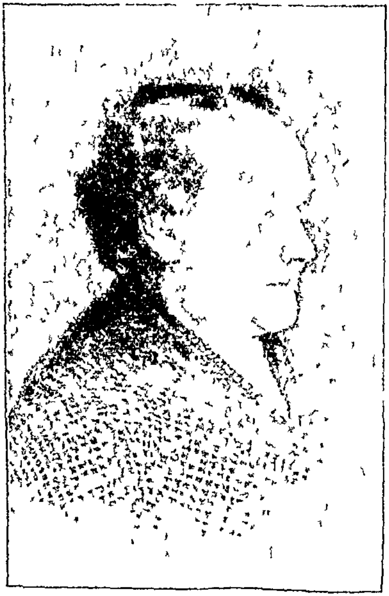
---

[34] Brit. Med. Jour., July 29th, 1893, p. 217.

the same lines as the treatment of myxœdema in the adult. During the first stage gradually increasing doses of thyroid extract are given till the symptoms disappear. It is advisable in treating a small cretin to begin with a dose of one or two minims each evening, gradually increased by the addition of one minim each week or fortnight until a dose of five, seven, or 10 minims, according to the size of the child, is reached. As the child gets older it may be found necessary to increase the daily dose from time to time by the addition of another minim. If too large doses are given the pulse becomes too frequent, pains may be felt in the limbs and elsewhere, the temperature may rise above the normal level, and purging may follow. As in the adult the treatment must be continued as long as the patient lives. As soon as the symptoms have disappeared it is only necessary to determine the most suitable permanent dose and to ensure its uninterrupted administration.

In the treatment of cretinism which has lasted for some years we have a much more difficult task to perform, but very good results can be obtained. Even when the disease has already lasted 10 or 12 years, provided the patient is not more than 18 or 20 years old, a remarkable amount of growth can still take place. In these cases from three to five minims of thyroid extract may be given at the commencement and increased according to the progress observed. Even in cases in which the symptoms have lasted for 20 or 25 years some growth and marked improvement in all the symptoms take place. In cases of long duration attacks of syncope are not uncommon. In such the earlier part of the treatment is more safely accomplished by keeping the patient in bed and giving small doses of one or two minims only at first.

FIG 11

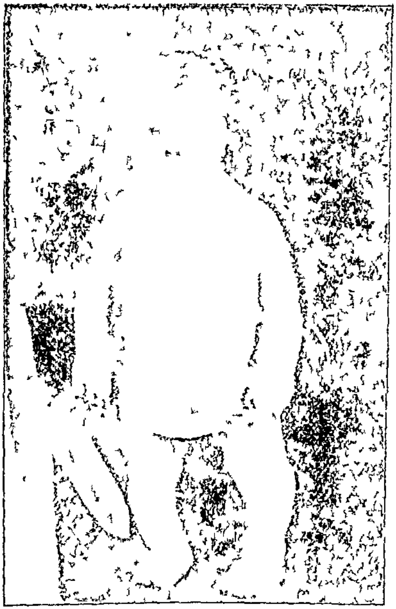


After treatment for seven months

Results of the Treatment of Cretinism

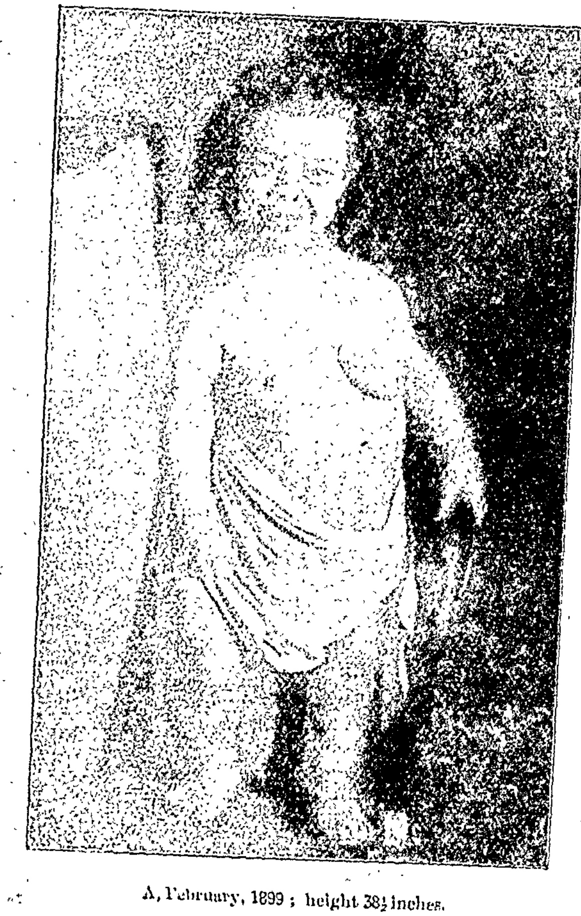
When the necessary stimulus to the normal metabolism of growth is thus supplied to a cretin in the early stages of the disease the symptoms disappear. The swelling gradually diminishes in all parts of the body. The tongue, lips, and nose diminish in size so that the appearance becomes natural. The skin becomes soft and moist and the temperature rises to normal. Growth which at this early stage will only have been partially arrested starts afresh. If the treatment is continuously carried on in such a case from the earliest time at which the disease is recognisable there seems no reason to doubt that ultimately the child will grow up into a fully developed healthy adult who, however, would of course at any time develop symptoms of myxœdema if his supply of the extract was discontinued. The amount of improvement which may take place in very advanced cases is well illustrated by the further course of the case (A) described and shown in Fig 12. In this case the symptoms had been present for some 27 years before treatment was commenced. The dose was at first one drop a day, and has been gradually increased till now she takes 15 drops, equal to about 12 minims of thyroid extract daily. At the commencement of the treatment growth had been arrested, apparently for many years, as she only measured 34½ inches in height. She now measures 38½ inches, having grown four inches in three and a half years. The hair is much less coarse than it used to be and the scalp is white and smooth. The swelling has greatly diminished so that the nose, cheeks, and lips are much smaller than they were and the whole expression is much more bright and intelligent. The mouth is kept closed and the tongue has become normal in size and no longer protrudes between the lips. The condition of the teeth does not seem to have improved except that she can now crack nuts which she was unable to do before. The elastic pads have disappeared from the supra clavicular regions. A most remarkable development of the mammary glands, which before treatment were [illegible]loped, has [illegible] place. This is [illegible] pl[illegible] (Fig 13) in [illegible]

FIG 12



A, age 23 years June 1895 height 34½ inches breasts are now very well developed. Some pubic hairs have grown and menstruation which had only occurred very scantily on a few occasions is now regular and abundant. The abdomen is less prominent and the umbilicus is retracted. There is still marked lordosis. The *skin is much less dry* and perspires freely when she is walking. She is much more energetic and the muscular strength has increased so that she can now walk two miles. The temperature has long been normal. She is distinctly more intelligent, her vocabulary has increased, she can recognise people and animals, and can make her wants perfectly understood. She is unable, however, to frame a sentence and uses only single words, or at most two or three together. She is careful and cleanly in her habits.

FIG. 13.



A, February, 1899; height 38½ inches.

This case is a good example of the amount of improvement of which even the worst cases are capable. Greater improvement still has been *obtained in cases* of some years' duration in which the patients are still under 20 years of age. Thus in Dr. John Thomson's[35] patient, aged 18 years and eight months, 33½ inches in height, there was an increase in the height of four and three-eighth inches in 12 months; and in Dr. Byrom Bramwell's[36] patient, aged 16 years and four months, 29½ inches high, growth was at the rate of six and a half inches in six months.

The intellectual development is always much slower than the bodily growth and general improvement in all other respects. *The shorter the duration of the symptoms has been* at the commencement of the treatment the more rapid the improvement in the mental condition and I think it is only in cases in which the treatment is started early that we can expect normal intellectual development to take place. In cases of some duration it is important that a special education should be carried on at the same time as the treatment in order that the patient may be able to make the most of the renewed cerebral activity.

The Milroy Lectures

ON

THE EARTH IN RELATION TO THE PRESERVATION AND DESTRUCTION OF CONTAGIA.

Delivered at the Royal College of Physicians of London on Feb. 23rd and 28th and March 2nd, 1899,

BY G. V. POORE, M.D., F.R.C.P. LOND.,
PROFESSOR OF MEDICAL JURISPRUDENCE AND CLINICAL MEDICINE, UNIVERSITY COLLEGE; PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

LECTURE III.[1]

Delivered on March 2nd, 1899.

AGRICULTURE.

MR. PRESIDENT AND GENTLEMEN,—The facts with which we have been dealing in these lectures show:—1. That there are certain organisms which are indigenous to the soil and ubiquitous. These organisms, if they contaminate a surgical wound or are inoculated, may cause septicæmia, erysipelas, malignant œdema, or tetanus. They are very *possibly* necessary saprophytes, and we recognise that it is useless to attempt to "stamp out" the germs of these surgical contagia, although (thanks to Lord Lister) the surgeon is able to protect his patient from the evils which arise from them and to prevent their cultivation in hospitals. Apart from accidental inoculation these organisms are not dangerous. We must often swallow them with our food and drink and inhale them with our breath and no practical harm results. These contagia are persistent in the soil and are probably most common in soils which are richest in organic matter. 2. The contagium of anthrax is apparently difficult to eradicate from a soil which has once been contaminated with it. This is probably due to the fact of sporulation and to the spore being very resistant to external influences of all kinds. The evidence, such as it is, points to the fact that in temperate countries at *least* the contagium dies out *of the soil in time.* M. Pasteur's experiments were vitiated by the circumstance that they were made in districts where the *disease* was and had been rife. More information is needed as to how far the infection of animals depends upon wounds of the skin or mucous membrane and on the vulnerability of the animals by the mal-hygienic conditions in which they live. It is possible that in tropical countries the bacillus anthracis is indigenous to the soil. Man apparently does not acquire anthrax by inhaling or swallowing pulverised earth. He is always infected through the medium of infected animals or their skins, flesh, or wool. 3. To what extent malaria is directly a soil disease, apart from the mosquito as a connecting link, is in the present state of our knowledge doubtful. There is no doubt, however, that malaria disappears before drainage and cultivation. 4. With regard to enteric fever, diarrhœa, plague, and some other diseases there can be no doubt that they are all favoured by filth although we are ignorant of the precise way in which filth favours the occurrence of these diseases. Some might say that a filth disease is a soil disease and that there is no line of demarcation between the two. This is true, but it is nevertheless very necessary for practical purposes to distinguish the one from the other. We are all agreed that it is dangerous to allow the purlieus of a house to become sodden with liquid filth, but it might be equally dangerous to the public health to encourage the idea that it is dangerous to dung the land for fear of inoculating it with infectious disease. Happily, from the laboratories we get comfort in this matter. Sidney Martin has shown (as Dempster had previously shown with regard to peat) that "virgin soil," whether sandy or peaty, is, even when sterilised, fatal to the bacillus typhosus, and one naturally asks, What is virginity? and whether cultivated soils by excessive production do not tend, paradoxical as the question may sound, to return to that condition of virginity in which they are able to grapple with infective organisms? The evidence goes to show that cultivation and production are the enemies of dung infections. Robertson and Gibson found that a growth of grass was fatal to the bacillus typhosus. That dung contagia must be destroyed or their virulence be diminished by tillage is self-evident. Were it otherwise our race must long since have been extinguished. The race which has shown the greatest persistence in this world (the Chinese) is precisely that one which has systematically inoculated its native soil with dung contagia for three or four millennia. Politically they are said to be sick but physically and economically they are "going strong" and are likely to continue. 5. The fact that most of the alleged soil diseases are more rife in the crowded centres of population than in the rural districts is a fact which must not be lost sight of. Whether this be due to the greater vulnerability of town populations or to the soakage of the purlieus of the house from leaking sewers it is difficult to say. In any case it is incontestable that soil diseases (so-called) are most rife precisely in those spots where the ground is not cultivated.

---

[35] Edinburgh Medical Journal, February, 1844.
[36] Brit. Med. Jour., Jan. 6th, 1894.

[1] Lectures I. and II. were published in THE LANCET of Feb. 25th and March 4th, 1899, respectively.

Infective organisms contained in dung have to run the gauntlet of many enemies, such as dogs, sparrows, rats, flies, maggots, beetles, earthworms, moles, sunlight, fresh air, innumerable saprophytes (both aerobic and anaerobic), and the chemical action of the roots of plants. Of course, there may be spores which emerge from these ordeals unharmed and still virulent, but it is evident that, being mortal as we are, they are likely to succumb before the digestive and disintegrating processes which they encounter. The bulk of the evidence goes to show that contagia must be largely destroyed in the soil and that agriculture is really the cornerstone of preventive medicine. It becomes of great importance, therefore, to devise means by which the fertilising material of our towns may be applied to the soil with safety and despatch.

I may be pardoned for reverting to the method of dealing with human excreta which I have practised now for 12 years in my experimental garden at Andover: (1) the excreta are moved every day so that there is no accumulation of filth near the dwelling; (2) they are put just below the surface of freshly-dug ground so that they are out of the reach of flies; and (3) the ground is planted with plants of the cabbage order as quickly as may be so that very soon there is no possibility of dust being blown off the surface of the ground, and the mass of living cabbage leaves freshens the air. I cannot believe that dust from agricultural land is a danger in this country whatever it may be in the tropics. In my garden the ground treated in the manner stated, apart from the growth of cabbages, soon becomes coated with a green growth of alga. Mr. A. Gepp of the Natural History Museum who visited my garden last summer took some of this growth away and very kindly examined it and he pronounced it to be an alga—"chiefly vaucheria sessilis (in good fruiting state) with a little ulothrix, a glœocystis, and an oscillatoria." Such a growth effectually prevents the possibility of dust.

Dr. Samuel Hyde[2] speaking on the Open-Air Treatment of Consumption says: "Sparseness of vegetation, like thinness of population, is a climatic factor favourable to the treatment of consumption. Where vegetable life abounds there vegetable decomposition must also abound and *vice versâ.* Wherever there is life we have a corresponding amount of death accompanied necessarily by the products of decomposition." This is quite true and our experience teaches us that, provided the supply of food be adequate, a high level of health may be maintained in places where there is little or no vegetation, as upon the sea and on alpine heights and in arctic solitudes. "Wherever there is life," says Dr. Hyde, "we have a corresponding amount of death." That is true, but the converse is also true and we may say that wherever there is death we have the potentiality of a corresponding amount of life. I believe that what I have called the circulation of organic matter is a beneficent fact from which there is no escape and that whether we derive good or ill from the inevitable processes of death and decay depends very much upon ourselves. We must never forget that vegetation purifies the soil, freshens the air, rests the eye, and prevents dust, and these facts must be recognised as to a great extent counterbalancing the evils of dead leaves.

There are always *pros* and *cons* which have to be weighed. Nothing makes entirely for good or entirely for evil and we have always to balance our accounts and to see whether the general effect be good or ill. The British sanitarian is so circumstanced that he need not trouble himself at all about the most important of all sanitary considerations—viz., food-supply. He is busy in burning or washing into the sea every kind of fertilising matter, and if a general coal strike or a war were to suddenly bring famine with its attendant diseases to our doors he would protest that that was no concern of his. With our steadily diminishing birth-rate and the daily increase of institutions for the reception of those whose moral, mental, or physical diseases prevent them from earning their own living it is difficult to believe that the stamina of our highly civilised urban populations is increasing. Apart from the question of food-supply, it is, I believe, absolutely necessary to encourage agriculture in order that our race may be maintained in vigour. The strong contrast which exists between the agriculturist and the town worker in the matter of health is well known.

Dr. Tatham's letter to the Registrar-General on the mortality of males engaged in certain occupations in the three years 1890-92, which constitutes Part II. of the Supplement to the Fifty-fifth Annual Report to the Registrar-General, shows clearly enough that the agricultural classes in this country enjoy a large measure of health. Dr. Tatham's statistics refer to occupied males between the ages of 25 and 65 years and the tendency to disease and death is indicated by a mortality figure, the mortality for all males between 45 and 65 years of age being taken as 100. The following table taken from p. 18 of this report shows the mortality of three great classes of the community with perfect clearness.

Table (deduced from Table IV.) showing the mortality from certain specified causes in each of three sections of occupied males, as compared with that among all occupied males, the mortality of the latter being taken as 100 in each case.

—	All occupied males.	Occupied males, London.	Occupied males, industrial districts.	Occupied males, agricultural districts.
All causes	100	120	131	72
Influenza	100	100	100	100
Alcoholism	100	138	146	54
Rheumatic fever	100	100	114	86
Gout	100	300	100	100
Cancer	100	134	109	91
Phthisis	100	150	121	73
Diabetes	100	114	100	100
Diseases of the nervous system	100	107	132	77
Diseases of the circulatory system	100	107	122	75
Diseases of the respiratory system	100	124	166	61
Diseases of the liver...	100	111	119	89
Other diseases of the digestive system	100	100	129	82
Diseases of the urinary system	100	137	122	73
Accident	100	86	105	79
Suicide	100	129	114	88
Other causes	100	91	130	76

The following table which is deduced from Table IV. shows the mortality from certain specified causes in the agricultural class as a whole and in its several divisions as compared with the standard mortality among all occupied males, the latter being taken as 100.

---

[2] Brit. Med Jour., Oct. 8th, 1898.

—	All occupied males.	Occupied males in agricultural districts.	Agricultural class.	Agriculturists in agricultural districts.	Farmer, grazier, &c.	Farmer, grazier, &c., in agricultural districts.	Farm labourer.	Labourer in agricultural districts.	Gardener, nurseryman.
All causes	100	72	63	64	59	53	66	70	58
Influenza	100	100	109	112	115	112	112	118	82
Alcoholism	100	54	31	31	46	31	31	31	31
Rheumatic fever	100	86	86	71	86	71	71	57	100
Gout...	100	100	50	50	50	100	50	50	50

Phthisis	100	73	57	63	43	44	62	70	61
Diabetes	100	100	86	86	143	157	71	71	57
Diseases of nervous system...	100	77	62	63	62	50	65	71	57
Diseases of circulatory system	100	75	66	68	61	52	71	75	61
Diseases of respiratory system	100	51	52	49	41	29	58	57	48
Diseases of the liver	100	89	63	59	96	81	48	56	63
Other diseases of digestive system	100	82	82	75	96	75	79	75	64
Diseases of urinary system	100	78	59	59	71	68	51	56	63
Accident	100	79	63	68	53	54	74	77	39
Suicide	100	86	71	71	100	129	57	50	71
All other causes	100	76	73	76	65	61	79	86	61

Out of the 16 causes specified in this table, there is only one in which the mortality of agriculturists as a class exceeds that of occupied males generally. The exception is influenza, the mortality from which disease shows an excess equal to 9 per cent. The chief excess under this heading probably occurred in the first quarter of the year 1892, which was marked by a severe outbreak of influenza specially affecting the country districts. The mortality among agriculturists from phthisis does not exceed 57 per cent., and that from diseases of the respiratory system does not exceed 52 per cent. of the standard mortality among occupied males, and their mortality from all other diseases of the local class is considerably below the same standard.

These tables show conclusively that agriculturists are among the healthiest class in the community and that even the farm labourer in the matter of health is 33 per cent. better than the average. This is a matter of great interest and importance. He is often represented as half starved, miserably housed, a martyr to rheumatism, and poisoned by filthy water. As a matter of fact as regards sobriety and health he might be taken as a model by the rest of the industrial classes. There is another point of view from which agriculture is of great importance. We are beginning to find out that a factory hand who has to keep pace with steam machinery becomes "too old for his work" at a comparatively early age. Defects of eyesight or hearing or a lessening of acuteness and nimbleness soon unfit a man for employments where dexterity is of more importance than experience. There has been much talk of late of "old age pensions," but it must be admitted that even if the financial difficulties of the question could be overcome the prospect of being *without employment* and existing on a pittance without any true interest in life after the age of 55 years is not cheerful. I believe that the practice of agriculture is [illegible] only remedy for this and that the best old age [illegible] will be found in the possession of an acre or [illegible]d. Not only are the ordinary horticultural [illegible] possible for a man long after he is capable [illegible] machinery but such a possession would [illegible]tual in life and he would find that the pro[illegible]th and would certainly increase with time [illegible] the amount of skill and labour [illegible]ltivation and the quantity of [illegible] soil.

[illegible] mental [illegible] treatment [illegible]try at the present day. I [illegible]ctual develop[illegible]ilities for the transfer of [illegible]pear to show that the [illegible] essential, apart from the [illegible]nance of the vigour of our race. Anything which discourages or increases the difficulties of agriculturists can hardly be in the interests of the public health.

THE MAINTENANCE OF THE FERTILITY OF THE SOIL.

There is much evidence to show that dung is absolutely necessary to maintain the fertility of the soil. In a paper by Sir John Lawes and Sir Henry Gilbert on the valuation of unexhausted manures[3] the difference between organic manures and mineral manures is well brought out. The lasting effects produced by farmyard manure (14 tons to the acre) are shown in the annexed table.

TABLE I.—*Experiments with Farmyard Manure on Permanent Grass Land.*

—		Unmanured every year.	Manured 1856–63; unmanured since.	Excess of manured over unmanured.
		cwt.	cwt.	cwt.
8 years 1856–63	1st crops only	23¾	42⅞	19⅛
12 years 1864–75		19⅝	32⅞	13¼
20 years 1876–95 (1st and 2nd crops)		25⅞	29⅞	4

In only one year—1893, a year of drought—did the manured plot give less produce than the unmanured. The authors say: "It is true that the application of 14 tons of farmyard manure per acre per annum for eight years in succession is an unusually heavy dressing; but it is of interest to know that the residue was very materially effective for some years, and that it was more or less so for THIRTY-TWO YEARS after the application" (the capital letters are my own). The following table giving experiments with barley tells the same tale.

TABLE II.—*Experiments with Barley 1852–96.*

—	Unmanured every year.	Mixed minerals every year (no nitrogen).	Farmyard manure.	
			Every year.	20 years 1852–71; unmanured since.
	Bushels.	Bushels.	Bushels.	Bushels.
20 years 1852–71 ...	20	27½	48¼	48¼
25 years 1872–96 ...	12⅞	16⅞	49¼	29

The above table shows that the effect of the farmyard manure is very appreciable for at least a quarter of a century. It also shows that when farmyard manure was used every year the yield for the final 25 years was greater than in the first 20 years. It also shows that the increase by using mineral manures without nitrogen is appreciable but slight. The use of rape-cake as an organic manure for barley gave interesting results which are set forth in Table III.

TABLE III.—*Rape-cake as a Manure for Barley 1852–91.*

—	Rape-cake alone.	Rape-cake with mixed mineral manures and nitrate *of soda.*
	Bushels per acre.	Bushels per acre.
20 years 1852–71 ...	45¼	49¾
" " 1872–91 ...	37⅛	41¼

It is to be noticed that the reduction in produce in the second 20 years as compared with the first amounted to more than eight bushels per acre. The reduction in the second 20 years was, in the opinion of the authors, mainly due to less favourable seasons, but nevertheless it is shown that

---

[illegible] Medical Journ[illegible]

[illegible] Med. Jour., [illegible]

[3] Journal of the Royal Agricultural Society, vol. viii., 1897, p. 674.

the yield with farmyard manure for the 25 years 1872-96 was 49 bushels as against 46¼ for the 20 years 1852-71. The experiments made in growing clover on rich garden soil are of great interest. This has been done for 40 years in a part of the Rothamsted kitchen garden which has been in cultivation for two or three centuries. The average yield for the 40 years was 59¼ cwt. or nearly three tons of hay which "would be a very good yield for the crop grown only occasionally in the ordinary course of agriculture." The average yield in the first 10 years was much greater than in the subsequent 30 years and averaged 95¼ cwt. and the maximum yield appears to have been about 148 cwt., or nearly seven and a half tons to the acre. In 1857, after the removal of the crops of the fourth year of the experiment, the surface soil nine inches deep contained four times as much nitrogen as the average of the Rothamsted arable soils to the same depth and nearly five times as much as the exhausted arable land where red clover had failed. The experiments on wheat with artificial manures are equally instructive.

TABLE IV.—*Showing the Yield of Wheat in Bushels per Acre*

Period.	Mixed mineral manure— Alone.	And NH₃ 86 lb. N.	And NH₃ 129 lb. N.	And NH₃ 172 lb. N for first 13 years (1852-64), *unmanured for last 19 years.*
	Plot 5	Plot 7	Plot 8	Plot 16
13 years 1852-64	18¾	37¼	33	39¼
19 years 1865-83	13¼	29¾	34¾	14¾

In the above experiments we find, no dung being used, that the yield is less in the second period than in the first, and that when the large amounts of artificial manure were withdrawn in Plot 16 the yield dropped almost at once. The authors say: "There is, in fact, abundant evidence to show that there is but little effective manure residue after the growth of a grain crop by the application of ammonium salts; and there is little doubt that the produce of one and a half bushels of grain and its straw per acre per annum more over the 19 years after the cessation of the application of ammonium salts than on Plot 5 with the mineral manure alone is, so far as it is to be attributed to residue, mainly due to the increased *crop residue*—stubble and roots accumulated during the 13 years of the application; and much the same may be said of the after-effects when grain crops have been grown with nitrate of soda." Again: "When organic matter, animal or vegetable, is applied to the soil as manure its complete decay and the complete liberation of its fertilising constituents extend over a considerable period of time. Poor land cannot be suddenly brought into *condition* by the consumption on the farm of purchased foods. Nor can condition—that is, accumulated fertility—be at once withdrawn by suddenly stopping the use of foods."

Food-supply.—Sir William Crookes, the President of the British Association, in his address (Bristol, 1898) drew attention to the fact that if population continued to increase we might expect to be short of wheat. Our remedy was to increase the fertility of the wheat-growing area of the world and, taking, as was perhaps but natural, a purely chemical view of fertility, he put forward the proposition that the productiveness of the soil might be expected to bear a direct ratio to the amount of fixed nitrogen which is applied to it and he found comfort in the fact that after the exhaustion of the nitre beds of Chili and the guano beds of Peru the chemist of the future would be able by the aid of electricity generated by Niagara and other natural forces to fix the atmospheric nitrogen for the benefit of the farmer. In the course of his address Sir William Crookes made allusion to the sewage question in the following words:

> "There is still another and invaluable source of fixed nitrogen. I mean the treasure locked up in the sewage and drainage of our towns. Individually the amount so lost is trifling, but multiply the loss by the number of inhabitants and we have the startling fact that in the United Kingdom we are content to hurry down our drains and watercourses into the sea fixed nitrogen to the amount of no less than £16,000,000 per annum. This unspeakable waste continues and no effective and universal method is yet contrived of converting sewage into corn. Of this barbaric waste of manurial constituents Liebig nearly half a century ago wrote in these prophetic words: 'Nothing will more certainly consummate the ruin of England than a scarcity of fertilisers—it means a scarcity of food. It is impossible that such a sinful violation of the divine laws of nature should for ever remain unpunished, and the time will probably come for England sooner than for any other country when, with all her wealth in gold, iron, and coal, she will be unable to buy one thousandth part of the food which she has during hundreds of years thrown recklessly away.' The more widely this wasteful system is extended, recklessly returning to the sea what we have taken from the land, the more surely and quickly will the finite stocks of nitrogen locked up in the soils of the world become exhausted. Let us remember that the plant creates nothing; there is nothing in bread which is not absorbed from the soil, and unless the abstracted nitrogen is returned to the soil its fertility must ultimately be exhausted."

Sir John Lawes and Sir Henry Gilbert in a communication addressed to the *Times* on Dec. 2nd, 1898, point out that even supposing that atmospheric nitrogen could be fixed at a remunerative price, the addition of nitrates without the addition of the other mineral constituents necessary for wheat growing would be of no permanent use; but they express the opinion that the stores of nitrogen and other fertilising salts existing in our own soils and the soils of foreign countries can be made available by thorough tillage and proper rotation of crops. The land wants labour and the production of wheat is likely to be proportionate to its market value. They point out that the average wheat production of the *unmanured* plot at Rothamsted (over 13 bushels) is greater than the average of the whole of the United States, a fact mainly due to proper tillage and thorough weeding.

It is tolerably evident that fertility is not merely a chemical question. The year 1898 was remarkable for a fine wheat crop in this country. The yield is said to have averaged 35 bushels instead of 28 or 29 bushels per acre. Sir John Lawes, in his annual letter to the *Times* (Oct. 22nd, 1898) on "The Wheat Crop of 1898" states that at Rothamsted the yield on the experimental plots was as under:—

TABLE V.—*Wheat Crop in 1898.*

—	Bushels per acre.	Cwts. of straw.
Plot 3, unmanured	12	12¼
Plot 9, nitrates	23¼	33¾
Plot 7, ammonia salts	28¾	44¾
„ 8, „ „	29¾	54¾
Plot 2, farmyard manure	38	65¾

In 1898 at Rothamsted the plot dressed with nitrate of soda yielded 23 bushels, as against 38 bushels on the farmyard plot, and in explanation Sir John Lawes says: "For only the second time during a period of more than 40 years the wheat plant was much injured where we have used the heaviest dressing of nitrate of soda for want of enough rain to form and distribute a sufficiently dilute solution of it; and a similar result occurred in the year of drought of 1893; whilst in this year, 1898, the barley plant was much injured with only half the amount of nitrate applied." Sir John Lawes also gives the average yield of these five plots for periods extending over 46 years.

TABLE VI.—*Wheat Crop, 1852-97.*

—	Unmanured.	Farmyard.	Ammonia salt.	Ammonia salt.	Nitrate of soda.
36 years 1852-87	13	33¼	32¾	36½	35¾
10 years 1888-97	12¼	40¾	34¼	37¼	33¾
46 years 1852-97	12⅝	35¼	33⅛	36¾	36⅛

From the above table it will be observed that not only has farmyard manure proved to be practically the equal of artificial manures for nearly half a century but that during the last ten years the yield from it has been considerably more than that of any of the artificially manured plots. It is interesting to observe, also, that had the wheat-growing area of this country in the year 1898 been sprinkled with nitrate of soda after the manner of Plot 9 at Rothamsted the yield might have averaged only 23 bushels instead of 35 bushels. On 2,000,000 acres, which is approximately the wheat area of the United Kingdom for 1898, this means a deficit of 24,000,000 bushels or 3,000,000 quarters. The chemical analysis of a soil often fails to give the clue to its fertility or sterility. Mr. Robert Elliot, in a paper on

"The Value of Plant-roots as Tillers of the Soil,"[4] quotes Sir John Lawes to the effect that "All our experiments tend to show that it is the physical condition of the soil, its capacity for absorbing and retaining water, its permeability to roots and its capacity for absorbing and radiating heat, that is of more importance than its, strictly speaking, chemical composition." It is, in fact, abundantly evident that the biological side of fertility is quite as important as the chemical and that organic manures are absolutely necessary to maintain the fertility of the soil, and that of all organic manure there is nothing to be compared with dung. If all that comes from the land be returned to it there can be no reason why the agriculturist should trouble himself with chemical theories. He has only by labour to maintain the soil in a good physical condition and he may rest assured that its fertility will increase.

SANITATION IN HOLLAND.

In Holland the connexion of *sanitation* with agriculture is far closer than with us and it is possible that we may derive some useful hints from our neighbours. In Holland the sanitary problems are of a formidable kind. The level of the country varies from a few feet above to a few feet below the mean level of the German Ocean, and it is needless here to recount how the Dutch people, marvellous for their shrewdness and untiring industry, have maintained a successful warfare against the forces of nature. With the exception of two or three inconsiderable areas the whole of the Kingdom of the Netherlands is a flat plain intersected at very frequent intervals by canals and rivers. These watercourses are all sluggish and in some of them the slow current is maintained artificially by pumping. It may be said that every Dutchman lives within a few yards of a watercourse of some kind, be it ditch or canal. These canals form a very cheap and admirable means of internal communication and in consequence the barge population is very large indeed. The population of Holland tends steadily to increase, such increase being most marked in the big towns.

In no country in Europe, probably, has the state of public health improved more remarkably than in Holland. This is well shown by the following table which is taken from the "Annuaire Statistique de la Ville d'Amsterdam," 1896. The decline of the death-rate has been uniform and continuous since 1884, but for the sake of conciseness the years 1877, 1880, and every fourth year thereafter alone have been given.

Nombre des décès (mort-nés exclus) par 100,000 habitants de la population moyenne dans les cinq grandes villes des Pays-Bas, années 1877-96.

Années.	Amsterdam.	Rotterdam.	s'Gravenhage.	Utrecht.	Groningen.	Les 5 villes.
1877	25,00	25,32	21,66	23,91	29,51	24,70
1880	27,00	24,65	23,38	27,10	24,39	25,74
1884	27,87	27,01	24,87	26,38	22,00	26,67
1888	21,82	21,26	20,11	22,56	20,04	21,38
1892	19,78	23,26	20,32	23,84	17,27	20,89
1896	17,77	18,27	16,27	19,04	16,01	17,65

The causes of this improvement in the death-rate are probably the same as have operated throughout Western Europe generally. These causes are: (1) the improvement in the physical and moral condition of the lower strata of society; (2) sanitation in its widest sense; (3) the rapid increase of population especially in the towns, causing a dilution of the high death-rates in the old crowded portions by the lower death-rates of new settlers in the outskirts; and (4) the decrease in the birth-rates. In Holland, as in England, the importance of pure water, especially for town populations, is abundantly recognised, and public supplies have within recent years been carefully protected from pollution and filtered before being distributed. The risk of drinking canal water must have been very great indeed. The mode of dealing with fæcal matters is necessarily different from ours. In Holland water-closets are the exception and not the rule and while the slop water of the houses is allowed to flow into the canals the fæces are collected and used for agricultural purposes. During a visit to Holland in September, 1898, I was able to obtain the Dutch death-returns for 1885-89 and for 1889-94, a period of 10 years in all. For this I have to thank Mr. Verryn Stuart, the secretary of the Statistical Commission at The Hague, who most courteously procured for me the volumes containing the returns in question.

Taking the population for 1885-94 at 4,500,000 the average annual death-rate is 18·26 and the typhoid fever and typhus fever death-rate is 0·13 per 1000.

It will be observed that in Holland generally the death-rate from enteric fever compares favourably with our own. Knowing as we do the great risk of drinking sluggish water liable to fæcal contamination (which has been exemplified in the Tees valley) the low enteric death-rate in Holland is not a little remarkable. Enteric being a fever of slow and insidious onset it is impossible in sporadic cases to say where or how the patient may have been infected and in cities with an ever-shifting population this difficulty is accentuated. That being the case it will not be without interest if I give a few particulars concerning the provinces of Groningen and Friesland which I visited in the vacation of 1898. These two provinces are almost entirely devoted to dairy farming, the breeding of horses and cattle, and agriculture. The shifting and travelling population is a small one and it is here if anywhere that we may learn the effect of local habits and customs on the public health.

The town of Groningen with 63,863 inhabitants is in point of population the fifth town in Holland and a reference to the table will show that the improvement in its death-rate in the past 20 years has been as remarkable as that observed in the other Dutch cities or in any town or city in this country. In this town as also in Leeuwarden, the capital of Friesland, and in the great majority of Dutch towns the fæcal matter is collected in pails and it is probable that in the whole extent of the two northern provinces of Groningen and Friesland there is not a water-closet to be found. The whole of the fæcal matter is scrupulously and religiously collected and returned to the soil. Dutch cleanliness is proverbial and certainly I have never been in a town so exquisitely clean as is the town of Groningen. The accumulation of ordure in the streets and backyards is simply not tolerated and the inhabitants coöperate with the scavengers in clearing away all refuse as quickly as possible. The collection of fæcal matter is very simple. The closet-pails are much smaller than those which are commonly used in this country and they are emptied twice or thrice a week or daily if the householder is ready to pay a small fee. The collecting cart is really a tank upon wheels with a sort of hood projecting behind like the hood of a carriage facing the wrong way. The pails are brought out, and the man and pail are hidden by the hood as the contents are simply tipped into the tank. The pails even when full being such as one man can lift easily the collection is probably ten times as rapid as is the case in those English towns which make use of huge two-man pails which weigh 50 lb. and more when empty. Again it is obvious that the Groningen authorities do not make the mistake of hauling about an immense weight of pails which adds enormously to the expense. The depot where the material is collected is on the outskirts of the town where a wharf has been constructed with a view to its removal by barge for the purposes of the farmer. Here, again, the arrangements are very simple. The stuff is simply stacked beneath rough sheds covered with corrugated iron. The men employed have found out exactly how to do it and by arranging a layer of street sweepings and rubbish (dung, straw, paper, rags, &c.) with peat ashes (the fuel used in this district is almost exclusively peat) alternately with a layer of pail contents the whole mass drains and consolidates into a very rich black manure which the farmer highly appreciates. The floor of the depôt is concreted and provided with channels so that the urine drains away into a large tank whence it is pumped into barges for the use of the agriculturist. Considering the work which went on in it, this depôt was wonderfully neat, the stacks were as evenly made as the best hay stacks, and the paths between them were quite free from befoulments. The smell from the putrid draining was, to say the least, powerful but the solid stuff soon ceases to be very offensive. There were large numbers of flies in this depot but I frequently remarked that the flies in the town of Groningen were not nearly so troublesome as is the case in cities less carefully scavenged.

---

[4] Journal of the Royal Agricultural Society, vol. viii., p. 469.

In the town of Leeuwarden the pails are taken to and from the depot but the pails are much smaller and lighter than those in use in England so that 54 of them (three tiers of 18 each) can be carried on a one-horse lorry. In the 10 years 1885-94 there were in each of the provinces of Groningen and Friesland 490 deaths from enteric fever and typhus fever, 980 deaths in all or an average of 98 per annum in a population of some 600,000, giving a rate for typhus fever and enteric fever of 0·16 per 1000. During the same period there were 97 deaths from the same cause in the town of Groningen and 27 in the town of Leeuwarden, or 124, giving a yearly average of 12·4. These figures are not large but they show that as regards these diseases the condition of Groningen was slightly worse than the town of Leeuwarden. As in England so in Holland, the death rate from enteric fever has been falling steadily and the returns for the last available year (1897) are very instructive. From these returns I find that in the province of Groningen with 296,521 inhabitants there were 23 deaths from enteric fever in 18 parishes, giving a death-rate of 0·03, and in the province of Friesland, with 339,425 inhabitants, there were 19 deaths from enteric fever in 12 different parishes, giving a death-rate of 0·056 per 1000. It is a remarkable and most interesting fact that in 1897 there was no death from enteric fever in either of the capital towns of Groningen or Leeuwarden, containing over 95,000 inhabitants (Groningen 63,663 and Leeuwarden 31,593).

The figures given above must be taken to show that in these two provinces there is no serious endemicity of enteric fever. When we consider that dairy farming is the staple industry of these provinces, that milk which is most sensitive to typhoid fever infection is everywhere abundant, and that human excreta containing a certain proportion of typhoid fever excreta are used, and have been used for ages, to manure this fertile district, which lies almost in the water, the comparative freedom from enteric fever seems remarkable and very full of instruction.

These facts seem to me to afford a very large measure of proof that there is no inherent danger in the methods of sanitation pursued in Groningen and Friesland and, in fact, in Holland generally. Dutchmen are eminently shrewd, thrifty, industrious, and methodical. The interiors of their dwelling-houses and cattle-houses are, as a rule, exquisitely clean and neat and on the farm one is constantly confronted with the same characteristics. In the agricultural districts nothing is ever thrown into the ditches or watercourses. On the contrary, everything is taken out of them that can be turned to profit. These ditches must be kept clean and the banks of them need constant attention. The banks are kept in repair largely by the mud which is removed from the ditch and whatever the ditch will grow in the shape of rush or weed or willow is all carefully harvested and turned to account for thatching or for litter or for basket work. The Dutch farmer never feels the effect of drought and this is one secret of his success. His endless watercourses serve for fences and afford a cheap and ready means of transport. They are a source of small profit in various ways and most certainly they are never allowed to carry away from the farm anything which possesses manurial value. The methods of the Dutch agriculturist are slow and sure and steady. He has had to contend with the forces of nature and has got the upper hand and is now ahead of the whole world in exacting labour and profit from wind and water.

The returns issued by the Board of Agriculture show that in 1896 we imported from Holland 923 horses, 663,196 cwt. of dead meat, over 500,000 cwt. of butter and cheese, 861,887 cwt. of margarine, 217,891 cwt. of milk and condensed milk, 375,116 bushels of fresh fruit (apples, pears, cherries, plums, &c.), and 1,581,386 bushels of onions. In addition we imported from Holland 509,710 cwt. of grain and 40,127 tons of hay and no mention is made of the horticultural products in the form of "Dutch bulbs," &c., which we import in enormous quantities.

In the United Kingdom of Great Britain and Ireland there are, including waste lands, 77,672,000 acres supporting a population of 40,000,000, and in Holland there are (excluding lakes and rivers) 7,786,000 acres supporting 4,894,000, so that Holland supports a bigger population per acre than the United Kingdom. In the United Kingdom the area under cultivation (crops and grass) amounted to 47,868,553 acres in 1897 and this figure appears to be slightly decreasing. In Holland in 1895 the total area under crops and grass was 5,149,817 acres, showing an increase of 95,000 acres in the preceding three years. In the United Kingdom there are 1·2 acres of cultivated land per head of the population and in Holland there are 1·05 acres of cultivated land per head of the population. Statistics prove that Holland is a most fertile and productive country, but one requires to travel through it in order to be fully impressed with the extraordinary amount of produce which the Dutchman exacts from the soil. In Groningen and Friesland one cannot but be struck with the well-to-do look of the population. If there be wretchedness and squalor it is not visible to the traveller and must be, in any case, relatively small in amount. The people are well nourished and well clothed, the towns are handsome and clean, and the shops are excellent. Perhaps no better evidence of the high-level of comfort which pertains in this purely agricultural country can be given than the fact (which I take from "Baedeker's Guide") that the town of Leeuwarden with 31,000 inhabitants supports 25 firms of jewellers and silversmiths who are mainly engaged in making personal and household ornaments for the farmers and their families. Let it not be supposed that the Dutchman owes his position of agricultural supremacy to the "natural" fertility of the soil of his country. Doubtless he has found a large amount of well-watered pasture land ready to hand, but it is undeniable that some of the very best of his land has been won from the sea, the desert moorland, and the bog, by indomitable pluck and perseverance. Above all, the Dutchman is fully impressed with the necessity of returning to the soil everything that comes out of it. Nobody knows better how to facilitate that circulation of organic matter which is a law of Nature and he sees that his profit depends upon the completeness and rapidity of that circulation and that in farming as in other businesses a rapid turnover of capital is to be aimed at. In Holland everything which has manurial value is religiously returned to the land and we find that the population is increasing as fast as ours and that the land under cultivation is increasing although the area of land is less per head in Holland than in the United Kingdom. The level of public health is as high in Holland as in the United Kingdom and an enormous amount of farm, garden, and dairy produce is exported to this country where (albeit that many a tract of bog and waste moorland is waiting for the subjugation of civilisation) the land under cultivation is tending to decrease, where manurial wealth is being recklessly burnt or turned into the sea, and where one-half of the population is absolutely ignorant of the uses and value of dung and the other half is, if not ignorant, too squeamish to use it.

It is very difficult to appraise the fertility of a district. The area of Friesland is given as 331,030 hectares, of which 206,718 are pasture and 47,317 are arable. These 254,035 hectares of land under cultivation are farmed by 14,049 farmers, of whom 5374 are freeholders. The average holding would thus appear to be 18 hectares or about 43 acres, and as one travels through the province the substantial farmhouses appear to be dotted over the country with something like mathematical precision and the cattle (of which there were 233,582 in the province in 1897) appear to be innumerable.

Groningen contains a considerable amount of waste land. The pastures are less extensive than in Friesland and there is a greater area under the plough. In 1897 I find that in Groningen 7351 hectares of wheat produced 35 hectolitres per hectare; 4702 hectares of barley produced 41 hectolitres per hectare; and 33,135 hectares of oats produced 57 hectolitres per hectare. These returns are large and are the equivalents of 40 bushels of wheat to the acre, 46 bushels of barley to the acre, and 65 bushels of oats to the acre. Agricultural returns for a single year are not, perhaps, of great value but these figures show at least that the land is capable of an enormous yield. The yield of oats especially appears to be very large.

The municipal accounts of the city of Groningen for the year 1897 show that the total cost of keeping the city clean was 94,596 florins (12 florins = £1). *The chief items of this expenditure were:—*

	Florins.		Florins.
Salaries and wages	50,615	Disinfectants	263
Horse hire	21,441	Sundries	4,177
Repairs to carts	4 507	Clearing snow	11,231
Boat hire .. .. - ..	1,500	Total	94,596
Brooms	812		

As a set-off against this expenditure the accounts show that the compost resulting from the stacking of ordure and refuse, which amounted to 1315 barge-loads, was sold for 58,075 florins, and the liquid manure which drained from the stacks and which is much valued by agriculturists was sold for 5339 florins. The total receipts from the sale of manure amounted, therefore, to 63,414 florins, which, [illegible] ducted from 94,596, gives *31,182 florins (say £2600)* as the net [illegible] cleaning Groningen. Taking the population of [illegible] cost of scavenging works out at something [illegible] head of the population. It will be noticed that of the total expenditure (exclusive of clearing snow) very nearly two-thirds go in wages, a great part of which is paid to the poorest class and must in some degree lessen the poor-rate. It appears that the permanent staff consists of 102 persons, of whom 56 with 28 horses and carts are engaged mainly in collecting ordure, and 20 people with 10 horses and carts in collecting ashes and refuse. For cleaning sewers, canals, gutters, and gratings 19 men are employed. The collection of ordure is done in the early morning before 10 A.M.

CARRINGTON MOSS.

This seems to be the place in which to allude to the spirited action of the city of Manchester which has reclaimed Carrington Moss and which is about to reclaim Chat Moss by fertilising the ground with the organic refuse of the city. The ground is a virgin peat which is admitted to be deadly to one at least of the supposed earth organisms. The experiment is a splendid one and will certainly be the precursor of similar action elsewhere. I have gathered some figures which may give an idea of the gigantic task with which the cleansing committee of the city have to grapple. From the report of the Cleansing Department of the city of Manchester for 1897 I find that 354,364 tons of refuse—very nearly 1000 tons a day—were disposed of. Stated in cartloads there were of street sweepings, 61,248; of "Bell dust," 9823; of rubbish, 97,658; and of night-soil, 240,781; total, 409,510. Of the material collected nearly one-third of the weight is lost by evaporation (in the preparation of concentrated manure), leakage, and drainage, and nearly 100,000 tons find their way to the rubbish tip, so that about 140,000 tons remain to be accounted for. Of this 49,342 tons were sent to Carrington Moss and over 57,000 tons were disposed of to farmers direct. Over 6000 tons of concentrated manure (made from 108,000 tons of "daysoil" or pail-closet contents) sold for more than £17,000. Nearly 19,000 tons were converted to mortar and were sold for £4500 and some 9000 tons of clinker were used for road-making. The net expenditure of the cleansing committee in 1897 amounted to £131,793 so that the 354,364 tons of refuse were dealt with at a cost of 7*s.* 5*d.* per ton. The total cost for the year of the Carrington estate (including rent and interest of capital) was £2482. The material sent to Carrington in 1897 consisted of 37,082 tons of nightsoil, 587 tons of sweepings and garbage, and 11,673 tons of cinders. The Carrington Moss estate, therefore, regarded merely as a dumping ground for garbage and refuse, must be a source of satisfaction to the Cleansing Department of the city of Manchester.

On August 11th, 1897, I visited Carrington Moss and had the advantage of being shown over it by Mr. McConnell, the bailiff. Carrington Moss was bought by the Manchester Corporation in 1886. It is 10 miles from the city, in close proximity to the famous Chat Moss from which it is separated by the Manchester Ship Canal which serves for the transit of material from Manchester. The estate, for which the corporation gave £38,000, has an extent of 1100 acres, of which 600 were wild moss commanding a rental of a shilling an acre for sporting rights. The corporation has spent £56,000 on light railways, roads, drainage, rolling-stock, buildings, &c., making the cost £94,000. (The outlay on the estate is given as £82,946 in the City Treasurer's Abstracts, 1897.) In the nine years 1889-97 491,686 tons of refuse material have been placed upon Carrington Moss, or very nearly 50 tons per acre per annum. The moss has been drained by a series of deep trenches with nearly vertical sides cut at regular intervals. The refuse as it arrives from Manchester is transmitted by means of a light railway to various part of the estate where for the most part it is placed in heaps and allowed to "ripen" before being placed upon the ground. These heaps soon cease to be in the least offensive. Nightsoil is frequently applied directly to the fields. At the time of my visit two barges estimated to contain 80 tons of refuse were unloading at the little wharf which has been especially constructed. The hay harvest was just over and the corn harvest was soon to commence. The crops one and all were in splendid condition. Oats, potatoes, carrots, wheat, and all the other usual farm crops appeared to be first-rate, quality excellent, quantity enormous. The roads were hard and firm having been brought to this condition by the application of clinker and other forms of hard material from the city. The farm is not quite a dead level but the inequalities of the surface are very slight so that from every point the spectator is able to survey an area of very considerable extent. Without previous knowledge there was nothing in the appearance of the farm (except the deep trenches) to indicate the character of the subsoil. All indications of bog had completely vanished. On reaching Mr. McConnell's house we walked out upon a pretty lawn surrounded by a flower-border brilliant with carnations and the ordinary garden plants. The lawn was firm and perfectly dry and I was not prepared for the demonstration which I was to have of the character of the subsoil. Taking an iron rod having a length of 11½ feet and a diameter of about half an inch Mr. McConnell with one hand drove it through the turf of his lawn completely up to the handle. I then did the same thing. As the rod passed through the first foot or so there was some resistance and a sense of grittiness was imparted to the hand, but this first obstruction passed the descent of the rod was progressively easier until it was finally stopped by the handle resting on the lawn. On withdrawing the rod the lower half was found to be wet while the upper part was dry. To the upper half clung a little grit and peaty earth, the lower half was clean but wet. It was then only that one recognised that this fertile paradise was literally floating.

Mr. McConnell informs me that Carrington Moss is everywhere about 12 feet in depth and that the variations in depth are very slight; whereas Chat Moss, although distant only a few miles, has a depth which varies from four to over 30 feet. On Chat Moss where the digging of drainage trenches was in progress I examined the peat which had been removed. These trenches are dug to a depth of about four feet to begin with. The peat near the surface had the ordinary fibrous character, whereas that from the bottom appeared to the naked eye to be smooth and structureless and saturated with moisture. It looked like brown jelly. The moss resembles a huge sponge. Mr. McConnell states that the surface of Carrington Moss is gradually sinking; that whereas when first he came to live on the estate he could, from a certain point see the spire only of a neighbouring church, he can now see the slates upon the roof. The sponge is being squeezed and drained, and rendered more compact. The half million tons of garbage which has been placed upon the surface must exercise considerable pressure and must serve to squeeze moisture into the deep trenches. Then, again, the upward drainage of the abundant crops is obviously very large indeed. The amount of moisture retained and evaporated by an acre of oats or mangel must be very great.

There are, as yet, not many trees upon the estate, but part of it, about 43 acres, is used as a nursery for the shrubs required for the parks and cemeteries of Manchester. These nurseries appeared to be most flourishing and contained a large variety of shrubs. The rhododendrons were extremely vigorous. Mr. McConnell assured me that the farm as a place of residence is by no means damp and that the rain which falls upon his lawn quickly drains away to the reservoir beneath and leaves the surface dry. He and his family and the employés on the farm have always enjoyed excellent health. There has been one case of enteric fever in nine years, the cause of which is doubtful.

Of the 1100 acres of land occupied, 372 acres are farmed by the committee, 639 acres are let to tenants, and the rest is occupied by roads, wharves, plantations, &c. The rental of the portion which is let amounts to £1516 19*s.*, or about £2 7*s.* 6*d.* per acre, while the rent of the amount retained by the corporation is put in the accounts as £933 (i.e, £2 10*s.* per acre for the 372 acres farmed, or just £2 if the roads, &c., be included). In the year 1897 on the 372 acres farmed by the corporation there were produced: clover and clover hay, 430 tons; carrots, 250 tons; oats, 5500 bushels; potatoes, 2500 loads; swedes, 90 tons; mangolds, 90 tons; and straw, 200 tons. The value of this produce would appear in the accounts for 1898. In the year ended March 31st, 1897, the value of the farm produce amounted to £3632 or about £9 15*s.* per acre while the net profit on the farm appears to have been £1041 or £2 16*s.* per acre. The amount paid in wages was £1520 and the rent, as stated, was £933. If we may assume, as we have every right to assume, that the land rented was as productive as the land retained by the corporation, then the value of the produce of the 1011 acres under cultivation would, at £9 15*s.* per acre, amount to £9864 and we then arrive at the conclusion that each of the 49,342 tons of refuse sent to Carrington Moss in 1897 produced almost exactly 4*s.* worth of food. But now that the Moss is entirely reclaimed it will not take more than 30 tons of stuff to the acre, or, say, 30,000 tons per annum. Thus by a well-considered expenditure Manchester has provided itself with (*quâ* refuse) a destructor capable of dealing with about 100 tons per diem for ever and in its formation this machine has absorbed nearly half a million tons of refuse of which the city had of necessity to be rid at all costs. When the loans necessary for the purchase and development of this estate have been paid off it is certain that Carrington Moss Farm will cost the Manchester ratepayer nothing and will probably yield a return in crops of about 6*s.* 8*d.* for every ton of refuse used. Land which produced nothing and which let for 1*s.* per acre has been made to yield nearly £10 worth of produce and an eventual rental of £2 10*s.* per acre. This is a grand result and one of which Manchester may well be proud.

I am well aware that in farming, where results depend so largely upon the weather, it is hazardous to calculate returns on the yield of a single year, and that anything under a 10 years' average is likely to mislead. On the other hand, £10 worth of produce from an acre of land is no excessive return. My visit to Carrington Moss left upon me the impression that much of the land is ready to pass, as some has already done, from the hands of the farmer to that of the market gardener. In that case, when oats, grass, and carrots and mangels give place to fruit and high-class vegetables, it is certain that, with a market like Manchester at its door, the money value of the crops in Carrington Moss may be doubled or quadrupled. There is probably no city in the world where excreta are dealt with by methods other than water-carriage on so large a scale as they are dealt with in Manchester. In 1897 the city had an area of 12,911 acres; it contained 534,299 inhabitants living in 105,728 dwelling-houses, or rather over five persons to a house. There were 76,913 pail-closets, presumably used by some 384,565 persons who provided 189.585 *tons* (nearly 425,000,000 lb.) of "pail contents." It would appear from the Cleansing Committee's accounts (p. 36) that at the Holt Town Works 108,394 tons of "day soil" were converted into 6304 tons of concentrated manure, and that for the production of this manure were used 4897 tons of coal and coke and 1674 tons of chemicals. Adding the weight of the chemicals to the weight of the "day soil" we arrive at the fact that 110,068 tons of raw material and chemicals were reduced to 6304 tons by the aid of 4897 tons of coal. Or we may say that 6571 tons of fuel and chemicals produced 6304 tons of manure from 108,394 tons of raw material. The amount of water and other volatile matter driven off amounted to to 103,764 tons. The price paid for chemicals (£5093) and fuel (£675) amounted to £5773 while the net profit on the sale of manure amounted to £2031 (p. 15).

It is instructive to compare the Holt Town Works concentrated manure accounts (p. 14 15) with the Carrington Moss Farm accounts (p. 28-31). At the former a turnover of £30,533 resulted in a profit of £2031, or rather more than 6½ per cent., while at the latter a turnover of £6202 resulted in a profit of £1041, or very nearly 17 per cent. Turning to the City Treasurer's Abstracts we find that whereas the Holt Town Works (p. 50), upon which the outlay has been £111,318, are now valued at £71,429, the Carrington Moss estate, upon which the outlay has been £82,946, is now valued at £118,617, so that while £39,889 of capital have been lost at Holt Town £35,671 have been made at Carrington.

CONCLUSIONS.

I have brought forward a considerable number of facts to prove that the dangers of applying dung to the soil are as nothing in comparison with the advantages—advantages which have been acknowledged from the dawn of historic time till now. It remains to say a few words on the financial side of the question. The great experiment at Manchester seems to prove conclusively that even in a huge city and with the heavy outlay which seems to be inseparable from all modern municipal undertakings a well-considered scheme of application of offal and ordure *in a dry state* to the soil is the most economic way of getting rid of it. I have shown how in Holland great cities may be kept spotlessly clean and in spite of obvious difficulties the public health be maintained by a well-devised system of scavenging. The cleanliness of Groningen is a thing which is scarcely realisable by one whose ideas of street sanitation are acquired in the West End of London, and the economy with which the scavenging is accomplished seems astounding to the London ratepayer. I have further shown that Holland with a smaller area of cultivated land in proportion to population than England is able to export to this country enormous quantities of farm and dairy produce and that while the English farmer can scarcely exist the Dutch agriculturist thrives and grows rich.

It will not be uninteresting, perhaps, if I give some of the financial results of my small experiment at Andover which is now in its fourteenth year of trial. In this experiment the ordure and house refuse of about 100 persons have been removed and applied *daily* for gardening purposes. The amount under the spade is now exactly one acre one rood and seven poles and I should like to say that the quantity of fæcal matter at the disposal of my gardener by no means satisfies him. I am also convinced that the garden might take with advantage at least double the quantity if not more. There is no evidence after a long experience that the soil is overdone. On the contrary, its "condition" has steadily improved. The produce of my garden has been sold on the principle of profit-sharing, so that the gardener is interested in extracting the greatest amount of produce from the soil. During the past year careful accounts have been kept, and I find that the produce fetched £71 19*s*. 6*d*., which works out to £56 per acre. Of this sum £41 12*s*. 7*d*. were received for fruit and £30 6*s*. 11*d*. for vegetables. Some of the chief items were as follow:—Apples and pears, £18 0*s*. 6*d*.; summer fruit, £17 1*s*. 11*d*.; peaches (out-door), £3 19*s*. 2*d*.; potatoes, £6 3*s*. 4*d*.; cabbage and cauliflower, £5 18*s*. 3*d*.; tomatoes (out-door), £2 3*s*. 0*d*.; asparagus, £2 1*s*. 1*d*.; and flowers, £2 2*s*. 5*d*. The method of agriculture which I pursue is well known, but this has caused no prejudice against the garden produce, which finds a very ready market.

Except in the vacation I certainly do not visit Andover more than once a month. My experience leads me to say that it is to me almost inconceivable that the daily scavenging of our towns should not yield enough profit to pay the wages. It is especially to be noticed that the yield of this garden has undergone steady increase and I have every hope that such increase will continue. But it would be a great mistake to suppose that an acre of ground cultivated and manured as my garden is is going to yield £50 worth of produce per annum at once. The test of true gardening is *increase*. With the lapse of years and without appreciable cost the increase of fruit trees is automatic and the yield of seeds is equally automatic and prodigious. My garden has gradually become fully furnished and to a large extent with its own offspring, and in that fact lies part of the secret of its increasing yield. What we see in the London parks in the summer is not "gardening" but a beautiful display, after the manner of the bouquetiste, of the results of gardening elsewhere. In the same way the filling of flower beds with a crowd of named and fashionable plants bought for the season is not gardening but a mere evidence of wealth. The real gardener in these cases is the nurseryman.

The gradual increase in the yield of a plot of land, at least for a very long series of years, is limited only by the amount of skill and tillage which it receives and the amount of dung which is available for it. All evidence goes to show that organic manure in the form of dung is absolutely necessary for the maintenance of the fertility of the soil. We are gradually becoming alive to the fact that fertility is a biological question rather than a chemical question. To imagine that chemicals can ever replace dung is a pure delusion from which we shall some day be aroused. The success or failure of agriculture is very largely a question of dung and it must be admitted that the dung prospects in this country are very bad indeed. Imported animal food yields very little dung for the land because it is mostly washed (ultimately) into the sea, while steam-engines and motor cars and bicycles must mean a diminution of horse dung. The sanitary pioneers of half a century ago thought that the huge expenses of modern sanitation would be compensated by the yield from sewage farms. That has proved to be a delusion. Sewage has proved to be merely the happy hunting ground of sanitary tradesmen who have fattened on the ratepayer. The century closes with the spectacle of a Royal Commission still discussing the best way of *destroying* the potentialities of life and prosperity.

In these lectures I have brought forward many facts to show that there is no proof of any danger arising from the use of dung for agricultural purposes, while it is undeniable that the practice of agriculture is pre-eminently healthy and invigorating. I have been unable to find any evidence that contagia spread in the soil. To live in filth and to inhale the products of putrefaction given off from privies or pails of fæces or sodden ground results in disease, but there is no evidence whatever that disease thus generated is able to spread through the soil and infect a neighbouring house or street. Looked at in another way we must admit that filth disease like many other forms of disease is proportionate to overcrowding. We may pave the backyard and provide it with a trapped gully (not always sweet) and we may wash the fæces into a ventilated sewer which then delivers part of its vapours near our bedroom windows. It is a difficult problem and there are *pros* and *cons*.

While we exult (not always reasonably) in our diminished death-rate, let us not forget the diminished birth-rate, the multiplication of asylums of various kinds, and the steady increase in the amount of help from public funds which is necessary to maintain the health and decency of the masses. The year just ended has been unsurpassed in the volume of trade and in the bounty of the harvest, but the infant mortality in our towns for the Michaelmas quarter was the highest on record. Yes; there are *pros* and *cons!* At present he who advocates any attempt to entice a fair proportion of the people "back to the land" is regarded as a Utopian dreamer. I feel convinced that the only chance of getting a living from agriculture lies in the due enrichment of the soil. There is no chance of this so long as the only form of sanitation which receives any official encouragement is one which involves a systematic starvation of the soil. One sometimes comes across statements which would lead one to suppose that cultivated land is a public danger—statements which are mere assertions. Some of our sanitarians careless of food-supply, are liable to be dominated by ideas and to fix their attention unduly upon one side of a question and upon one disease. The more enthusiastic of them, if they can secure a trifling dimination in the mortality of one disease, seem quite ready to "make a [illegible] and call it peace."

ABSTRACT OF

The Arris and Gale Lectures

ON

THE ANATOMY AND SURGERY OF THE PERITONEAL FOSSÆ.

Delivered before the Royal College of Surgeons of England on Feb. 27th and March 1st and 3rd, 1899,

By B. G. A. MOYNIHAN, M.B., M.S. Lond., F.R.C.S. Eng.,

ASSISTANT SURGEON TO THE LEEDS GENERAL INFIRMARY.

LECTURE III.[1]

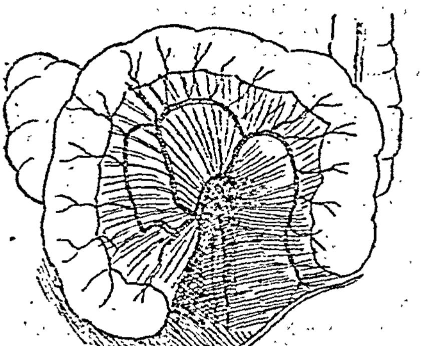
Delivered on March 3rd, 1899.

The Intersigmoid Fossa.

Mr. President and Gentlemen,—The first mention of the intersigmoid fossa is made by Hensing in the year 1742 in a Giessener dissertation. No subsequent reference to it is found until 1843. In this year Roser speaks of having seen the fossa very clearly defined on two occasions. In 1857 Engel describes a canal having a length of three centimetres in infants, extending along the inner border of the left psoas muscle to the level of the bifurcation of the aorta and in exceptional cases as far up as the pancreas. Treitz in 1857, Gruber in 1859, and Treves in his "Hunterian Lectures" give good descriptions of the fossa. The latter author says that "the perfect fossa was met with in 52 per cent. of all subjects. But if distinct funnel-shaped depressions be added to the examples of the true fossa then the percentage reaches 65." Jonnesco in 1890 and Brösike in 1892 give accurate accounts of the fossa.

On drawing the sigmoid or omega loop upwards the left or under layer of the sigmoid mesocolon is exposed. On this surface can be seen the entrance to the intersigmoid fossa at the line of insertion of the mesocolon (Fig. 8). The fossa is present in rather over 70 per cent. of bodies examined. Its frequency depends, however, chiefly upon the ages of the subjects. In the fœtus of later months and of infants it is invariable. Its frequency becomes less with increasing years. As Treitz showed many years ago, in the aged there are never lacking signs of adhesion, crimping, and thickening in the sigmoid mesocolon. Processes of this kind tend to obliterate the fossa, so that in subjects over 50 years of age the pouch is not infrequently wanting. The opening of the fossa is situated in the line of attachment of the sigmoid mesocolon *at a point which is near the inner margin of the psoas*. It lies over the common iliac artery close to, or in front of, its bifurcation. The orifice is generally round or oval and is bounded in front by a fairly well-defined sharp edge of peritoneum. In this edge, or very close to it, may be seen the sigmoid vessels. This orifice leads to the intersigmoid fossa which lies behind the sigmoid mesocolon and in front of the parietal peritoneum. The posterior wall of the fossa is adherent to the common iliac artery and through the transparent wall can be seen the ureter as it crosses the vessel. The apex of the fossa extends upwards for a distance that varies very considerably. Sometimes there is merely a dimple representing the fossa; in other cases the depth may be two or three inches or even more. I have on several occasions seen the fossa extend beyond the middle of the kidney and this is usually the case in the fœtus. Engel, Brösike, and Rogie describe the pouch as extending as far up as the body of the pancreas. Most frequently the fossa in the adult is of the shape and size of an abbreviated glove finger for an average middle finger.

Fig. 8.

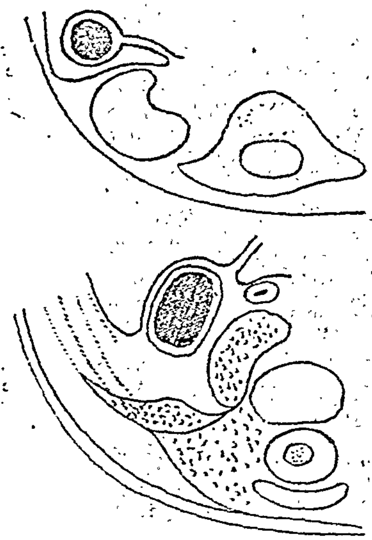


The intersigmoid fossa.

Genesis of the Fossa.

Several explanations have been suggested by Treitz, Luschka, Waldeyer, Treves, and others which I believe to be incorrect. It was first shown by Toldt that the disappearance of the mesentery of the descending colon was due to a process of "physiological adhesion" taking place between the left (or posterior) layer of the mesocolon and the parietal peritoneum (Fig. 9). This agglutination begins above close to the splenic flexure and spreads gradually downwards. Over the kidney, owing to the projection of this organ, the fusion is earlier and more complete. Along the inner edge of the kidney is a groove and here, therefore, the opposing surfaces do not so readily come into contact and adhesion is delayed. At the lower part of the groove union is never complete and the gap that results is the intersigmoid fossa. On examining a fœtus of the seventh month or a little younger the descending mesocolon is obliterated. On pulling, even gently, on the colon, however, it will be found to strip up quite readily from the parietal peritoneum until the primitive mesocolon is reproduced.

Fig. 9.



Formation of intersigmoid fossa.

Hernia into the Intersigmoid Fossa.

Treitz refers to two cases of intersigmoid hernia, one recorded by De Haen and the other by Lawrence. The description and figures given by De Haen negative his case unconditionally. Lawrence, in the fifth edition of his work, says that hernia may occur in the mesentery of the sigmoid, but gives no case. A case which has been generally accepted is recorded by Jomini. I have elsewhere[2] analysed this case which is probably one of gross congenital abnormality with secondary adhesion processes. It cannot be allowed as a hernia of this class. The only two authentic cases, so far as I am aware, are recorded—the first by Mr. F. S. Eve and the second by Mr. McAdam Eccles. Mr. Eve's case was described and figured in the *British Medical Journal* of June, 1885, and I must refer the reader to this article for full particulars. In that case the most likely explanation of the history seems to me to be this. There had been originally a common mesentery for the jejunum, ileum, cæcum, and ascending colon. The splenic flexure and the descending colon became fixed in the usual manner by adhesion of the left or posterior layer of the original descending mesocolon to the parietal peritoneum of the posterior abdominal wall. As a result of peritoneal adhesion, most probably pathological, the cæcum and ascending colon had adhered to the descending colon and the sigmoid and the united gut had been dragged over to the right, laying bare and rendering patent the orifice of the inter-sigmoid fossa.

---

[1] Lectures I. and II. were published in The Lancet of March 4th, 1899.

[2] On Retro-peritoneal Hernia. London: Baillière, Tindall, and Cox. 1899.

Mr. McAdam Eccles's case occurred in 1895. I am indebted to him for a reprint of his account in the "St. Bartholomew's Hospital Reports." The symptoms were those of acute intestinal obstruction. On opening the abdomen "a tightly constricting edge which afterwards proved to be the margin of the aperture of the inter-sigmoid fossa" was revealed. A loop of gut four inches in length was nipped in the fossa and about half an inch of it was gangrenous. The loop was removed and the ends were stitched by Maunsell's method. The patient died from exhaustion. At the post-mortem examination there were signs of "some general peritonitis, most marked in the region of the sigmoid flexure, which was itself thrown over to the right side of the body."

These two cases illustrate as well as possible two quite opposite conditions. In the one there was congenital abnormality, gross in extent, and peritoneal adhesion, probably pathological and extra-uterine, and in the other a peritoneal cavity in all respects normal.

HERNIA INTO THE FORAMEN OF WINSLOW.

This form of hernia is very uncommon. I have been able to find only eight cases recorded, four very imperfectly by Rokitansky, Treitz, Moir, and Novello, and four more fully by Blandin, Majoli, Elliot-Square, and Treves. After reading carefully the reports of those cases it seems to me almost certain that in order to permit of the occurrence of this form of hernia there must be some extreme congenital abnormality. Thus in Treitz's case there was "a common mesentery for the intestine from the duodenum to the rectum." In the cases recorded by Elliot-Square and Treves there was an absence of the secondary fusion process between the ascending colon and the posterior abdominal wall. The causes leading to the formation of this form of hernia are probably: (1) a common mesentery for the whole intestine (Bogie has collected 53 examples of this and he has not included all the cases); (2) absence of the secondary fusion of the ascending colon to the posterior abdominal wall, (3) abnormally large size of the foramen of Winslow; and (4) abnormal length of mesentery and consequently undue mobility of the intestine. In the absence of one or other of these abnormalities the occurrence of the hernia may be considered almost a physical impossibility.

SYMPTOMS.

On analysing the series of cases it seems that a hernia into the foramen of Winslow on becoming strangulated presents a fairly well-defined group of symptoms. These are. 1. Pain. This is generally epigastric. Elliot-Square speaks of "pain over the ensiform cartilage and immediately below it"; Treves of "pain like cramp at and above the umbilicus"; and Majoli of "a painful rounded tumour" in the epigastrium. 2. Tumour. An epigastric tumour has usually been observed. Thus Majoli says that "a persistent bulging of the anterior abdominal wall in the epigastric region" was present. Treves speaks of "a conspicuous bulging of the anterior abdominal wall in the epigastric and hypochondriac regions." Elliot-Square says that "the umbilicus was somewhat prominent." 3. Percussion. A tumour when present is dull on light percussion, but deep percussion sounds a more resonant note. It is interesting to note that there are no recorded symptoms of pressure on the hepatic artery, portal vein, or bile duct.

X RAYS: IMPROVEMENTS IN APPARATUS.

BY JOHN MACINTYRE, M.B. GLASG., F.R.S. EDIN.

WORKERS in the x ray department have long felt that improvement in the interrupters of coils was necessary before any great advance could be made. That many have attempted this is known, but it will surprise some to learn that the well-known firm of Apps have designed and constructed some hundreds of different forms on their own behalf and that of others. In a paper published by me in the *Archives of Roentgen Rays* attention was drawn to the more important forms and the principles involved, but I concluded by stating that a perfect interrupter had not yet been made. It is with great pleasure therefore that I call the attention of the readers of THE LANCET to an important discovery described by Dr. Wehnelt of Charlottenburg in the *Elektrotechnische Zeitschrift* of Jan. 22nd, 1899, and add that English readers are indebted to the editors of the *Electrical Review* of Feb. 17th of this year for an excellent article on the subject. The principle involved is described as follows: "If a current be sent by means of two electrodes of unequal surface through an electrolyte, the electromotive force applied being considerably greater than the counter electro-motive force of polarisation, well-known light and heat phenomena may be observed on the electrode with the smaller surface. The latter is called the active electrode." Planté and others have observed and worked at this subject long ago, but Dr. Wehnelt has investigated the question as to whether there is a complete interruption or merely a reduction of the intensity. His conclusions have led him to utilise this chemical interrupter with marvellous results. From the description given I have had an instrument constructed. It consists simply of a glass beaker six inches high and four in diameter containing diluted sulphuric acid 25° B. In this is placed a sheet of lead measuring six inches by four inches. The other electrode is simply a thin piece of platinum wire measuring a few millimetres in length fused into the bottom of a glass tube. This tube can be filled with mercury to make contact, or a piece of copper wire may be attached to the end of the platinum which projects into the test tube. The object of the tube is to sink the platinum sufficiently into the fluid to prevent spluttering. I have used the current from the mains with the 100 volt circuit and the current from the positive wire goes to the platinum electrode. The moment the current is turned on it is noted that the meter registers something between five and 10 ampères when using an 18 inch Newton's coil; also that an arc of a most extraordinary description passes between the discharge rods of the coil, and that this arc seems to be composed of a torrent of sparks practically continuous although the length is diminished about from 10 to 12 per cent. The noise made is quite unlike that of any other interrupter and indicates a very high frequency. It is said in some instances to amount to 1500 per second.

It is premature to speak of the modifications, but it is quite evident that we are able by this extraordinary interrupter to vary the frequency of the break, and it may be noted in passing that as the break increases the voltage increases, hence the coil is protected. The amount of the current can also be varied by differing the proportions of the size between the platinum and lead electrodes.[1] One of the great difficulties in working coils in the past has been to obtain sufficient frequency to give a continuous light on the screen and rapid exposures, as it was found that when the interruptions passed from 1500 to 2000 per minute fluorescence could no longer be obtained. With the new arrangement, however, flickering on the screen is entirely done away with and certainly the results obtained in this direction by me have been as good as those previously seen with the Wimshurst machine. Not the least important advantage obtained is cheapness, and from what I have already seen I should say that we are nearer the complete utilisation of the induction coil than at any previous date. It would appear that smaller coils will now be capable of demonstrating and photographing structures hitherto beyond their range. It may be added that the difficulty of moving parts employed in many other interrupters has been entirely removed. Further it may be subsided and the pains "all over the body" were somewhat relieved; but there was constipation (for which some simple saline aperient was given), complete loss of appetite, flatulence, and a bad taste in the mouth. On the 26th the temperature was very slightly subnormal and the pulse was 48; the gastric symptoms were as well marked as on the previous day. As the patient was subject to repeated attacks of double otorrhœa and as a severe headache had recurred I thought for the moment that some meningeal mischief might be impending, but the absence of other more pronounced signs and symptoms soon dispelled my apprehension and made me inclined to think that jaundice might develop, the more so since the skin and conjunctivæ showed a slight yellowish tint, but the tests for biliary pigment in the urine gave a negative result. I discontinued the cachets and prescribed small doses of quinine in an acid vehicle. The condition remained much the same for the next two days, but on the 29th the patient felt so well that he got up in opposition to my advice. This was followed by a further decline in the pulse-rate from 45 to 40. I sent him back to bed, but it was not until after the lapse of five days that the pulse rallied though stimulants had been freely given. There was a feeling of profound prostration which did not subside until the pulse was 56 or 58. The patient was kept in bed till Feb. 5th and he has recovered since though there is still some general weakness left.

---

[1] So complete is the break that the condenser is rendered superfluous.

CASE 2.—The patient was a woman, aged 27 years, who had never been ill before. On Jan. 28th she fell ill with shivering, violent vomiting, headache, pains in the back and limbs, and pains in the stomach, soon followed by severe diarrhœa. The temperature was 97·4° F. and the pulse was 56. On the 29th the prostration was so well marked that she fainted when sitting up in bed. The temperature was 98° and the pulse was 48. On the morning of the 30th her condition was the same, but there were now constipation, flatulence, furred tongue, a very bad taste in the mouth, and pains behind the eyes. Under the free use of stimulants she made a rapid recovery so that she was able to leave her bed on Feb. 3rd. The pulse showed a marked reaction, 82 being counted at the wrist.

CASE 3.—The patient was a woman, aged 48 years, who, though subject to gout, was otherwise healthy. She first sent for me on Jan. 31st when I found her very prostrate, with pains all over the body, anorexia, a furred tongue, dry lips, constipation, flatulence, and cough. The temperature was 99° F. and the pulse was 80. On Feb. 1st, the bowels having been relieved, she felt somewhat better though she was extremely weak. The heart was beating at the rate of 60 per minute and the temperature was 97°. During the following days the pulse rate was gradually reduced to 45, while the temperature was subnormal, varying between 96° and 97·2°. Champagne was ordered in large doses and brandy was given at regular intervals. On the 5th the pulse showed some improvement and on the 8th the patient was able to leave her bed, the pulse-rate being 68 and only some weakness remaining.

I may add that in these three cases, as well as in several others in which there was marked bradycardia, though not so extreme as in those described, all the organs were healthy and there was not the least sign of heart disease. In my experience the pulsus rarus is most pronounced in those cases where there is influenza of the gastro-intestinal type. Of course, bradycardia is frequently observed in states of exhaustion, particularly during convalescence from acute fevers. But in influenza bradycardia is not only met with during convalescence from a severe attack but as an essential sign on the height of the paroxysm. It is usually accompanied by a subnormal temperature, though there is no necessary relation between the range of temperature and the pulse-rate. But in the absence of all other signs there is very marked prostration inversely proportionate to the frequency of the heart-beats. I do not think that the slowing of the pulse is the outcome of the general weakness or *vice versâ*, but that both bradycardia and constitutional exhaustion are the result of the same cause—the poisoning of the system with the products of influenza or of the influenza germs, for I have not the least doubt that the pulsus rarus is due to the immediate action on the pneumogastric nerve or on the ganglia of the heart by the influenza toxins and bearing this in mind it is imperative to keep the patient in the recumbent position, though all other indications of the disease have disappeared, until the pulse has rallied in order to give the heart the highest possible degree of physiological rest.

ST. MARYLEBONE INFIRMARY, NOTTING-HILL, W.

TWO CASES OF IDIOPATHIC DILATATION OF THE COLON.

(Under the care of Mr. JOHN R. LUNN.)

THAT there are cases in which portions of the large intestine are found enormously distended and yet no source of obstruction is discoverable is now generally admitted, but the true cause of this curious condition is doubtful. It is often attributed to chronic constipation which is always found in these cases, but the constipation is in all probability the result and not the cause of the dilatation. The nervous theory is the most inviting. One curious point is that the dilatation is sometimes limited to a part of the colon and does not involve the whole of the large intestine. The fact that the muscular walls are in some cases at least distinctly hypertrophied indicates that there has been increased pressure in the bowel, but the true significance of this fact is not clear. For the notes of the cases we are indebted to Dr. H. Sinigar, assistant medical officer.

CASE 1.—A woman, aged 86 years, was admitted into St. Marylebone Infirmary in October, 1897, for bronchitis, but she was found to be also suffering from marked abdominal distension. She was a well-nourished woman who, owing partly to the bronchitis and partly to the abdominal distension, had to be propped up in bed. She gave a history of simple constipation with no attacks of diarrhœa and no loss of blood from the bowel. There was enormous distension of the abdomen which was tympanitic all over and not tender. Peristaltic action of distended coils of gut could be distinctly seen through the abdominal walls; no tumour was felt in the abdomen. Rectal examination revealed ballooning of the rectum, absence of rectal stricture or growth, and the presence of an enlarged, hard, and globular uterus of about the size of a fist. She had considerable bronchitis, the heart's apex beat was displaced outwards, and there was an apical systolic murmur. The liver and spleen were not enlarged. The constipation was successfully treated by enemata and castor oil. Charcoal was given by the mouth with the view of lessening the distension, but without any beneficial effect. She remained in the same condition for some months, complaining at times of abdominal pain which always appeared to be due to a temporary increase of the distension. She died from bronchitis and heart failure in March, 1898.

Necropsy.—On opening the abdomen at the post-mortem examination the distended coils were seen to consist of large intestine only, the small gut lying hidden behind. The distension began at the cæcum and included the whole length of the colon and rectum. The transverse colon was much increased in length and was tortuous. No growth, stricture, or compression of any part of the intestinal tract could be discovered. The mucous membrane appeared to the naked eye to be normal everywhere and the muscular coats were only slightly thickened. There were no scybala in the colon or rectum nor was there any evidence in the gut of previous fæcal impaction. The circumference of the distended colon was about 15 inches. The uterus was retroverted and contained a calcified fibroid, but this was not so large as to fill up the pelvis. There were no marked changes in the other viscera.

CASE 2.—A woman, aged 66 years, was admitted into St. Marylebone Infirmary for obstruction of the bowels on Oct. 11th, 1898. She was very emaciated, with an anxious expression, sunken eyes, dirty complexion, and sordes on the lips and tongue. The history obtained from her husband was that she had been fairly healthy until six years before admission. Then she began to be troubled with flatulence and obstinate constipation She had for many years been in the habit of taking aperients regularly She had been gradually losing flesh for five years, during which time the abdomen became more and more distended She had never passed any blood from the bowel Vomiting began a fortnight before admission On admission the abdomen was greatly distended and tympanitic all over, no tumour was felt She vomited frequently, the vomit consisting of an offensive dark brown fluid The rectum was ballooned and was full of soft semi liquid fæces, no stricture or growth was discovered There had been no action of the bowels for a week, so a large enema was given at once, but was retained Another enema which was given a few hours later was also retained Vomiting continued and soon became feculent, her general condition at the same time getting steadily worse As soon as the patient's friends could be seen it was decided to open the colon for drainage purposes The operation was begun 36 hours after admission and as the patient was very feeble it was performed on the bed A 5 per cent solution of eucaine was injected and a small incision was made in the left iliac fossa Large intestine at once presented in the wound, but owing to the enormous distension no attempt was made to pull out a loop of gut and thus the actual condition found post mortem was not realised at the time of the operation The presenting gut was stitched to the abdominal wound and opened four hours later Large quantities of flatus escaped and the abdomen soon became flaccid, but very little fæcal matter was discharged There was no shock from the operation, the patient died 26 hours later

Necropsy—At the post mortem examination a most remarkable condition presented itself on opening the abdomen Rising up from the pelvis for 13 inches above the symphysis pubis was a greatly dilated rectum which occupied the whole of the front of the abdomen The only other part of bowel visible was the sigmoid flexure which had been opened at the operation The rest of the large intestine and the whole of the small intestine were hidden behind the dilated rectum The first part of the sigmoid flexure was only moderately distended and the lower part was both distended and lengthened, from the brim of the pelvis it turned sharply upwards and passing in front of the descending colon it reached as high as the splenic flexure of the colon, then it was again turned sharply on itself and at that level became continuous with the rectum The gradual broadening of the longitudinal muscular bands of the sigmoid flexure until they formed a complete coat of longitudinal muscular fibres in the rectum was remarkably well seen, at the lowest part of the sigmoid flexure these bands attained a width of one and a half inches, and even then were quite distinct from each other The arrangement of the longitudinal muscular fibres as a complete outer covering, and not as three separate bands, showed that the dilated gut was rectum and not sigmoid flexure Although quite flaccid the circumference of the rectum at the level of the umbilicus was 26 inches Its muscular walls were hypertrophied the longitudinal fibres on the anterior surface were especially well marked The rectum contained a very large quantity of semi liquid fæces and appeared to be capable of holding as much as a domestic bucket No scybala were present The mucous coat was somewhat thickened, there was no ulceration of its surface

Remarks by Dr SINCLAIR—These two cases are examples of so-called idiopathic dilatation of the colon occurring as Treves[1] points out independently of mechanical obstruction in adults, thus differing from dilatation of the colon in children which he believes to be due to some congenital defect in the lower gut As regards the causation of this rare condition Hale White[2] points out that chronic constipation is probably not in itself a sufficient explanation, if it were so one would expect to find the condition more commonly in women, whereas 11 out of 12 cases reported have occurred in men He is inclined to regard the condition as analogous to non obstructive dilatation of the stomach Case 2 reported above certainly seems to me to support his view In this case the dilated rectum descended practically in a straight line from the diaphragm to the anus and kinking of the sigmoid or rectum which was suggested as a cause in some of the published cases, could not possibly have occurred as the rectum almost entirely filled the abdomen It is, of course, possible that excessive action of the sphincter may have caused difficulty in the expulsion of the rectal contents, but it is worthy of note that in neither case did the examining finger meet with any resistance at the anus Then, again, the descending colon was of normal calibre and the transverse and ascending colon were actually rather less than the normal size—a fact difficult to understand if the kinking view be accepted The analogy to dilatation of the stomach is further strengthened by the marked impairment of the absorptive power of the colon, as in both cases the fæces were semi liquid. On the whole it seems to me that some anomaly of the innervation of the affected gut is a not unreasonable explanation of the condition In Case 1 the chief trouble was bronchitic and as an action of the bowels could always be caused by enemata or aperients and as the case was diagnosed as one of idiopathic dilatation of the colon it was not considered advisable to resort to any operative measures Case 2 presented an entirely different clinical picture The symptoms were obstructive and urgent and were regarded as due to malignant disease Colotomy, however, gave no relief since the opening in the bowel was entirely above the collection of fæces in the rectum. The great capacity of the rectum easily explained the inefficacy of the enemata I am indebted to Mr Lunn, medical superintendent of the infirmary, for permission to publish these cases

PATHOLOGICAL SOCIETY OF LONDON.

Discussion on "Pseudo Tuberculosis"

A MEETING of this society was held on March 7th, the President, Dr PAYNE, being in the chair

Professor JOHN MCFADYEAN, in continuing the discussion on Pseudo Tuberculosis, agreed with speakers on the previous occasion who considered the term "pseudo tuberculosis' unscientific and open to objection But it was often extremely difficult to say positively if a lesion were true tubercle as there were no macroscopical or microscopical characteristics which were absolutely distinctive and there were fallacies even in the bacteriological examination owing to some bacilli having similar staining reactions In practice, however, a trained inspector, who had special experience of the appearance of tuberculous lesions in any particular species was very likely to be wrong in basing his diagnosis on the naked eye appearances and general characteristics, less likely if he employed histological and bacteriological methods of investigation, as it was often extremely difficult to demonstrate the presence of the tubercle bacillus in an undoubtedly tuberculous specimen and to discriminate it from other bacilli As an example, he had met with a bacillus in milk which stained exactly like the tubercle bacillus but which was distinguished from it by its morphological characters There were many true tuberculous lesions which were difficult to recognise, of which illustrations were shown on the screen with the lantern The first was a specimen of villous like projection over the peritoneal surface of the liver which contained capillaries and giant cells at the periphery The second was a specimen of tuberculous mastitis in the cow where the appearances were those of a diffuse cirrhosis of the gland There were also many conditions to which the term "pseudo tuberculosis' had been applied of which he showed the following specimens 1 Small pin head shotty nodules occurring in the lung of the sheep, in which the microscope showed the presence of an undetermined worm in the centre surrounded by leucocytes and these by giant cells The resemblance to tubercle was increased by the tendency to softening of the centre 2 Grey patches from the lungs of the sheep, a scraping from which showed abundance of embryo worms and ova 3 The so called 'scrofula' of sheep which affected the glands of the head and face which formed abscesses The septum nasi was covered with nodules which had the same structure as tubercles but contained a different bacillus which could be cultivated Neither the culture, however, nor the pus itself gave rise to similar lesions if inoculated 4 "Bacterial necrosis in the liver determined by the special "necrosis bacillus." The necrotic area was subsequently invaded by leucocytes and the true nature of the lesions was often very obscure. 5. A nodule in the lung of the horse due to the growth of a mycelium.

[2] Clifford Allbutt's System of Medicine, vol iii where a complete bibliography may be found

Mr. **ALEXANDER FOULERTON** said that it was a fallacy to suppose that there was anything truly characteristic about the tubercle follicle and he believed that a similar lesion might result from the action of many different bacilli on the tissues. He thought that each tubercle should be distinguished by the name of the bacillus by which it was produced and not as true and false. An abscess might be produced by many organisms, yet they did not speak of an abscess due to one particular organism as true and of those produced by others as pseudo-abscesses. The diagnosis of phthisis was usually made in the post-mortem room on the strength of the naked-eye characters, but bacteriological confirmation was necessary before such cases could be labeled as tuberculous. It had been shown, especially in France, that there were a few cases which, clinically indistinguishable from phthisis and having the same morbid appearances, were in reality due to the presence of an aspergillus, and cultures of this aspergillus inoculated into a rabbit gave rise to lesions exactly similar to those produced by a culture of the tubercle bacillus. The smegma bacillus could be distinguished from the tubercle bacillus by contrast, staining in a concentrated alcoholic solution of methyl violet. There were sometimes bacilli in milk, as Professor McFadyean had said, which could not be decolourised and they would have to be distinguished by culture and inoculation. Mr. Foulerton brought forward specimens showing general infection in the guinea-pig by cultures of pathogenic yeasts, the resulting lesions microscopically and macroscopically resembling tubercles. Mr. Foulerton proposed the appointment of a committee to devise some nomenclature for the forms of granulomata which had been included under the term "pseudo-tuberculosis" and the society appointed the President, Professor McFadyean, Professor Woodhead, Mr. Shattock, and Mr. Foulerton to act on the committee.

Mr. **W. O. O. PAKES** referred to aspergillosis as one of the forms of disease to which the term "pseudo-tuberculosis" had been applied. He observed that the presence of moulds in sputum from cases of supposed phthisis was not very rare and it occurred in some in which the tubercle bacillus could not be found, and some of these might be really cases of aspergillosis and not of tuberculous phthisis. He thought that this might be an explanation of certain cases which cleared up very quickly.

Dr. **LAZARUS-BARLOW** was not sure whether the term "pseudo-tuberculosis" should be altogether dropped. It was useful as showing the close resemblance to tubercle and could be used just as the term "counterfeit sovereign" was used. The lesion might be (*a*) anatomically (*b*) clinically (*c*) bacteriologically indistinguishable. For example, the condition of the lung which often proved fatal in diabetic patients closely resembled tuberculosis, but in many instances the tubercle bacillus could not be demonstrated and in these the term "pseudo-tuberculosis" was convenient. Dr. Lazarus-Barlow pointed out that it was often very easy to miss the tubercle bacillus and to attribute causation to other factors unless very laborious investigations were made and mentioned a case in which he made a necropsy. The appearances were those of caseous pneumonia, apparently tuberculous, but on microscopic examination he found that there was a mycelium spreading through the tissue which must have been present at the time of death, as the specimen had been kept in strong spirit. No tubercle bacilli were present in the specimens first examined but he continued his search for them and it was not until he had mounted the forty-ninth that he discovered the presence of the tubercle bacillus.

Dr. **F. J. WETHERED** said that in 1891 he had the opportunity of investigating "pseudo-tuberculosis," the material being obtained from two cultures of the bacillus which had been sent from Paris. At first there was some difficulty in obtaining pure cultures, but this was eventually accomplished by means of plate cultures. The characteristics of the bacilli and colonies were the same as those already described by Dr. Sims Woodhead. The guinea-pigs inoculated died between the ninth and twelfth day. In every case an abscess formed at the site of inoculation. Those inoculated from pure cultures showed small white nodules scattered through all the organs which on naked-eye and microscopic examination simulated the appearances seen in miliary tuberculosis. In one animal there was no enlargement of the glands, but in others this condition was well marked. Unless microscopic and bacteriological examination had been made the conclusion would have been that the animals died from miliary tuberculosis and if it were a common disease errors might very easily be made during investigations in which guinea-pigs or other animals were employed.

Dr. **WOODS HUTCHINSON** agreed that the word "pseudo-tuberculosis" was in the scientific sense an absurdity, but it was difficult to get any practical substitute. The discussion had shown that observers agreed that there was an enormous preponderance of the true form and that the doubtful cases were few. But the term had the great convenience that it did not commit the observer prematurely to a statement of what the cause of the lesions was. Much inconvenience had resulted from the hasty adoption of terms expressing supposed causation, since the terms persisted when their significance was proved to be erroneous, as in the case of the term "uræmia," and although the term "pseudo-tuberculosis" was scientifically indefensible it had the advantage of not expressing anything very definite and from its clinical convenience he thought that it would last.

The **PRESIDENT** said that the lesions which had been under discussion appeared to have only one common feature—viz., that they imposed on observers as being tubercle, and the observer, feeling proud of his own acuteness in escaping from the error, gave them a name which drew attention to his acuteness. But the term was one which need no longer be kept up. He agreed with Mr. Foulerton that a variety of micro-organisms would produce a structure exactly like the tubercle follicle, but he would go farther and say that any irritant would do it provided it was sufficiently small in amount and local in its action. Theoretically, for example, a sufficiently small drop of acid would produce similar follicles, and in practice, in the affection known as ophthalmia nodosa, in which such follicles developed on the sclerotic or conjunctiva, the irritant had been shown by Mr. Lawford to be the hairs of a caterpillar in one case and by Baumgarten to have been due to the hairs of a mouse in another. In these cases the irritant had no power of reproducing itself, but with any irritant capable of reproduction lesions closely resembling miliary tuberculosis were possible. With reference to the occurrence of appearances resembling tubercle the President mentioned specimens which he figured in the Transactions of the Society for 1870 in which an immense number of minute nodules having a fibrous structure were found scattered over the peritoneum and scattered over the liver.

Professor **WOODHEAD** replied.

The following card specimens were exhibited:—

Mr. **FOULERTON**: Myoma of the Œsophagus.

Dr. **LAZARUS-BARLOW**: Aneurysm of the Splenic Artery and Traumatic Rupture of the Trachea.

Professor **JOHN MCFADYEAN**: Congenital Tuberculosis in the Calf.

Dr. **ROLLESTON**: Aneurysm of the Splenic Artery, Myoma of the Œsophagus, Myxoma of the Thigh weighing 10 lb., and Gastric Ulcer (albuminuric) in Granular Kidney.

OBSTETRICAL SOCIETY OF LONDON.

President's Address.—Primary Carcinoma of the Fallopian Tube.—Exhibition of Specimens.

A MEETING of this society was held on March 1st, Mr. **ALBAN DORAN**, President, being in the chair.

The **PRESIDENT** began the Inaugural Address by showing how the Obstetrical Society of London had from its earliest days taken the deepest interest in gynæcology, now a well-established speciality which had rendered important services to general surgery. Uterine therapeutics and minor gynæcology were associated with abuses, but so were medicine and surgery. They were indispensable and must be well understood because, as in the case of the abscess knife and the catheter, "minor" proceedings with the curette, the sound, and other special instruments were liable to cause grave damage if unskilfully performed. The President specially dwelt on the judgment of gynæcological surgery on general surgical grounds and insisted that good operating was not always good surgery. Plastic surgery had made great advances since 1859. Vaginal hysterectomy for cancer seemed to be good surgery as compared with the cancer practice of the general surgeon. Ovariotomy proved the key to modern peritoneal surgery. Drainage and flushing of the peritoneum were intimately associated with it, the latter in turn was closely related to transfusion as now understood. In operations for diseases of the appendages due to inflammation a skilful and successful operation might be decidedly bad surgery, or else questionable surgery, or else very good surgery. Exploratory incision was often needed in chronic cases; sometimes it was sufficient to liberate the ovaries and tubes from the painful bondage of adhesions, sometimes only one tube and ovary needed ablation. On the other hand, bilateral suppuration of obstructed tubes of course demanded removal of both. Bad after-results chiefly arose from the pedicle, the tissues of which were often unhealthy, and not from the uterus. In reporting a series of the sccases a long after-history was needed. Foreign authorities were very careless about this matter, thus one operator publishes tables where eight operations were performed within six weeks of the reading of the paper. They seem also far too ready to remove the uterus with the diseased appendages. One operator living in a relatively small capital has performed this operation over 500 times in a very few years; his mortality was low but no reliable after-histories were given. Recovery in this class of operation was for obvious reasons no proof that the removal of the parts was necessary, whilst in bad cases where the operation was good surgery the results were not always entirely satisfactory. The removal of ovaries for neuroses was almost universally condemned. Weir Mitchell had categorically declared that the whole principle of such a proceeding was wrong. The surgery of uterine fibroids had greatly progressed, but much more had to be learnt. Fibroids of the broad ligament needed early removal, so did uterine fibroid in a very young subject or in a case near the menopause where there was rapid increase of growth and manifest softening. When in doubt the surgeon should always wait; bleeding and slowly-growing fibroids allowed of watching and palliatives. Speculative operations where the fibroid was small and caused neither severe hæmorrhage nor pressure symptoms were not good surgery. In the field of uterine displacements there were many abuses. A long series of operations had been devised to fix the uterus up in its right place or to support it from below. The variations in opinion and practice showed that much remained to be settled. The President thought that even the pathology of displacements was yet obscure, nor did certain operations overcome the essential morbid condition associated with a flexion or version. Hysteropexy in well-selected cases was beneficial, but as in operations for chronic disease of the appendages long after-histories were needed but were not always furnished in papers written by operators. Surgery must respectfully follow clinical exploration, otherwise not only the surgeon's knife but his power of diagnosis would be blunted by too many exploratory incisions. Patient clinical research was the sheet-anchor of the gynæcological surgeon and surgical proceedings were only justified when clinical research had proved that there was something which ought to be removed or rectified by an operation.

Mr. HUBERT ROBERTS read a paper on a Second Case of Primary Carcinoma of the Fallopian Tube. The case occurred in a married woman, aged 60 years, who had never been pregnant. There was no history of pelvic trouble. The menopause occurred at the age of 50 years. She was perfectly well up to June 27th, 1897, when she first noticed a cherry-coloured watery discharge which lasted three days. Nothing was noted on vaginal examination. On July 3rd, 1897, the discharge recurred and was more profuse but of the same character, lasting two days. In September, 1897, there was very severe abdominal pain followed by another rush of watery fluid. Repeated pelvic and abdominal examinations during the latter months of 1897 revealed no tumour. In the spring of 1898 a fourth attack of watery discharge occurred with severe pain. On April 3rd, 1898, a swelling was first discovered behind and to the left of the uterus. Subsequent examination at the end of April confirmed the presence of a tumour which had grown rapidly and the preliminary diagnosis of a malignant ovarian tumour was made. Abdominal section was performed on May 5th, 1898 The tumour proved to be an enlarged Fallopian tube filled with growth. The operation was one of great difficulty owing to many adhesions and the tube ruptured during the operation. The ovary on the same side was cystic but not infiltrated with growth. The appendages on the other side were healthy. There was no secondary growth or infiltration of the pelvis at the time of operation or any free peritoneal fluid. The patient recovered from the operation. In November, 1898, a favourable report was received of her condition, but early in January, 1899, she was not so well and examination proved that there was already well-marked recurrence of malignant growth in the pelvis.—The PRESIDENT remarked that carcinoma of the tube certainly arose from papilloma such as occasionally developed in an old hydrosalpinx. Mr. Roberts's case seemed to be of that type. In the tables which he himself had prepared[1] the patients were 60 years old in two out of a total of 25 cases and between 56 and 59 in two more. He thought that Doléris was correct in distinguishing an endo-salpingitic papilloma and had himself demonstrated the relation of papilloma to inflammation as long ago as 1879 and noted the malignant degeneration of papilloma in 1888. He had recently come across a case of papilloma of the tube associated with malignant tumour of the broad ligament. He doubted whether cancer had ever been seen to develop in a previously healthy tube.—Dr. CULLINGWORTH said that the question as to the connexion between papilloma and carcinoma could scarcely be settled until an opportunity occurred of examining a carcinomatous tube at an early stage. He (the speaker), notwithstanding that he had had a fairly large experience in tubal affections, had not as yet happened to meet with a single example.—Dr. AMAND ROUTH alluded to a case of primary carcinoma of the Fallopian tube which he had reported to this society. He doubted whether these cases began with papilloma, the microscopic section showing nothing in common with the forms of malignant papilloma which he had seen invading the uterine wall.—Mr. ROBERTS said that he had not been able to find any case recorded below the age of 38 years. He believed the pain to be due to the distension of the tube by fluid which when the tension rose above a certain limit escaped as a cherry-coloured discharge He thought it quite possible that the case started in an old hydrosalpinx, though there was nothing in the previous history to show this. It was very difficult, if not impossible, to distinguish between papilloma and carcinoma of the tube.

The following specimens were shown:—

Dr. SMYLY (Dublin): Three Myomatous Uteri removed per vaginam by Doyen's method.

Mr. BLAND SUTTON: (1) A Ruptured Ovarian Tumour and (2) an Acardiac Calf.

Mr. A. LIONEL SMITH: An Infant showing Diffused Subcutaneous Induration.

Dr. DAKIN: A Fibro-myoma Spontaneously Enucleated during Labour.

HARVEIAN SOCIETY OF LONDON.

Vanishing Tumours.—Exhibition of Specimen.

A MEETING of this society was held on March 2nd, Mr. HENRY JULER, President, being in the chair.

Mr. D'ARCY POWER read a paper on Vanishing Tumours which was published in THE LANCET of March 4th.

The PRESIDENT referred to the case of a woman who had been under his care in whom both eyeballs were protruding and there was extensive anæsthesia about the forehead and almost complete blindness. In each orbit an indurated mass could be felt at the outer canthus and below the globe. The growths were believed to be malignant and a portion of one of them which was removed for microscopic examination presented appearances which were believed to be sarcomatous and not gummatous. After a few months' treatment with mercury and iodide of potassium the tumours entirely disappeared. They were in all probability gummata.

Mr. ALBAN DORAN suspected that Morrant Baker's "withering sarcoma" of the scalp was akin to the fibromas of the abdominal wall, a large specimen of which he had himself removed from the sheath of the rectus that very day. They caused danger by their size, but sometimes disappeared spontaneously. Reed of Cincinnati had reported one case where the tumour seemed to be irremoveable when exposed by the knife; the skin wound was closed and the tumour, certainly a fibroma, disappeared. Mr. Doran knew of a case where a patient refused operation for what seemed to be a fibroma of the abdominal wall. She became pregnant and the tumour vanished. The majority of vanishing tumours in the abdominal cavity itself were simply cases of tuberculous peritonitis. When a "cyst" was diagnosed and a circumscribed collection of serum bounded by intestine bearing old tuberculous deposit was laid open by the knife it was apt to be mistaken for a cyst of the urachus or for a malignant ovarian tumour with metastatic deposits. Even after long experience the surgeon often found such a case very puzzling. But it nearly always got well. Mr. Doran had seen perfect cure follow incision in a number of cases where he had designedly incised the peritoneum for the relief of tuberculous disease and also in two instances where he suspected the dense deposit in the parietal peritoneum to be malignant. He had never known of a case of exploratory incision where real sarcoma or carcinoma was detected which had benefited in the least by such interference.

---

[1] Transaction place Obstetrical Society of London, 1898.
898.

Dr. F. M. COCK mentioned the case of a widow, aged 71 years, who was feverish. On examination a hard mass was found reaching from the right pelvic wall to the lower border of the liver, easily defined from side to side, not doughy to the touch, and extremely tender. The uterus was partly fixed and there was a bloody discharge. Purgatives had no effect nor were there any symptoms or signs of fæcal accumulation. Consultants were of opinion that the mass was carcinomatous. After an illness of 10 weeks the patient became better, the mass shrank, and at the end of a six months' holiday at the seaside the patient returned quite well with no tumour and ultimately died five years afterwards from bronchitis.

Mr. EASTES referred to the large number of vanishing tumours which were associated with various parts of the organs of generation (male and female), including the female breast. A striking instance was furnished by fibromata of the uterus occurring in middle life. He had seen a uterine fibroid (as large as a pregnant uterus towards the end of gestation) disappear almost entirely within a year after cessation of menstruation and the patient recover health, though previously she had nearly died on several occasions from excessive "monthly floodings." But the vanishing tumours most often seen in general practice were probably fæcal accumulations in the colon. One patient who found aperient remedies always produce pain and consequently neglected them had twice within the last two years allowed such an accumulation to occur and passed through a severe illness before she was relieved. She probably had adhesions; at any rate, there was a history of peritonitis in childhood with constipation ever since. During each of these later illnesses the cylindrical accumulation in the ascending colon measuring six inches in length and four inches in diameter had occupied a fortnight in vanishing, and several days in that period some 10 or 12 distinct, hard, almost spherical masses of fæces had to be removed by the finger or large enemata from the rectum. The medicine which had accomplished the removal in the last illness was a pill composed of resin, podophyllin, and extract of belladonna, an eighth of a grain of each in each pill, given once, twice, or thrice daily according to the necessities of the case.

Dr. LEONARD GUTHRIE believed that there were well-authenticated instances of the spontaneous disappearance of tumours both malignant and benign. The causation of this was of greater interest than the occurrence. Mr. Alban Doran had mentioned a case in which a large abdominal tumour disappeared after ligature of its principal vessels. Perhaps this was the clue to the whole mystery. Tumours were dependent on their blood-supply for their growth. If the blood was cut off the tumour would waste. In most cases this result could not be effected by surgery, but possibly the vaso-motor system might at times cause local constriction of vessels and thus retard the growth of tumours. The phenomena of Raynaud's disease showed that vaso-motor action was capable of producing local gangrene. Possibly the success which occasionally attended the treatment of cancer by drugs depended on their action as vascular astringents. In the last century cancerous breasts were treated by the application of toads which were supposed to suck the venom from the ulcers. But Dr. Lauder Brunton had compared the action of phrynin, the active principle of the secretion of toads' skin, to that of digitalis and erythrophlenin which were powerful vascular astringents. Phrynin has, moreover, a benumbing action on sensory nerves, like aconite. Hence although the remedy seemed absurd it might possibly have been beneficial in some cases. A similar explanation might be offered of the effects of other drugs vaunted as cures for cancer: for instance, carbonate of lime, chian turpentine, and cinnamon, which latter contained tannic acid. Finally, the success which sometimes followed oöphorectomy f[illegible]ble cancer of the breast was possibly due to the profound effect produced by that operation on the whole of the sympathetic system. Perhaps in such cases a local dilatation of vessels in a cancerous region gave place to a local constriction. The effects of strong mental emotion on the sympathetic should not be forgotten. This might account for the miraculous cures of cancer and tumours at Lourdes and elsewhere. But all methods of treatment based on these assumptions were at best uncertain and their effects were but temporary; they were only available in inoperable cases.

Dr. WASHBOURN mentioned some observations which had been made by Mr. Bellingham Smith and himself upon infective sarcomata occurring in dogs and which they had published in the Transactions of the Pathological Society and in the *British Medical Journal*. The sarcomata were originally situated in the mucous membrane of the vagina and penis and were transmitted from animal to animal during the act of coitus. They consisted of round cells with an alveolated arrangement and were similar in structure to the round-celled alveolar sarcomata met with in the human subject. By inoculation they could be transmitted to the subcutaneous tissue of dogs. At the end of two or three months the resulting tumours reached their maximum development, forming lobulated masses about two inches in diameter. They then took one of two courses. Either they became disseminated, secondary nodules appearing in the internal organs causing the death of the animal, or they disappeared. In the latter case they either slowly dwindled away, being replaced by fibrous tissue, or they disappeared by a process of ulceration. A most interesting point was the fact that after the tumour had disappeared the animals were absolutely immune to subsequent inoculations. Up to the present time no micro-organisms bearing a causal relationship to the tumour had been discovered.

Mr. D'ARCY POWER replied.

Mr. BELLAMY GARDNER showed an Improved Ether Inhaler which he had devised. Its advantages were—(1) a breathing channel two inches in diameter; (2) a reservoir for six ounces of ether, the quantity required being emitted upon a sponge by simply turning a tap; and (3) compactness and portability in the filled condition. He had used it in over 700 cases in the past two years and a half and recommended it as combining the advantages of Clover's and Ormsby's inhalers.—In answer to questions by Dr. COCK and Mr. EASTES Mr. GARDNER stated that the supply of ether could be easily regulated and that with ordinary care there was no fear of any fluid entering the face-piece.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Peritonitis.—Etiology of Gout.

A MEETING of this society was held on March 1st, Sir JOHN BATTY TUKE, President, being in the chair.

Dr. W. ELDER showed a man exhibiting the Absence of the Fifth Metacarpal Bone in the Left Hand. A radiograph showed that the carpal bones were correct in number but misplaced, while the ring and fourth finger were both articulated to the enlarged head of the (apparently) fourth metacarpal bone. Dr. Elder also showed a man suffering from Amyotrophic Lateral Sclerosis. The signs began to show themselves about 12 years ago. The disease usually affected the arms, but in this case the legs showed the changes. Both feet were markedly clubbed and inverted. The knee-jerks and ankle-clonus were present.

Mr. HAROLD STILES exhibited (1) a boy, aged 12 years, who showed in a marked degree the severe results of Infantile Paralysis; (2) a child, aged seven months, with a very large Hydrencephalocele; and (3) a child with Coxa Vara.

Dr. SCOT SKIRVING and Dr. CAMERON showed a man with Total Necrosis of the Frontal Bone. The patient was 52 years of age and had contracted syphilis 35 years ago. No treatment had ever been carried out. He married two or three years after infection and yet his wife was never affected. He was the father of three healthy children. The whole of the anterior half of the calvarium was wanting and the brain was seen pulsating over this area. The orbital plate on the right side was gone and the upper surface of the eyeball was evident. He did not suffer from any secondary symptoms of the disease. Seven years ago the hard palate became perforated.

Mr. STILES exhibited (1) the Viscera from a case of Lympho-sarcoma of the Abdomen which simulated abdominal tuberculosis clinically; and (2) the Thoracic Viscera from a Child who suffered from Severe Dyspnœa with Expiratory Stridor and in whom there was found at the post-mortem examination an enlarged gland of the size of a small walnut pressing on the lower end of the trachea.

Dr. SCOT SKIRVING showed a specimen of Tuberculosis of the Mamma which occurred in the right breast of a girl, aged 18 years, and a specimen of Compound Fracture of the Carpus.

Mr. CATHCART exhibited a Clinical Research Case which he had devised for use at the bedside.

Mr. CATHCART read a paper entitled Peritonitis as a Cause of Increased Peristalsis in the Rectum and Lower Part of the Intestine. He related the case of a healthy married woman, aged 37 years, who during menstruation developed a follicular tonsillitis. She recovered apparently from this but was seized a few days later with a sudden sharp pain in the pelvis. There was constant tenesmus but no fæces passed. It was thought that she was suffering from an impaction of fæces at the sigmoid flexure and the collapse which she presented was similar to that seen sometimes in simple colic. The patient died suddenly 30 hours after her first seizure At the post-mortem examination an acute recent pelvic peritonitis was found and streptococci were present in the fluid. Death had resulted from septic poisoning. Another case was that of a healthy young married woman, aged 26 years, five months advanced in her first pregnancy. 10 days previously to her being seen she thought she had caught a chill and suffered from such difficulty in micturition that a catheter had to be used. During a motion of her bowels she felt what she described as a great lump which suddenly came down the back passage. Every few minutes spasms came on, the whole body being involved just as in labour and the mucous membrane of the rectum was everted. It looked like an impending abortion but the uterus remained unaffected. A lump was noticed in the perineum and being resonant it was diagnosed as a hernia. Under chloroform reduction was attempted but unsuccessfully. During the night much fœtid fluid and gas escaped through the vagina, showing that a perirectal abscess had burst. The patient miscarried a week later. In this case the cellulitis round the rectum had produced intense tenesmus. Mr Cathcart's work in the lock wards had shown him that proctitis caused frequent action of the bowels and dysuria. During the disease the rectum never regained its tone, the anus remaining patulous. The same condition (gaping anus) was seen in many cases of enlargement of the prostate. It was probably only partially true that the strain in emptying the bladder in such cases caused strain in the rectum; there was probably also a reflex action. Another case related was that of a young man who was operated on for fœtid abscess of the vermiform appendix He remained well for 10 days, then became dull and apathetic. The abdomen became distended and the temperature rose but not the pulse. He lost control over his fæces and the anus became patulous. A fœtid collection of pus was found to be present in the pelvis round the rectum. On opening the abscess the patient recovered. This case was related to show that irritation round the rectum caused increased peristalsis. Certain writers had noted this as a cause, as Potts in 1762 and Ashton in 1857, while others (and especially recent writers) do not refer to it. It had been experimentally shown that peritonitis caused peristalsis in the small intestine. This increase in peristaltic action was later replaced by paralysis which first showed itself in the large intestine. Dr. Gee, in the Bradshaw Lecture of 1892 on the Signs of Peritoneal Disease, said that there was really no difference between the cause of pain in colic and that in peritonitis. Peritonitis caused colic and so there was pain as an early symptom of this affection. The mechanism must act at first through the nervous system, but when the muscular coat became involved this could no longer exert influence and paralysis came on. This increased peristalsis was not present in all cases of peritonitis. The form of irritant might have an important action and again a sufficiently large area of the rectum might require to be involved in order to produce this diarrhœa.

Dr. CHALMERS WATSON read a paper on the Etiology of Gout. After criticising the various definitions of gout he gave a rapid summary of the chemistry of uric acid. In contradiction to Dr. Garrod and Dr. Luff he had found that uric acid was present in the blood of birds and consequently deductions based on the fact that uric acid was not formed in the blood must be untrustworthy. The liver was found to contain a larger absolute amount of uric acid than other organs. Dr. Watson had not found any evidence to support the view that the kidney was the main seat of formation of uric acid.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

Effects of Sodium Chloride on the Secretion of Urine.—The Seventh Cranial Nerve.—Anæsthetics and Urinary Secretion.

A MEETING of this section was held on Feb. 3rd, Dr. D. J. COFFEY, the President, being in the chair.

Professor W. H. THOMPSON read a communication dealing with the Effects of Minute Quantities of Sodium Chloride on the Secretion of Urine Solutions of sodium chloride (0·6, 0·65, and 0·9 per cent. strength) were injected into the external saphenous vein of dogs in quantities varying from 30 c.c. to 50 c.c. Urine was collected from both ureters by means of cannulæ. The animals were given a hypodermic injection of morphine and were anæsthetised with a mixture of chloroform and ether. The result was a marked increase in the amount of urine secreted, far exceeding the amount of fluid injected. Both the total nitrogen and the urea also suffered an increase.

Dr BIRMINGHAM read for Professor DIXON of Cardiff an abstract of a paper on the Sensory Distribution of the Seventh Cranial Nerve in Man. Professor Dixon considered that the facial nerve in man was in a condition comparable with what was found in lower vertebrates. It clearly resembled in its distribution what had been called a typical branchial nerve. The facial possessed two sensory branches—namely, the chorda tympani and the great superficial petrosal nerve. Both of these nerves were probably nerves of taste; the chorda tympani certainly was so, but this had not been definitely proved in the case of the great superficial petrosal nerve.—The PRESIDENT thought the question of the nerve of taste one of the most difficult in connexion with the physiology of the nervous system.—Professor SYMINGTON said that with regard to the distribution of the chorda tympani and the great superficial petrosal, on theoretical grounds he should be in perfect harmony with Professor Dixon.—Dr. A. R. PARSONS said if the course which the taste fibres took were known with certainty it would be a great aid in the localisation of disease.

Professor W. H. THOMPSON made a preliminary communication on Anæsthetics and Urinary Secretion, of which the following is a brief summary:—1. A mixture of ether and chloroform (two to one) did not cause an increased diuresis. This was the anæsthetic used in his sodium chloride research. Six experiments were performed on dogs. 2. A C.E. mixture, on the contrary, did in most cases markedly increase the amount of urine. In one case suppression was caused. This dog proved to have albuminuria. 3. Ether also produced an increase of urine, as did chloroform likewise, but with this latter anæsthetic only one experiment had so far been carried out. 4 Little or no effect was produced by the various anæsthetics on the total output of nitrogen and of urea, even in cases where marked diuresis was caused. 5. The after-effect on the output of chlorides showed a marked diminution. What the immediate effect was had not been so far definitely decided. 6. In eight experiments (with different anæsthetics) the urine was examined for carbohydrates with chloride of phenylhydrazin and sodium acetate. All but one gave crystals. Some of these were undoubtedly glucosazone, others glycuronic acid, while in one case it was probable that the crystals were those of galactosazone. In all cases the dogs were injected with a solution of morphine.

SECTION OF OBSTETRICS.

Rotunda Lying-in Hospital Report.—Exhibition of Specimens.

A meeting of this section was held on Feb. 10th, Dr. F. W. KIDD, the President, being in the chair.

A discussion took place on the Rotunda Hospital Obstetrical Report for 1898.

Dr. **More Madden** said the record was most creditable. He believed that this was due to the strict asepsis practised in the hospital. Dr. Purefoy had set a good example in the use of ergot in post-partum hæmorrhage.

Dr. **W. J. Smyly**, referring to accidental hæmorrhage, said that the best treatment was still practised—namely, that if the patient had not strong labour pains it was a mistake to rupture the membranes and if there was external hæmorrhage the uterus should be plugged. In London students taught at the Rotunda had been rejected at examinations for not saying that they would rupture the membranes in such cases. Even the nurses who went up for the examination of the Obstetrical Society were instructed beforehand to say, if asked what they would do in a case of accidental hæmorrhage, that they would rupture the membranes, which, he thought, would be most improper.

Dr. **Macan** pointed out that the mortality of the internal department was, contrary to what they would expect, twice that of the external department.

Dr. **Purefoy**, Master of the Rotunda, in reply said that with regard to the use of ergot in post-partum hæmorrhage it was needless to say that they only used it when the placenta was absent. One possible explanation of the fact that the mortality was greater in the internal than in the external department was of course that the bad cases in the external maternity were admitted into the hospital.

Specimens were exhibited by Dr. **Emily Winifred Dickson**, Dr. **W. J. Smyly**, Dr. **F. W. Kidd**, and others.

Manchester Clinical Society.—A meeting of this society was held on Feb. 21st, Dr. A. Hill Griffith, President, being in the chair.—Mr. F. Bowreman Jessett (London) opened a discussion on the Operative Treatment of Malignant Disease of the Breast and Uterus. He referred to the bad results which had followed operation by the older methods owing to the inperfect knowledge of the mode of spreading of carcinoma and sarcoma and to the ignorance of the anatomy of the lymphatic system. It was only during recent years that the importance of free and wide removal of the disease had been recognised. The researches of Mr. Harold Stiles and of Heidenhain as to the way in which many of the lymphatics of the breast enter the pectoral fascia and pectoral muscle were referred to. Malignant disease, wherever situated, was much more likely to recur after operation in persons under 30 or 35 years of age than in persons over 50 years of age. In old persons by removing the enlarged lymphatic glands again and again the disease might sometimes be eradicated. Hence it was important after removal of the breast to examine the patient every two or three months so that any recurrent growth could be at once removed. The prognosis after operation in malignant disease of the breast depended not only upon the age of the patient but also upon the extent of the operation and upon the nature of the malignant growth. In cases of sarcoma and of duct cancer the prognosis was much better than in cases of scirrhus. Soft, rapidly-growing cancers were also more liable to recurrence. In cases of atrophic scirrhus possibly operation might do more harm than good. In order to preserve the movements of the arm and shoulder-joint it was recommended that the arm should be fastened by means of a bandage to the head of the bed for some days after the operation. In at least 20 per cent. of his cases there had been no recurrence within three years. Mr. Jessett had performed vaginal hysterectomy for uterine carcinoma in over 120 cases. Cases of malignant disease of the os uteri and lower part of the cervix were most favourable for operation. Eleven such patients operated upon between 1892 and 1896, in addition to others of later date, were alive and well. In the body of the uterus the prognosis was not so favourable. He expressed the opinion that many cases arise from malignant degeneration of a submucous fibroid tumour. Between 1891 and 1895 he had performed vaginal hysterectomy for cancer of the body of the uterus 16 times. Four of these patients were free from recurrence at periods varying from three to six years. The most unfavourable cases were those in which the disease commenced in the cervical canal, owing to the rapidity with which the disease extended to the surrounding parts and the uterus becoming fixed. Of the whole 120 cases only eight patients had died as a result of the operation. Of 70 cases operated upon prior to July, 1896, 15 patients were known to be alive and free from recurrence, whilst five others had died more than three years after operation from other diseases than cancer. The importance of early diagnosis of malignant disease, both in the breast and in the uterus, was dwelt upon. Mr. Jessett had in two cases followed the recommendation of Dr. Beatson that oöphorectomy should be performed in certain cases of inoperable cancer of the breast, but in neither case was the slightest benefit noticeable.—Mr. Stanmore Bishop protested against the dictum that those breast cases were least liable to recurrence in which suppuration occurred in the wound. Skin should be sacrificed freely, but it was always best to obtain primary union by gliding flaps or by Thiersch's grafts.—Mr. Milner mentioned two cases in one of which, four years after amputation of the breast for cancer, there were numerous deposits in the scar and in the axillary and supra-clavicular glands. No further operation was performed, but two years later most of these deposits had atrophied and some had disappeared. The patient had been last seen nine years after the operation. In the other case, one of fungating scirrhus of the breast, the tumour and the axillary glands weighed nearly 10 lb. There had been no recurrence four years after operation.—Dr. Helme argued against the opinion that in all cases of discharge from the senile uterus one should infer a malignant origin and should resort to hysterectomy.—Dr. Donald, Dr. Buckley, Dr. Walter, Mr. Platt, Mr. J. W. Smith, and Dr. Graham also took part in the discussion.

Midland Medical Society.—The seventh ordinary meeting of this society was held on March 1st at the Medical Institute, Birmingham, the President, Dr. W. G. Lowe, being in the chair.—Mr. Gamgee showed a case of Coxa Vara. The patient was a male, aged 16 years. The disease affected the left hip and had been noticed seven months. The chief symptom was pain about the hip on standing. The chief physical signs were—(*a*) three-quarters of an inch of shortening; (*b*) free flexion; (*c*) abduction very limited; (*d*) the trochanter above Nélaton's line; (*e*) muscular wasting; and (*f*) displacement of the trochanter outwards. A radiograph was exhibited showing the dropping and lengthening of the neck of the femur which characterised the disease.—Dr. Kauffmann showed a man, aged 53 years, the subject of Senile Chorea. The affection which was attributed by the patient to the carrying of excessively heavy weights (he was a market porter) had come on gradually, commencing two years before in the left hand. There was no nervous disorder in any near relative, several of whom were living. The patient appeared aged beyond his years. His reason was good, his speech was a little jerky, and his voice was feeble. There was no aphasia. The handwriting which the sufferer declared used to be very good was quite illegible, the marks bearing no recognisable resemblance to ordinary letters. The choreic movements affected the face, the respiratory muscles, and all four limbs and resembled in character those seen in juvenile chorea. They ceased only for short periods during sleep, being continued during the greater part of apparently sound sleep. Under observation the movements became markedly aggravated. The muscular weakness was such that the patient could not walk unsupported.—Dr. Short showed a case of Wasting of the Thenar and Interosseous Muscles of the left hand in a compositor. There was no history or sign of lead-poisoning. He had worked for six years with a compositor's "stick" in the left hand and six months ago the left hand was first noticed to be weak. There was some cramp in it at first but no tingling or numbness of the hand. The hand gradually wasted and when seen two months ago showed the reaction of degeneration. There had been no sensory symptoms throughout. Great improvement had taken place under treatment and now there was no reaction of degeneration. His hand was now fairly strong. In spite of the great improvement the prognosis in this case was still doubtful. It was shown as one of the cases referred to in Dr. Short's paper on the treatment of "Occupation Neuroses."—Mr. Jordan Lloyd showed specimens of Carotid and Aortic Aneurysms removed post mortem from the body of a man, 38 years of age. The man had a healthy history and had never suffered from venereal disease of any kind. Seven weeks before his death he had first observed a swelling in the right side of the neck at the level of the upper border of the larynx which had the ordinary characters of a carotid aneurysm. He was admitted into the Queen's Hospital for the purpose of ligation of the vessel. He was then in his usual health. During the night preceding the morning on which the operation was to have been performed he was suddenly taken with hæmoptysis—small in amount—became collapsed, and died within half-an-hour of the onset of the first symptoms. The necropsy showed death to have been due to a rupture of a moderate-sized aneurysm of the thoracic aorta situated about three inches beyond the arch and developed from the right side of the vessel over the front of the spine towards the right pleura. Rupture had taken place into this cavity. The lower lobe of the right lung was adherent to the wall of the aneurysm and at the site of this adhesion an escape of blood had taken place into the lung, giving rise to a large pulmonary apoplexy. The man had not complained of any symptom which directed attention specially to the chest, but the lungs and heart were examined in the ordinary manner and passed as healthy.—Dr. Walter Jordan read a paper on Spastic Paralysis in Childhood.—Dr. Short read a paper on Ten Cases of Occupation Neuroses.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A meeting of this society was held at 20, Hanover-square, W., on March 2nd, the President, Dr. R. Fortescue Fox (Strathpeffer Spa), being in the chair.—20 candidates were elected.—Dr. Douglas Kerr (Bath) read a paper on the Treatment of Disease by Heat. After mentioning that the Turkish bath was first introduced into England in 1860 he referred to box baths heated by lamps of various forms and described the Tallerman, Dowsing, and Greville apparatus. He pointed out that the principle underlying the treatment was expressed in the fact that cold applied to the body surface stimulates, while heat facilitates, function; he made a strong point of the use of whole body-bathing in hot air apparatus as against local appliances; he gave the facts of such high temperatures as are noted in textbooks and expressed the opinion that hot-air baths would prove a useful adjunct to thermal treatment but would not give such good results when employed alone. Dr. Kerr concluded by pointing out the peculiarity of the heat supplied by the Dowsing bath which was luminous and radiant, in this respect more closely resembling the sun's rays.—Dr. Hedley (London) read a paper entitled the Therapeutics of Heat. He first referred to the hygienic and curative uses of heat in ancient and modern times. He then discussed the merits and demerits of recent apparatus for the application of high temperatures to the body, giving marked preference to such as supplied heat from a luminous source, inasmuch as it had been proved by experiment that as light rays were added the heat rays became more intense. He then dwelt upon the *modus operandi* of heat in therapeutics, taking the instance of a simple sprain and those phases of the inflammatory process that were likely to be influenced by heat.—Dr. Whitby (Clifton) said that both dry and moist heat caused a measurable increase of the girth of the limbs and a decrease of the abdominal girth, the latter from depletion of the splanchnic vessels.—Dr. Luff (London) said that he had had excellent results from the employment of local superheated air-baths in selected cases of gout, rheumatism, and rheumatoid arthritis.—Dr. James Myrtle (Harrogate) said that the great and immediate relief of local pain so often seen was probably due to a soothing action on the peripheral nerves and on the vaso-motor system. He then illustrated the clinical value of the superheated air-bath by relating the history of several cases, in one of which a temperature of 392° F. had been attained.—Dr. Bowles (London) said that in the Dowsing bath it was claimed that the heat was radiant and produced different effects. Inasmuch as it had light as well as heat it was different, but the value of the effect of this light had not been in any way gauged. In his experiments in the Alps he found that light reflected from snow acted quite differently on the human tissues to direct sunlight and that the effects were entirely out of proportion to direct heat.—Dr. Hyde (Buxton) remarked that after several years' observations he discovered, especially in rheumatoid arthritis, that many of his apparent successes were not permanent. In many the pain and swelling remained reduced, but the joints afterwards became more fixed and crippled.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 21st, the President, Dr. J. B. Berry, being in the chair.—The following cases and specimens were shown:—Dr. March: A Case of Actinomycosis of the Upper Jaw.—Dr. J. H. Bell: A Case of Leucoplakia of the Tongue.—Dr. Bronner: Two Cases of Operation for Mastoid Disease.—Dr. Mitchell: A Specimen of Hydatidiform Mole.—Dr. Althorp showed specimens of (1) Sarcoma of the Sternum; and (2) an Ovarian Tumour removed by Operation.—Mr. Rawson showed a Foreign Body (wire with attached thread) removed from the Male Urethra.—Mr. Wilmot showed: (1) A Stomach showing Extensive Ulceration; (2) Cerebral Hæmorrhage in a girl, aged 19 years; and (3) Cardiac Thrombosis.—Dr. Campbell showed organs from a case of Lymphadenoma.—Dr. Rabagliati showed a Fibroma of the Uterus removed by operation.—Dr. Wood showed a Fibroma of the Uterus removed by operation.—Dr. Mitchell related a case of Recurrent Melanotic Sarcoma which he had treated by the application of formalin. The case was one in which a melanotic sarcoma of the cheek had been twice removed and had recurred. The recurrent growth was of the size of the first and was not deemed suitable for further operation. The skin over the growth had ulcerated and constant hæmorrhage was taking place. The hæmorrhage was not stopped by the use of ordinary styptics and the application of a strong solution of formalin was tried. This was completely successful in checking hæmorrhage, and not only so but it induced coagulation and dry necrosis of the tissues for a depth of about a quarter of an inch. This dried portion could be removed by the knife without any bleeding and thus it was possible to get away all the obvious growth piecemeal. The solution contained 20 per cent. of formic aldehyde and was applied by soaking a piece of cotton wool and covering this with gutta-percha to prevent evaporation. A good deal of pain was caused by the application which lasted for a considerable time; the pain was controlled by the administration of opiates. Some œdema of the eyelid and also of the neck was occasionally produced but caused no trouble. Dr. Mitchell suggested that the application of formalin might form a useful means of treatment in cases of tumour which for various reasons were not amenable to ordinary surgical treatment.—Dr. Bronner read a paper advocating the Use of Protargol as a Local Application in Diseases of the Eye and Throat in cases where nitrate of silver had been usually employed. Among the advantages he enumerated were its comparative painlessness in application and its non-staining property.—Mr. Horrocks read a paper on Gastroplication for Dilated Stomach.

HAMPSTEAD MEDICAL SOCIETY.—A meeting of this society was held on Feb. 14th at 167, West-end-lane, at the invitation of Mr. Hardwicke.—Mr. A. H. Tubby gave a lecture on the Diagnosis and Treatment of Sprains and on some Fractures. After referring to the difficulty of diagnosis of sprains and to the use of the x rays in excluding fractures he defined a sprain as a momentary alteration in the relation of bones with injury to the surrounding tissues, described the structures comprising a joint, and enumerated the following as the symptoms of sprains. 1. Pain of short duration due to the stretching of ligaments and soft tissues. 2. A quiescent stage of from two to three hours' duration during which effusion of blood and lymph took place. 3. Pain of long duration due to pressure by effusion on terminal nerves. 4. Extravasation of blood. It was important to watch the site of this as it gave a fair indication as to the ligaments injured and the future direction of passive movement later. 6. Tender spots which were usually found in the following situations: (*a*) in sprain of the knee at the internal tuberosity of the tibia; (*b*) in sprain of the ankle at the top of each malleolus; and (*c*) in sprain of the elbow about one inch below the external condyle. The following treatment was recommended:—First stage: Place the joint in such a position as to ensure the smallest potential cavity. Immobilise. Apply firm pressure by means of wool and bandage. Use an ice-bag or evaporating lotion. Maintain this until the third stage is reached. Then, employ gentle massage and heat to aid resolution. If the tender spots persisted iodine and blistering should be resorted to. In a child when a sprain does not clear up in six weeks tuberculous disease should be suspected and the parts should be rigidly immobilised. Mr. Tubby then passed on to consider "some fractures," remarking that of all these injuries those in the neighbourhood of the elbow were the most difficult to diagnose. He propounded this axiom which he had learnt from Mr. Robert Jones. In all cases of acute or doubtful injury at the elbow-joint, excluding fracture of the olecranon, extend, supinate, flex fully, and fix in this position. Avoid splints and bandage the arm to the chest and the hand to the opposite shoulder. This treatment was suitable for fracture of the condyles, coronoid process, or transverse fracture of the lower end of the humerus. Reference was then made to subluxation of the radius and separation of the epiphyses in children. Pott's fracture was briefly touched on, the necessity of over-inversion being urged in every case. The splints advocated were plaster of Paris (Croft's) and malleable iron.—A discussion followed.

Nottingham Medico-Chirurgical Society.—A meeting of this society was held on March 1st, Mr. T. Davies Pryce, President, being in the chair.—Dr. J. W. Noble read a paper on Joint Affections in Locomotor Ataxia, describing an interesting case which had been under his care for the past two years. The patient, a woman, aged 39 years, with a history of syphilis, had been ataxic in her walking for less than a year before the onset of the swelling in her right knee. The effusion reached its maximum size in three or four days and by the end of three weeks there was much deposit of bone salts. The bony growth had since been gradually absorbed, giving rise to an outward and upward dislocation of the tibia on the femur, the outer condyle of the femur and the inner tuberosity of the tibia having disappeared. The morbid anatomy of the joint was described, also that of the spinal cord, and the theories as to the causation of the joints being so suddenly and apparently capriciously affected were discussed. Contrasting the tabetic affection of the joint with rheumatoid arthritis the differences were chiefly (1) the sudden onset; (2) the comparative painlessness; (3) the size of the joint affected; and (4) the affection of one joint only as a rule, the foregoing being characteristics of the tabetic joint affection.—Mr. Laws showed a patient suffering from Ophthalmoplegia Interna. He considered that this case supported the view that the paralysis was due to an affection of the bulb.—Mr. R. C. Chicken showed a case of Compound Depressed Fracture of the Skull produced by a Kick from a Horse. The patient was a child aged six years. He had been trephined three times in all, once soon after the accident and twice subsequently for paralysis which remained. When shown he was perfectly well. Mr. Chicken also showed a Small Foreign Body which had lodged in the bronchus of a child producing intense dyspnœa and lividity, with coughing and other urgent symptoms. It remained in the bronchus for a day or two and was then coughed up. It proved to be a piece of walnut.—Mr. J. G. Willis showed a Cystic Adenoma of the Thyroid which he had removed by operation from the patient whom he had shown at the previous meeting. The incision for the removal had been made down the anterior border of the sterno-mastoid and when the capsule had been defined enucleation was not attended with any great difficulty.

West London Medico-Chirurgical Society.—A clinical meeting of this society was held at the West London Hospital on March 3rd, Dr. S. D. Clippingdale, President, being in the chair.—Dr. Andrew Elliot showed a case of well-marked Locomotor Ataxy in a Woman.—Mr. William John spoke.—Mr. McAdam Eccles showed (for Dr. G. P. Shuter) a Survivor of the Faversham Detonator Explosion. She had lost her sight and had suffered amputation of the left forearm.—The President showed a young woman who exhibited a Want of Development of the Left Forearm and Hand.—Mr. Rowland Pollock showed two brothers with Multiple Want of Development of the Hands and Feet.—Mr. McAdam Eccles showed a man with Marked Want of Growth of the Right Upper Limb.—These cases of deformity were admirably demonstrated on the fluorescent screen by Dr. H. Low and were discussed by Dr. H. P. Potter, Dr. E. P. Paton, Dr. P. Abraham, Mr. F. Savery, Mr. W. E. C. Musson, and Mr. Vaughan Pendred.—Mr. Brindley James showed a young man with a Deep Sulcus above and behind the Upper Part of the Manubrium Sterni.—Mr. McAdam Eccles and Dr. E. P. Paton made a few remarks.—Dr. Andrew Elliot showed (for Dr. Seymour Taylor) a man who presented many of the Symptoms of Myxœdema.—Mr. McAdam Eccles exhibited a man with a Marked Nævoid Condition of the Penis and Scrotum.—Mr. Vaughan Pendred showed: (1) A girl, aged 19 years, who had marked symptoms of what appeared to be Pseudo-hypertrophic Paralysis; and (2) a case of possibly Early Acromegaly.—The cases were discussed by Dr. Arthur Haydon.

Æsculapian Society of London.—A meeting of this society was held on March 3rd, the President, Mr. D. H. Goodsall, being in the chair.—Mr. W. Campbell M'Donnell showed a photograph, sketch, and microscopic specimen of a Multiple Diffuse Myoma from a multipara, aged 37 years, an alcoholic, who died from septicæmia. The attendant had tried for an hour to remove the placenta by the hand in utero but only partly succeeded. Hyperpyrexia followed on the third morning when a handful of placenta was removed. Under ether further attempts were made to remove what seemed to be adherent fibrosed fragments, some of which were removed by the blunt curette. A later attempt was made on the fifth day. The patient died from cardiac failure 12 hours after the operation. From the first the pulse was bad, being 130 per minute, with a temperature of 99° F. The uterus was covered for the greater part of its body with bossy and pedunculated masses which were growing in the cornual angles and were, as proved by the microscope, of myomatous structure. The upper third of the endometrium was gangrenous and the broad ligaments were intensely inflamed. The lymphatics of the myoma were crowded with micrococci and there was no reactionary inflammation there.—Dr. B. G. Morison read notes of a case of Rectal Impaction of Tiger Nuts in a boy, aged 11 years, who was anæsthetised on account of the impracticability of removing the mass by the finger or spoon. Then ovum forceps removed a soap-dishful of undigested nuts. On the third day he passed a "concrete-like motion" after an enema and did well.

Reviews and Notices of Books.

A Manual of Diseases of the Nervous System. By Sir William Gowers, M.D., F.R.C.P. Lond., F.R.S. Third edition. Edited by Sir William Gowers and James Taylor, M.A., M.D.Edin., F.R.C.P. Lond. Volume I., Diseases of the Nerves and Spinal Cord. London: J. & A. Churchill. 1899. Price 15s.

We welcome the appearance of the first volume of a new edition of Sir William Gowers's great work which is certain to be the standard authority on diseases of the nervous system for many years to come. In reviewing former editions we have spoken fully of the completeness of its scope, the wealth of clinical and pathological information in every page, of the soundness of its teaching, and of the remarkable clearness and aptness of the diction employed, and in the present edition we can speak in even stronger terms in praise of its excellence. The book throughout bears evidence of the most careful revision. The account of the structure and functions of the spinal cord has been re-written so as to incorporate the results of the researches of Golgi, Ramon y Cajal, and others. Sir William Gowers himself contributed so powerfully to the establishment of the new doctrines in his work, "The Dynamics of Life," that his riper views will be read with interest. The nerve cell is dethroned from its position as the all-important element in the cord and in its place we find the "neuron"—i.e., the cell plus its axis cylinder and its short processes with their branching terminations. The adoption has involved alterations in speaking of the pathology of most of the organic diseases of the spinal cord and it will still more profoundly affect the teaching as to the pathology of the diseases of the brain.

There is an admirable chapter on the value of various symptoms in indicating the locality and extent of spinal lesions and the usefulness of the section has been increased by a reproduction of the diagrams showing the sensory root areas as described by Dr. Henry Head.

A very clear account of the present state of our knowledge with regard to the "muscle spindles"—the sensory organs of muscle—is given as an appendix by Dr. F. E. Batten.

Of the new matter the most important is the section on Sclerosis from Toxic Blood States on which Dr. Taylor has previously published instructive papers. The form known as pellagra, supposed to be due to some fungus or micro-organism growing on maize, and the sclerosis associated with anæmia and other blood states are well described and illustrated by micro-photographs of characteristic sections.

There are a few changes in nomenclature. "Infantile Paralysis" and "Progressive Muscular Atrophy" are displaced by "Acute Atrophic Paralysis" and "Chronic Muscular Atrophy."

A number of new illustrations are scattered through the book and we are glad to see that it is printed on better paper than that used for previous editions. We would point out, however, that some of the blocks show signs of wear and the resulting prints are not quite worthy of so important a book and in the second volume we have *no doubt that* this point will not escape attention.

Sir William Gowers's book is already an accepted classic on neurology and one of which he and the profession in England may well be proud, since it is a standard text-book in other countries besides our own, and we heartily congratulate Sir William Gowers and Dr. James Taylor on the appearance of this new edition which will not merely sustain the very high reputation which the manual enjoys but will enhance it.

The Anatomy of Labour as Studied in Frozen Sections. By A. H. F. BARBOUR, M.D., F.R.S. Edin. Second edition. Post 8vo. Edinburgh: W. & A. K. Johnston. 1899.

IN the second edition of his book Dr. Barbour has added the results obtained from the study of the 25 frozen sections illustrating the anatomy of labour published during the last 10 years. As the new facts simply support and supplement the conclusions already arrived at he has not re-written the whole book but embodied them in a new chapter. It is interesting to note how fully the new facts do corroborate the conclusions of Dr. Barbour and the other workers in this field of anatomy, and although the time has not yet arrived when the history of labour can be constructed from a series of frozen sections, yet our knowledge upon various details is much fuller than it was and is in some respects almost complete. Valuable assistance has been derived in the study of the more recent sections by the use of casts for determining the forms and relations of cavities and masses.

We may briefly call attention to some of the more important points brought out by a study of the 38 sections which are now available for the student. An examination of the relations of the peritoneum shows that while anteriorly there is a tendency to its elevation during the first stage of labour and still more so during the second stage, posteriorly the level of the pouch of Douglas does not tend to be affected by labour. The fact that the level of the fundus of the uterus is the same, or even relatively higher, in the second stage than in the first stage is confirmed by Dr. Barbour's section of a case towards the end of the second stage of labour. Casts of the form of the uterus during pregnancy and labour show that while the pregnant uterus moulds itself upon the spinal column and pelvis, the uterus during the second stage moulds itself upon the child.

Von Franqué's researches upon the relations of the lower uterine segment and the cervix, taken together with the recent sections, may be regarded as settling once and for all the celebrated discussion as to the exact limits of the cervix and undoubtedly show that no portion of that canal takes part in the formation of the uterine cavity. The elongation of the body of the fœtus during the second stage by the straightening of its spinal column is well shown by the attitude of the fœtus from a case towards the end of the second stage of labour. A very interesting point now clearly brought out is that the lower part of the anterior uterine wall is thinner than the rest before labour begins; this thinning is increased during labour. A corresponding part develops posteriorly. There is therefore in a normal labour a separation of the uterine wall into two parts at the retraction ring. In all the sections published except one the chin of the child is flexed on the sternum before the commencement of labour and during the second stage until the head is born. The one exception is Pinard and Varnier's case of occipito-posterior presentation. It becomes a question, therefore, whether we are justified in speaking of flexion as a movement of labour at all. An interesting confirmation of the view that simple diminution of the placental site is not sufficient to cause separation of the placenta is shown by Pestalozza's section with twin placentæ, where there is no separation, and Pinard and Varnier's case of triplets, where the separation has occurred only at the lower margin of the larger placental mass. The membranes are shown to be completely separated during the second stage of labour up to the retraction ring but not above it. Webster's sections from the puerperium bring out two new points: that the uterus after delivery sinks into the pelvis and compresses the veins of the broad ligament and so lessens the bleeding and that the uterus is not diminished in size during the first three to four days of the puerperium.

The study of the anatomy of labour is a very absorbing one and we can cordially recommend the second edition of this book, written as it is by one of the chief authorities, to all those who desire to keep their knowledge of the subject up to date. The book is illustrated by a number of figures and of plates of the more important sections published.

Albuminuria and Bright's Disease. By NESTOR TIRARD, M.D., F.R.C.P. Lond. London: Smith, Elder, and Co. 1899. Pp. 362. 15 Illustrations. *Price 12s. 6d.*

THE appearance of a new work on renal disease cannot fail to excite interest and curiosity as to its contents among medical readers, inasmuch as although a great deal of research has been carried on both at home and abroad no special and critical treatise has appeared on the subject in England for a number of years. Of the two subjects in this volume that of Albuminuria is undoubtedly the better treated. Dr. Tirard divides albuminuria into (1) extra-renal, such as that due to pyelitis or cystitis, and (2) renal or true. The latter is further considered in two groups, of which one includes albuminuria due to definite structural changes in the kidney, while the other contains functional or cyclic albuminuria; hæmatogenous albuminuria due to toxic, dietetic, and febrile causes; and albuminuria due to mechanical factors such as venous engorgement. The prognosis on the various functional forms of albuminuria is definitely stated to be good provided that there is no doubt about the diagnosis; this is especially true, as proved by the author's experience, with regard to dietetic albuminuria.

Special chapters are devoted to Acute Nephritis and to Scarlatinal Nephritis. Under the heading Chronic Nephritis the large white and the contracting white kidney are considered together, and this is convenient, as clinically no hard-and-fast distinction can be drawn between them. The term "cirrhosis of the kidney" is one which, to our mind, has no advantage over the ordinary name "granular kidney"; it is of course used as being the equivalent of fibrosis, but since this is a secondary meaning, it would have been preferable to have avoided a title which, though often suitable to a fibrotic liver, has no special use when applied to the arterio-sclerotic kidney. It is somewhat disappointing not to find more said about the relation of arterio-sclerosis to the kidney changes in the chapter devoted to Cirrhosis of the Kidney. Puerperal nephritis and eclampsia have been made the subject of a useful essay which contains a great deal of valuable information. In the chapter on the retinal changes in Bright's disease there are some admirable coloured plates from originals by Mr. Stanford Morton, while elsewhere there are excellent microscopic drawings of the morbid changes in the kidney which add considerably to the value of the text. The descriptions of the symptoms and treatment of the various forms of Bright's disease are clear and essentially practical. In conclusion we may say that while this work shows no great originality, and cannot be said to add largely to our knowledge, it is thoroughly sound and well considered and is written in a pleasing and graceful style.

LIBRARY TABLE.

Physician's Book for Private Formulæ. Bristol: John Wright and Co.—This is a useful little waistcoat-pocket book with blank leaves labelled alphabetically after the manner of a "Where is it." At the end are a posological table of the 1898 British Pharmacopœia (in which the strength of the preparations for internal use might with advantage be entered), the English and metric weight and measure systems, and a short account of the treatment of poisoning. It is a nicely bound book of convenient size, well adapted for the purpose for which it is intended.

The Purification of Sewage. By SIDNEY BARWISE, M.D. Lond., M.R.C.S. Eng, D.P.H. London: Crosby Lockwood and Son. 1899. Pp. 150. Price 5*s.*—The question of the best method of the purification of sewage has been placed *sub judice* from the fact that a Royal Commission of inquiry is making a practical investigation into the matter. Dr. Barwise's little book is a useful contribution to the subject and sums up clearly the methods now in vogue and the direction in which recent research has seemed to dictate that we should go in order to solve a problem which has long been the *bête noire* of the sanitary engineer. We welcome the publication of this volume because it contains the views of a writer who is competent to judge and who, moreover, is a disinterested person except so far as the attainment of the most sanitary and economic method of dealing with sewage is concerned. The number of books published on the subject during the last decade has been large, but the majority of them have been written by persons interested in specific processes. Dr Barwise has gleaned considerable experience on the question of the purification of sewage in the discharge of his duties as the medical officer of health to the Derbyshire County Council. The book records this experience and the author's opinions of the methods thus encountered. It may be said to contain all that need be known on the subject, being unencumbered by lengthy descriptions of a thousand and one chemical methods which now are known to be both unscientific and extravagant. The last chapter is very much to the point in helping to decide what process of purification to adopt under various circumstances of environment. The descriptions are perfectly simple and lucid and a perusal of the short chapters should save the reader who would be acquainted with the recent developments of the subject much time that would otherwise be lost in a useless study of the enormous number of methods of treatment which now belong to the past.

Year-book of Pharmacy, 1898. London: J. & A. Churchill. Pp. 536. Price 10*s.*—This book is a welcome publication because it is usually admirably compiled and gives an excellent review of the work done every year relating to pharmacy, materia medica, and chemistry. Last year the meeting of the British Pharmaceutical Conference was held at Belfast and many important and interesting papers were read and discussed, the proceedings being published at the end of the volume. The year-book represents a considerable amount of work and the committee of publication are to be congratulated on the product. The book really amounts to an annual bibliography of the additions to our knowledge on the wide subjects indicated.

The Girl's Own Paper.—The March part of this magazi contains the thousandth number, with which is issued a supplement a "portrait gallery" of contributors, includi portraits of members of royal families and men and wome eminent in literature and science.

The Leisure Hour.—In the March issue of this magazi there is an interesting article on a Visit to Lourdes, and well-executed reproduction of Mr. W. Q. Orchardson "Her Mother's Voice."

JOURNALS.

The Journal of Physiology. Edited by M. FOSTER, F.R.S and J. N. LANGLEY, F.R.S. Vol. xxiii., No. 6. London J. Clay and Son. 1899. 27 Figures. Price 5*s.*—This numb contains four articles and concludes with the proceeding of the Physiological Society. The first article, whic occupies the greater part of the number, is by Dr. J. Ros Bradford on the Results following Partial Nephrectomy This operation, even when two-thirds of the total weight o the kidney have been removed, need not be followed b death, but when more than this is ablated death follow from asthenia. The removal of approximately two thirds of the total weight of the kidney is followed by very great increase in the amount of urinary wate and also by an increase in the amount of ure excreted and the fragment of kidney left is able t excrete amounts of urea far larger than those usuall excreted. The nitrogenous extractives of the tissues are increased. The blood-pressure remains high. The second article is by Dr. W. P. Herringham, who contributes a short article on the Quantitative Analysis of Potassium and Sodium in Urine. The third article is by Dr. William Bain and Dr. Wilfrid Edgecombe on the Physiological Action of Certain Mineral Waters and Baths on the Blood and on the Excretion of Urea and Uric Acid, with a note on the Quantitative Relationship between Uric Acid and Leucocytes. The last paper is by Dr. Archibald Garrod and is devoted to Alkaptonuria, a Simple Method for the Extraction of Homogentisinic Acid from the Urine.

The Journal of Physiology. Vol. xxiii. Supplement. An Account of the Proceedings of the Fourth International Physiological Congress held at Cambridge, England, August 23rd to 26th, 1898. Issued by the Physiological Society of Great Britain and edited by LEONARD HILL, M.B. Lond. Cambridge: at the University Press. 1899. Pp. 74. Figs. 27. Price 6*s.*—In this supplementary number of the *Journal of Physiology* Dr. Leonard Hill has given a *résumé* of each of the 92 communications which were received and read at the Cambridge Congress and of the several exhibits which were made. Amongst the more important of the papers read were those of Mr. E. J. Marey advocating the formation of an international commission for the unification and control of physiological recording instruments. Physiological investigations and researches, it is hoped, will thus be rendered more precise and more easily comparable *inter se.* M. Demoor from his researches on cerebral neurones concludes that the nervous elements are plastic but do not present amœboid movements and from his researches on the brain of a dog holds that in this animal there are two kinds of cortical centres—viz., centres of projection and centres of association. The parietal centre of association is highly developed, that of the frontal region is poorly developed. The observations of *Dr. Heger* show that the neurones of the cortex of the brain of many different animals present noticeable difference according to whether they have or have not been excited before death. Several communications are made bearing on the circulation, as that of Dr. Leonard Hill on the influence of gravity on the circulation, showing that whilst in eels and the grass snake in which the cerebrum had been destroyed by pithing the blood gravitates away from the heart on raising them to the vertical position, in the wild rabbit, cat, dog, monkey, and man the power to resist the influence of gravity is very perfectly developed. Dr. W. T. Porter of Boston describes the beat of the isolated mammalian ventricle fed on blood serum alone and showed that even isolated portions of the mammalian ventricle supplied through their nutrient arteries with a small quantity of serum at very low pressure will maintain rhythmical, long-continued, forceful contractions when surrounded by oxygen at high tension. Dr. A. Waller describes the influence of salts upon the electro-mobility of medullated nerve, and states that he found that in the action upon nerve of a salt BA the predominant moiety is B (the basic or electro-positive element)—e.g., any potassium salt is more effective than any sodium salt. Dr. E. Wertheimer and Dr. Lepage give the results of their experiments in exciting the accelerator nerves of the heart and observing the effects of such excitation upon the respiration. Several of the papers read bear testimony to the interest which is taken in physiological chemistry. Thus Mr. A. B. Macmillan of Toronto describes a method for the detection and localisation of Phosphorus in the Tissue Elements; Mr. F. H. Scott gives an account of some points in the Micro-chemistry of Nerve Cells; M. Delezenne gives an account of the Anti-coagulating Substance contained in Peptonised Blood; Dr. S. Fränkel of Vienna gives an account of the Chemistry of Albumin; and Dr. Martin Hahn of Munich deals with the Chemical and Immunising Properties of Plasmine. Another group of papers discusses gland extracts and their action—as, for example, that of M. Livon of Marseilles on the Action of the Extract of the Pituitary Body on the Vagus and of the Extracts of the Adrenals, Spleen, Pancreas, and Thymus on the Blood-pressure, and that of M. G. Moussu of Alfort on the Functions of the Thyroid and Parathyroid Bodies. Several instruments were exhibited at the Congress intended to promote physiological research, such as the sphygmometers of Leonard Hill and Harold Barnard, the autographic balance of J. Fano, the sound or toninductorium of M. H. Kronecker, and the apparatus for demonstrating the movements of the eyeball by Mr. H. P. Bowditch. The editing of the number reflects great credit on Dr. Leonard Hill.

Annales de Gynécologie. February, 1899.—This number contains the following articles: The Gynæcological Instruments of Professor Auguste Reverdin, by Dr. Charles Berthier; a continuation of his paper upon Bacteriological Researches in the Genital Tract of the Female by M. J. Hallé; the Effect of Ligature of the Uterine Arteries upon Hæmorrhages from the Uterus, by Dr. Mangin; a case of Glandular Hypertrophy of the Cervix Uteri of Benign Character simulating a Malignant Tumour, by Dr. de Sinéty; Vagino-abdominal Hysterectomy by Dr. Delagénière; and the usual bibliography.

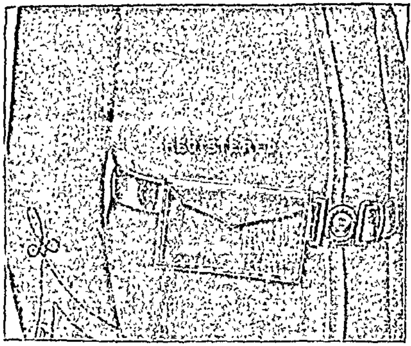
VACCINATION IN TROWBRIDGE UNION.—The returns show that out of 280 births in Trowbridge in 1897 only 16 infants were successfully vaccinated, 97 being unaccounted for, and exemption certificates making up the remainder. In the first half year of 1898 there were 132 births, and of these five infants were vaccinated. In Melksham, of 150 infants born, 29 were vaccinated in 1897, and during the first six months of 1898 only 11 were vaccinated out of 72. At the last meeting of the Wiltshire Standing Joint Committee recently held at Trowbridge the chief constable asked for instructions as to the vaccination of members of the police force. A letter was read from Sir Charles Hobhouse in which he stated that he objected to vaccination being made compulsory in the present state of the law. He suggested that the following question should be put to candidates for the force: "Are you willing to be vaccinated or revaccinated if the police surgeon considers it necessary?" After some discussion a resolution embodying this suggestion was carried unanimously.

New Inventions.

THE MALE NURSE'S WALLET.

"FOR a considerable time," writes Mr. J. H. Parker Wilson, medical officer of Her Majesty's prison at Pentonville, "I have been impressed by the fact that no proper wallet has been placed upon the market for the use of the male nurses in our public institutions, while the wallet which I have devised to meet this want would also, in my opinion be of use to the nurses of our naval and military medica service.

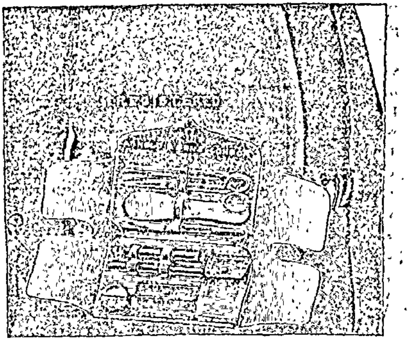
FIG. 1.



The wallet shut.

"The wallet is so constructed, as will be seen by the above illustrations, that it can be adjusted to any belt by means of two loops. It cannot, therefore, be mislaid or forgotten. The contents are as follows: probe, director, spatula, dressing forceps, scissors with blunt points, tape measure, thermometer, pencil case, and pouches for pins, litmus paper, &c."

FIG. 2.



The wallet open.

These contents constitute, in our opinion, all the things most necessary to a nurse in the performance of his or her duties, so that we anticipate for Mr. Wilson's useful little wallet ready acceptance by the persons for whose benefit it has been designed. The makers of the wallet are Messrs, Arnold and Sons, West Smithfield.

THE LANCET.

LONDON: SATURDAY, MARCH 11, 1899.

As we intimated in our issue of March 4th the Executive Committee of the General Medical Council met on Monday, Feb. 27th. The published minutes of the Committee give us an insight into the business which occupied the attention of the Committee and is likely more or less to claim the attention of the Council in May. The mere enumeration of the subjects of the Committee's business will show that there is much to excite the interest of members of the profession. The principal questions dealt with were certain memorials on the issue of certificates of proficiency in departments of medicine, surgery, or midwifery; the risks of the employment of unqualified dispensers by registered practitioners; the creation of bacteriological laboratories; inquiries by the Italian Ambassador at the Court of St. James's as to the regulations which in England govern obstetric aid by midwives and the regulations under which Italian practitioners may practise in England; the law in England as to professional secrecy affecting the medical profession; public instruction in England in the subject of vaccination; restoration of names to the Register and the identification of the applicant; the inspection of documents; the President's report relative to increased penal and disciplinary powers; and the case of ROWLAND, the man who personated a registered practitioner named NUGENT, and who is now in prison.

The minutes of the Executive Committee show, as previous minutes have shown, the tendency of certain persons or sections of the public to appeal to the Privy Council to initiate what they consider to be improvements in medical practice or in the laws by which it is regulated. The Privy Council with much promptitude refers such memorials to the General Medical Council. Few things interest the general practitioner more than the employment of assistants for dispensing medicines. The competence of the person so employed has been left hitherto to the discretion of the medical practitioner. The occurrence of a recent fatal case in which by gross ignorance and carelessness on the part of an unqualified assistant a huge dose of morphine was dispensed has led one or two dispensing chemists to memorialise the Privy Council in favour of such a change in the law as will compel practitioners to employ only assistants who have a qualification for their work from some recognised body, such as the Pharmaceutical Society of Great Britain or the London Society of Apothecaries. The Executive Committee referred this subject to the consideration of the General Medical Council, but in the meantime expressed to the Privy Council the opinion that, whilst fearing the sad occurrence of occasional accidents from the employment of careless or incompetent dispensers, such cases are very rare and that probably the best protection is afforded to the public by the responsibility of the practitioner. It cannot be denied that the surgery of the general practitioner is a good school for learning the art of dispensing and that since pupilage to a practitioner has ceased to be obligatory the facilities for learning dispensing have become less. Practitioners will do well to take note that the competence of their dispensers is sure to engage the attention of the General Medical Council and would be well advised to do what is necessary to eliminate the risk of accidents.

The Executive Committee had before it other communications from departments of the Government. One of these was a communication from Sir EDMUND MONSON to Lord SALISBURY transmitting a Bill recently laid before the Chamber of Deputies by a private member for the establishment in every Department in France of laboratories for the conduct of bacteriological researches with a view to the prevention of disease in general and tuberculosis in particular. The Committee expressed approval of the proposed law and of the foundation of similar laboratories in this country. The Executive Committee wisely referred this communication to the meeting of the General Medical Council in May as well as the note from the Italian Ambassador asking for information as to the conditions under which Italian physicians can practise in Great Britain, and in the meantime directed the registrar to inform the Privy Council that the Committee would welcome a recognition of a right by English practitioners to practise in Italy which would enable *Her Majesty in Council*, under the provisions of Section XVII. of the Medical Act of 1886, to extend similar privileges to Italian practitioners in this country.

The question of the inspection of documents was also before the Executive Committee for consideration and report and the members seem to have arrived at a very sensible and short solution of it, meeting the two requirements which every sensible person recognises—first, the safe care of the documents, and, secondly, the right of every member of the Council to see all its documents. The Committee resolved to recommend to the Council that the Standing Order should run as follows:—

"That all documents of the Medical Council, when not required for use by its legal advisers, be available for inspection by any member of the Council on the following conditions: 1. That a notice in writing of three clear days be given to the Registrar. 2. That the subject of the documents needed for inspection be stated. 3. That the Registrar be held responsible for the safe custody of all documents. 4. That it be an instruction to the Registrar to have the documents so arranged with respect to chronological order and otherwise as to facilitate their inspection. 5. That no documents be removed from the premises of the Council. 6. That all such documents and the information therefrom derived shall be regarded as strictly confidential."

The Executive Committee in these suggestions has clearly expressed the feeling of the Council and of the profession that no impediment should be placed in the way of the study of its documents by members of the Council other than is necessary for their orderly and safe preservation.

We have only space to notice briefly a few other subjects which occupied the time of the Committee. The minutes of the Committee contain a long memorandum drawn up at the request of the President by Mr. MUIR MACKENZIE on "The Law of the Obligation of Medical Practitioners with Regard to Professional Secrecy." This memorandum, or rather the information which it contains, was requested by the Russian Ambassador in London for the use of his Government. The request was addressed by the Ambassador to the Home Secretary and was transmitted by the latter to the General Medical Council. On the subject of granting illegal certificates of proficiency in medicine, surgery, or midwifery the Committee came to the conclusion that as a Midwives Bill is now before Parliament there was no necessity for any immediate action. The important subject of the President's report relative to increased penal and disciplinary powers came up for discussion when it was plain that there is still much objection on the part of the qualifying bodies to be overcome. The Committee has referred the answers of these bodies to Mr. MUIR MACKENZIE for consideration and report at a future meeting.

THE Report of the Departmental Committee on Prison Dietaries which has just been published is a clear and concise exposition on the subject of prison dietetics. The whole report affords evidence that the question has been thoroughly investigated and that the opinions therein expressed are the result of careful study and mature deliberation. It is a moot point whether the new scheme of dietary which the committee have formulated will meet with general approval, but there can be no doubt whatever that the proposed changes constitute a much-needed improvement on the existing order of things. For our own part, we have never regarded the present system of local prison dietary as satisfactory. Some 20 years ago, shortly after the existing diets were introduced, THE LANCET had occasion to criticise the composition of the various diets and we more expressly pointed out what we regarded as a grave deficiency in the amount of fatty matter contained in the diets. The opinion which we then held has been amply confirmed by the report of the Departmental Committee for, in alluding to the new intermediate dietary, they state—"Such are the changes we have felt constrained to make with the view of improving the intermediate dietary, the principal net result of which will be a decided increase in the fatty elements which are so necessary in a prison dietary." The guiding principles which seem to have animated the committee in the course of their labours may be regarded as eminently sound and sensible. They *apparently started* with the view that every prisoner should receive the amount of food sufficient to maintain his general health and bodily condition so that on discharge he might be capable of taking up any honest means of livelihood. Having been told in their letter of reference that the main *principle* to be kept in view was that the ordinary prison diet was not to be regarded as an instrument of punishment, they proceeded to eliminate from the new dietary scale the penal element which undoubtedly is a feature of the lower classes of the existing local prison dietary. At the same time they were alive to the grave dangers which might accrue should the lowest of the proposed diets prove an attraction for the loafer or mendicant, and they so framed that scale (Class A) "that it shall consist of the plainest food, unattractive but good and wholesome, and adequate in amount and kind to maintain health and strength for the single week during which it would be given." On more general grounds they took into consideration the fact that the standard of living amongst the outside population has manifestly improved since the introduction of the present dietary; that during the two decades that have elapsed a marked change for the better has taken place in the general conditions of prison life apart from the dietary; and that an improvement has occurred in workhouse dietaries and in those of pauper lunatics located in county and borough asylums. On these premisses coupled with the tenour of the evidence at their disposal, both official and general, they came to the conclusion that some improvement of prison dietaries was necessary.

Before entering upon a critical analysis of the existing diets and before submitting their proposals regarding the constructive changes which they deem necessary, the committee proceed to criticise in no halting manner the present method of application of the local prison dietary which, on their showing, appears complicated and cumbersome in the extreme. The alterations which they suggest simplify matters greatly and must assuredly tend to facility of administration. The principle of variation of diet with length of sentence they have retained, although in a modified form. They have recommended the almost entire abolition of the system of progressive dietary whereby a prisoner is compelled to graduate through the lower diet immediately preceding that proper to his class. The progressive system is regarded as faulty and to have resulted in loss of weight. They have done away with the distinction between hard-labour diets and non-hard-labour diets in local prisons, which under present conditions seems to be a distinction without a difference, for it appears that a very large proportion of men sentenced to hard labour are exempted from performing the hardest tasks of prison labour by reason of physical defect, age, or infirmity, yet by virtue of the terms of their sentence they receive hard labour diet. Their lot, therefore, compares very favourably with that of men sentenced to imprisonment without hard labour who are presumably guilty of less heinous offences and who are practically placed at the same labour on a lower diet. The question is satisfactorily solved by according to men, women, and juveniles respectively a different diet, the diet for men being larger in quantity than the diet for women and the diet for juveniles being somewhat varied by the addition of certain aliments suited to their constitutional requirements. In discussing the dietary for juveniles the committee make some pertinent remarks on the subject of juvenile criminality which are well worthy of quotation. They state: "We have taken particular interest in the diet of juveniles. Witness after witness advocated the inclusion of milk in their dietary and we agree in the suggestion. The tendency of present day prison administration is to treat the youthful criminal in a reformatory rather than in a punitive sense. We are convinced that a large amount of criminality is due to physical and mental degeneracy, and a regimen designed to insure the physical and mental well-being of the youthful delinquent will prove better for the individual and in the long run better for the race. Nothing is more adapted to attain this desired end than a liberal dietary combined with physical exercise." This goes to the root of the whole matter; to those who are conversant with the criminal population, the poor physique, the stunted growth, the deformities, disablements, and disease, inherited or acquired, and due to drink, syphilis, scrofula, rickets, &c., must be visibly apparent. In framing the new scales of dietary the committee sought to arrange that the nutritive value of the food for each class of prisoner, both convict and local, should be fairly equivalent to the standards which experience and scientific considerations have indicated as sufficient for each class collectively; they adopted as a suitable standard for comparison the formula laid down by KÖNIG, a recognised authority on the subject of dietaries, as the minimum daily need of food-stuffs for individuals of both sexes and of various ages performing an average day's work. They aimed at evolving round the standard laid down by KÖNIG a series of diets suited to the varying circumstances of the whole prison population.

The existing and proposed dietaries are compared much to the disadvantage of the former. Class I. and Class II. diets were both found inadequate and unsparingly condemned. This is not to be wondered at seeing that physiologically considered they are about equal in nutritive value to the subsistence and rest diets of the authorities as laid down in the standard works on dietetics. Men cannot be expected to perform hard labour and maintain their weight and condition on diets possessing such low nutritive properties. In Class I. diet what has been termed the "sacred stirabout" will be unknown henceforth in English prisons. The investigations of the committee showed conclusively that a large proportion of prisoners lost weight on Class II. diet which is given for one month. They therefore suggested that a new and better diet (Class B) corresponding closely to the present Class III. diet should early be brought into operation in place of the existing Class II., that the duration of its application should be limited to three months, and, further, that a diet (Class C) corresponding to the present Class IV. should be provided for prisoners undergoing longer sentences. The nutritive properties of the new dietary are superior to those of the dietary at present in force; the amount of nitrogenous and fatty matters shows a decided increase everywhere. There is also an increase in carbo-hydrates except in the highest diet (Class C), but this cannot be regarded as a defect as the carbonaceous elements in the present Class IV. are rather in excess. A valuable series of tables setting forth the chemical composition of the proposed diets and comparing them with those at present in force will be found in Appendix II., to which is attached an instructive summary. The dietary for convicts has been increased in quantity and rendered superior in nutritive value as well as more varied in character. One uniform hospital dietary has been introduced for all the prison hospitals both convict and local. The penal system of dietary has been reformed and the terms for which prisoners can be subjected to dietary punishment have been reduced. With regard to food-supplies the whole-meal flour employed for making bread has been severely criticised: it appears to contain more bran than the specifications allow. It is stated to be essential for the well-being of prisoners that the supply of potatoes should be regular and constant, that samples of food-stuffs should be of recent date, and that stores should always be according to sample; that the appliances for the preparation and cooking of the food are capable of improvement; that it is very desirable that cooks, bakers, and millers should undergo a course of systematic training; that the tin utensils used in the service of the food should be replaced by enamel ware; that where land is available the cultivation of fresh vegetables should be encouraged at convict prisons and that they should be freely used in the dietary; and, finally, that the appointment of a well-qualified and competent inspector of food-supplies is necessary.

The whole report shows evidence of careful drafting and it is apparent that the committee spared neither time nor labour in endeavouring to arrive at a definite opinion regarding the important questions submitted to their judgment.

THERE appeared recently a letter from a medical man in the lay press[1] signed "FAIRFAX" and written possibly by Lord FAIRFAX, a medical peer resident in America. This letter was entitled "The Unrestrained Lunatic Danger" and it invited public attention to a real source of danger to the community while touching the fringe of a much larger question, "Why is it that so many lunatics are at large and unrestrained from being a danger to the community?" The answer which "FAIRFAX" gives to this is, though perfectly correct, only a partial one—viz., that it is difficult to get medical men to certify to a patient's insanity and fitness for detention in a public or private asylum because they know that if the patient gets temporarily better and is released he will almost certainly bring an action against them. Concrete instances such as the following are not unknown to practitioners generally and are well known to lunacy practitioners. A woman who became insane and was duly certified and detained in an asylum for treatment recovered and was eventually discharged. In the interval between her detention and discharge she had succeeded to a sum of £2000, which sum she at once started to invest in legal proceedings against the medical man who certified her insanity. This of itself would show that her mind was not well balanced and sound, and in addition the trial at the High Court of Justice and before a jury further showed that the evidence of her insanity was complete. She lost her case. The woman thereupon, to avoid payment of costs, went through the Bankruptcy Court. The medical man who had to incur large legal expenses in his own defence, failing to get "costs" in the action owing to the woman being a pauper as well as a bankrupt, had to sell all that he had saved and "begin again." This is far from being an isolated case. Physicians who have had experience of lunatics know well, and have at times to their regret felt, the unreasoning rancour and vindictiveness of certain types of patients, notably those of the chronic alcoholic, delusional, and so-called monomaniac kinds, who with unceasing and persistent hatred will follow and persecute the unhappy practitioner who has had a part in certifying them or in otherwise contributing towards their detention. "FAIRFAX" himself asserts that he has not signed a certificate for many years, though he has often been solicited to do so, and other practitioners frequently refuse their signatures. The consequences are therefore serious, for as the result of general refusals numerous lunatics are now at large from this cause alone. "FAIRFAX" mentions two within his own knowledge and others can be adduced. That this constitutes a real danger to society cannot be questioned. It may happen that in some patients their insanity will assume a homicidal form, in others a suicidal form, and in others a variety of persecutory, violent, litigious, or criminal forms. All are more or less dangerous to the community while but few, excepting the suicidal kind, are dangerous to themselves. Up to 1889 medical men signing lunacy certificates were by law liable if the patient was subsequently found sane by a jury, even though the physician had acted in good faith and with all reasonable care in making his statements and signing the certificate. The consequences were that very few medical men, except specialists, would sign one at all and it became "difficult even in the most obvious cases to get a certificate signed."[2] Since 1889, however, the Act provides[3] that the certifying practitioner shall not be liable to prosecution if he has acted "with good faith and reasonable care." This, however, is a matter that cannot be legally decided beforehand; it is not possible legally to establish before the patient is deprived of his liberty and placed under asylum care that the physician certifying is acting *in good faith and with reasonable care*. Hence the patient after his recovery and release may bring an action against the certifying practitioner alleging want of such good faith and care with the result that the medical man has to go through legal proceedings before a higher court and has to show to the satisfaction of the court that the charge is groundless and that it cannot be sustained. Further proceedings can then be stayed but only after the practitioner has been put to expense of time, labour, and money in establishing his case to the satisfaction of the court. Thus it comes about that the statute of 1890, though it has in appearance at least rendered the process of certifying less dangerous to the medical man concerned, is still defective in permitting the infliction of annoyance and expense upon him, even though he has closely conformed with its regulations and has done no wrong. Accordingly medical men are chary of certifying—some refuse point-blank ever to certify—and the consequence is that certain lunatics of a dangerous type are allowed to go freely at large and when a crime is committed and it is found to have been the act of such a lunatic there is an outcry in the public press and as likely as not its object is a medical man. Now, the medical man cannot be expected to watch and guard society and to avert such disasters when for his action in so doing he has, owing to the unsatisfactory state of the law, to lay himself open to vexatious, harassing, and costly litigation. He cannot, and ought not to, be required to be at once a dutiful servant of the public and a scapegoat.

---

[1] St. James's Gazette, Feb. 17th, 1899.

This state of things is surely capable of alteration and improvement; and the recent interview between a deputation representing a joint committee of the British Medical Association and the Medico-Psychological Association and the Lord Chancellor (an account of which will be found in THE LANCET of March 4th, p. 604) points to one possible remedy. Various suggestions are feasible but they should all possess this characteristic—that while the interests of the medical profession are safeguarded the process of depriving an alleged lunatic of his liberty should be in no case open to abuse and should be demonstrably above the reach of bribery and corruption. The history of lunatics in asylums during the "fifties" and "sixties" has shown that such abuses did at one time exist. Let a clause, then, be added to the Lunacy Act modifying the provisions of Section 330 in such a way that it would be impossible to bring an action against any certifying medical man except on the ground of bribery, corruption, or conspiracy. If any of these be alleged let a magistrate be empowered after due examination of the case to certify that there is or is not a *primâ-facie* case to go before a higher court; and if the former that the plaintiff should give ample security for costs should he or his advisers insist on taking the case before a higher court. The ends of justice would thus be met, the rights of the medical practitioner as well as of the lunatic would be *safeguarded*, and needless and vexatious litigation would be avoided. The benefits to the community would be that in a short time the number of dangerous maniacs now roaming at large would be greatly diminished, the guarantees of social security increased, and medical men, who are after all servants of the public, would be unfettered in the discharge of a necessary portion of their duties.

◆

AN obvious and admitted defect in the education of the medical student at the present time is undoubtedly the comparative absence of proper clinical instruction in midwifery. As a rule only the students who have attended the practice of a lying-in institution have full opportunity of seeing the performance of obstetrical operations, while but few have a chance of performing any of these operations themselves. And yet the midwifery forceps has been well termed by BAUDELOCQUE the most important of all surgical instruments and it is undoubtedly the instrument which is most frequently in the hands of the general practitioner.[1] This defect in the practical teaching of midwifery is unfortunately one for which, when the nature of the circumstances is considered, there is little prospect of any remedy being found. It is very unlikely, even supposing that lying-in hospitals were provided and that the general practitioners of the country were not quite able and willing to deal with the general midwifery of the country, that the women of the poorer classes would consent to enter such hospitals; and it is quite certain that if any attempt were made to utilise the material thus obtained for clinical instruction to the same extent as is done in many of the lying-in institutions abroad it would be quite impossible to keep the beds full. We do not wish performance of, at any rate, the simpler obstetrical operations; such a contention would be quite untrue. Any student with an average amount of intelligence and dexterity could be trusted to apply the midwifery forceps for the first time with complete success. It is not so much teaching in the methods of performing the various operations which is required as clinical instruction in the indications for their employment.

---

[2] Pitt-Lewis, Smith, and Hawke in Lunacy Law for Medical Men, 1896.

[3] Vide Lunacy Act, 1890, section 330.

The simplest rule which can be laid down for the application of midwifery forceps, and one upon which everyone is agreed, is that the forceps should be employed when their use is attended with less risk to the patient than leaving her alone. Such a rule is a very easy one to enunciate, but the difficulty lies not in its enunciation but in the determination of the various conditions in actual practice in which it will apply. Anyone with a large experience of midwifery practice will know how varying are the circumstances and how varying are the cases in which the application of the forceps is good and correct treatment, and how exceedingly difficult it often is to determine whether the use of the forceps will be attended with greater risk to the mother than the neglect to use them. And yet only too often the young medical man upon first entering practice is called upon to come to such a decision in a difficult case of labour, and the only resources he has to fall back upon to assist him are the theoretical knowledge which he has gained from his text-books and his lectures, and the small amount of practical experience which he has acquired in attending the requisite number of cases of labour, an experience that may not have included a single abnormal case. Little wonder is it, then, that from time to time the young practitioner, yielding perhaps to the importunities of the patient or of her friends, applies the forceps in cases where a man of greater general or special experience would have thought it better to stay his hand.

There can be little doubt that, largely owing to the more extended use of anæsthesia and antiseptics, the midwifery forceps are applied more frequently at the present day than formerly. The question is one of the greatest possible interest to all engaged in midwifery practice and it becomes a matter of great importance to determine whether the increased use of forceps is attended with increased risks to mother and child. If we take into consideration only those cases in which the use of the forceps is clearly indicated and in which no exception can be taken to their employment the answer is certainly in the negative. But various arguments have been brought forward lately to lead us to believe that the abuse of the midwifery forceps is on the increase and that as a result of this the number of cases in which bad results can be directly traced to an improper use of the forceps has been largely augmented. An example which is often cited is the frequency of rupture of the perineum in cases where the forceps have been used. But evidence is accumulating which tends to show that by the use of the axis traction forceps the danger of rupture of the perineum is largely diminished and in fact it appears extremely probable that in a large number of cases by the use of such instruments the perineum can be often saved when it would without their employment inevitably have given way. It is impossible to deny that cases may occur from time to time in which the forceps are used improperly and under such conditions as to increase rather than to lessen the risks to both mother and child. If such an abuse of the instrument exists to any great extent (and we know of no reliable evidence that such is the case), then the cause must be either a want of power on the part of the practitioner to recognise with certainty the special circumstances under which the forceps are indicated or an error of judgment dependent upon an inadequate knowledge of the exact course of normal labour. The number of such mistakes must very largely depend upon the training which the medical man has received as a student and the ultimate blame must therefore be laid upon the shoulders of his teachers or upon the methods of teaching.

Annotations.

"Ne quid nimis."

THE POPE'S RECOVERY.

"PLAIN living and high thinking" have "scored" again and the nonagenarian Pontiff, after an illness followed by an operation which within 24 hours brought 10,000 telegrams of inquiry to the Vatican, has been allowed to leave his bed and, seated in his armchair by the now historic window, to look out on that world from which he has been excluded for more than 21 years. His case in all its incidents and surroundings is a memorable one. Other pontiffs indeed have shown marvellous vitality, though out of the total of 263 16 only have seen their eighty-first year. His immediate predecessor, Pius IX., lived until he was 90 years of age and alone of all the Popes "surpassed the years of Peter" (25) on the papal throne. Clement XI. died in his ninety-third year. Paul IV., elected at 89 years of age, lived four years afterwards; and Gregory IX. died all but a centenarian. But none of these Popes, except Pio Nono for a few years, was a "prisoner," confined to a "palace and a garden," as Leo XIII. has been since February, 1878. They could all leave the Vatican for the Quirinal and both these palaces during the dog-days for Castel Gandolfo, that superb villa overhanging the Alban Lake, well-nigh 2000 feet above sea level. Change of air and change of scene were open to them. But Leo XIII. has never stirred beyond that Mons Vaticanus which retains the insalubrious character given it by Martial. None of them, moreover, in their ninetieth year had to undergo the enucleation of an inflamed cystoid tumour of a quarter of a century's standing, and all this amid the cares of a spiritual empire infinitely greater in number and complexity than the busiest of them ever knew. Of course, in the present case the "personal equation" counts for much. Leo XIII. comes of the ancient stock of the Peccis, mountaineers of the Latian and Neapolitan frontier. From his youth up an indefatigable scholar, he relieved the seclusion of the study with open-air exercise, and during the many years he was Archbishop of Perugia indulged in field-sports mainly with his gun. Then, again, he was happily gifted with the "mens æqua" of his favourite poet, conducing to that even flow of the circulation which is marked by "the pulse of longevity." Over and above this constitutional characteristic he has always had the "will to live," which in the physical sphere is the counterpart of what the greatest of American psychologists has in the religious life called the "will to believe." This effort of volition, conscious or unconscious, is quite compatible, as in Leo's case, with absolute courage in face of death. Indeed, before and after the operation the Pontiff's cheerfulness almost rose to gaiety, expressing itself in pleasant sallies, doubly pleasant for his consultants to hear. It may or may not be truly stated that he congratulated himself, as a hopeful element in the prognosis, on his "having youth on his side." But he certainly spoke and acted as if he had—as if, indeed, he fully shared Professor Mazzoni's belief that after the operation he had at least as many years in store as would suffice to falsify the words whispered into his ear on coronation, "Non videbis annos Petri." His example adds another to the many instances of patriarchal years attained by hard working men, professional and other, in whom "mind and soul according well," with a physique unbroken by excess and braced by manly exercise, have resulted in that "old age" immortalised by Wordsworth as "beautiful and free." That poet himself and his official successor, Lord Tennyson, the Duke of Wellington, and the Emperor William I. are typical examples of that serene "sunset of life" which, succeeding its "fitful fever," shed so rich an afterglow on their decline.

CHILD LABOUR AND ITS HYGIENIC ASPECTS.

AT a recent meeting of the London School Board (Feb. 16th, 1899) a report was presented dealing with the results of inquiries relating to those unfortunate little children in London who have to labour out of school hours for a partial livelihood of their families. The material collected and set forth by Mr. Macnamara reveals a state of things generally unknown to the public and one in need of medical and social reform. The report shows that 1143 children work from 19 to 24 hours a week, exclusively of school hours; 729 work from 30 to 39 hours a week, and 285 children work 40 hours or more a week. The occupations include such as newspaper and milk delivery, shop and factory work, errands, greengrocery, domestic work, and various other employments. At the Aldenham street school, Marylebone, one of the boys works for from 23 to 24 hours a week as an undertaker's help assisting in the gruesome task of measuring corpses, and receiving 1s. a week for his work. Several of the boys work during the afternoon break (of one hour) between school hours. One little lad in Stepney works as a greengrocer's help nearly eight hours every school day (exclusively of school hours), all Saturdays till half an hour past midnight, and three hours on Sunday. The effect of this extra mural labour is that the victims reach school tired and sleepy and quite unfit for their work. "Probably," says the report, "some die as the direct result of the severity of the toil inflicted upon them during their early years, and certainly many more of them must become a permanent and heavy charge upon the public purse because of the physical incapacity resulting from the rigour of their early experiences." It has been suggested that the London County Council which in another direction controls the employment of child performers on the stage should frame by laws preventing labour of those under 14 years of age before 8 A.M. or after 8 P.M., in which case a distinct step in advance would be achieved. Dr. Francis Warner who has patiently studied the physique and capacities of board school children in London for many years stated recently[1] that *physical hygiene* should be studied in these children as well as *mental hygiene*, that the capacity for acquiring and assimilating knowledge was at its best when the child was fresh and not suffering from fatigue, and that many school children unfortunately showed more or less brain fatigue as manifested in their want of accuracy and ease in coördinate voluntary movements (which were also fewer), while "uncontrolled movements" were more common in these children, such as finger twitchings, contraction of the forehead, unequal balance of outstretched arms, with drooping fingers instead of level when in that position, and slower and more inaccurate response to questions, &c. There can be no question of the importance of public attention being drawn to the matter and the London School Board has already taken some action, having resolved to send a letter to the Education Department urging their lordships to call upon the various rural educational authorities to take steps to prevent the illegal employment of children of school age in their districts in labour of various kinds.

THE ILLNESS OF MR. RUDYARD KIPLING.

MR. RUDYARD KIPLING is now pronounced out of immediate danger. His illness was apparently of a complex type combining the wandering form of broncho pneumonia with the definite crisis typical of ordinary lobar pneumonia. It has been considered that Mr. Kipling's attack was certainly consecutive to influenza because of the illness of his two little children, but his medical attendants do not seem to share this view. The universality of the interest which has been taken in Mr. Kipling during his illness is a testimony to the wonderful hold which he has taken upon the minds of men. The vigour of his genius, the nobility of his motives, and the dexterous audacity of his literary methods have gained for him a wonderful audience, so that we find the occupant of the throne and the third form schoolboy, the great poetic artist and the hard headed merchant, the lettered and the ignorant, alike in their sincere admiration, and we may be sure that they are alike also in their sympathy with him and his wife in the sad death of their eldest born.

THE NEW FOOD AND DRUGS BILL.

TWO weeks ago we noted with satisfaction that Mr. Walter Long had evidently grasped the need of repeal that was wanted in regard to the present Food and Drugs Act (1875). This at any rate was the impression which he conveyed in his remarks, which almost amounted to promises, made before a deputation which had sought his assurances. But the Bill introduced by Mr. Long into the House of Commons this week would seem to imply that the Government do not mean to deal with the question with that comprehensiveness which it demands. Indeed, it suggests very little at all in the way of repeal of the sections of the present Act. The only reforms which we can pick out from the Bill, a copy of which we have before us, relate to increased fines, to the form of the certificate of analysis, and to a little extra procedure to be observed when a sample is purchased. These are practically all the steps which it is proposed to take as a result of the recommendations of a Select Committee which laboured on the question for four years. There is to be no Board of Reference, no standards are to be set up, no requirements about preservatives are mentioned, and no particular qualifications are to be demanded from the person filling the office of public analyst. We cannot frankly regard the Bill as a Sale of Food and Drugs Bill at all. Of the 23 clauses in it no less than 11 deal with agricultural products, while eight have to do with the sale of food and drugs, and the remaining four are merely supplemental. In the section dealing with food and drugs there are no definitions laid down. If this Bill passes then it seems to us that the labours of the Select Committee may very reasonably be counted as so much wasted time and money. In reality the Bill is a measure dealing mainly with agricultural products and home produce, aiming at the stopping at the ports of entry of the importation of adulterated articles such as butter, cream, and milk. It will appeal, therefore, very strongly to the home producer and thus Mr. Long will probably secure the support of the agricultural industry. But this is narrowing down what should be a very broad piece of administration. The discussion of the Bill on the second reading is to be continued in the House of Commons this week (Thursday). We must confess that we should learn with satisfaction that the measure was rejected. We understand that an alternative measure is to be introduced by Mr. Kearley. If this measure is drawn up on the plan of the one introduced by that gentleman last year we should like to see it supported on all sides and become, as we believe it could, a workable and a really useful and protective measure.

PUBLIC ABATTOIRS.

IN the *Irish Times* of March 6th is a long and important letter from Dr. C. F. Moore dealing with the question of the supply of a public slaughter-house for Dublin. We have over and over again expressed our views as to the enormous advantages which public abattoirs possess over private establishments in at any rate urban communities, and Dublin seems to be a town where the need of a public abattoir is especially felt. 20 years ago the Royal Commission of 1879 reported that the offensive condition of the foreshore of the River Liffey was most likely largely due to the offensive waste from the slaughter-houses, and still there are over 60 slaughter-houses within the city and there is no authoritative inspection of either meat- or milk-supply. One public abattoir has been built but without the jurisdiction of the city authorities, so that there is no power to compel the butchers to use it. Here in London we are fighting hard for the abolition of the private slaughter-house but we have the London County Council on our side. In Dublin apparently the municipality have neglected not only this but other equally pressing sanitary reforms. Let us hope that the new Local Government Act for Ireland will be the means of bringing about much-needed reforms.

MORBIFIC OYSTERS IN MILAN.

IT was not until the end of 1898, says a writer in *Saluta Pubblica*, that oysters were for the first time inculpated as the diffusers of cholera, the occasion being a small outbreak of that pestilence which took place at Grimsby and which was recorded in a report by the Director-General of Public Health in England, Sir Richard Thorne, but the fact that these molluscs might become the vehicle whereby the germs of typhoid fever could make good an entrance into the human organism had long before been demonstrated with mathematical exactitude by a great many competent observers in various parts of the world. As long ago as 1895 we published an article in THE LANCET[1] in which the incrimination of infectious oysters as carriers of typhoid fever was conclusively established. The fact that the disease could originate thus was therefore perfectly well known among men of intelligence. On this head no doubt was possible, not even the slightest, just as there can be none regarding the contaminating influence of polluted water. Even if bacteriological research had been successful in demonstrating the presence of the typhoid bacillus in oysters the experiment would simply afford confirmatory evidence of what was already known. The failure so far to isolate the bacillus in the mollusc does not by any means disprove its existence there. It merely serves to show the enormous difficulties that attend upon microscopical investigation. Such being the state of the case the chief medical officer of the sanitary office in Milan, in which city typhoid fever has been committing terrible ravages, conceived it to be his duty, as in reality it was, to warn his fellow-citizens that in consuming oysters they were running a great risk of acquiring an extremely troublesome and dangerous malady. But it happens that the oyster industry in Milan is one of considerable magnitude, affording occupation to a large number of persons. At once a loud and bitter outcry arose. The health officer for no cause or reason whatsoever was trying to deprive honest tradespeople of their sole means of gaining a livelihood. He was an ignoramus, moreover, and his outrageous proclamation betrayed *him*. To accuse the poor, innocent, toothsome oyster of disseminating typhoid germs was a wicked fable flippantly enunciated, but happily the refutation of it was an easy matter. "Spurious scientists" might not be aware of the fact but amongst real men of learning it was well known that the disease could only be caused by a certain microbe, and that this particular species had never yet been discovered between two oyster-shells. An official, highly placed, should be aware of such an elementary truth; it was disgraceful; it was frivolous—and so on. In all lands, civilised or otherwise, the sanitarian is accustomed to misrepresentation and vituperation, but an endeavour to hoist him with his own petard would seem to be a new departure in the gentle art of malediction. Billingsgate has long been renowned, but if this be so the honour and glory of initiating a new form of abuse belongs to the Milanese oystermen.

CODRINGTON COLLEGE, BARBADOES.

CODRINGTON COLLEGE is practically the University of the major part of the West Indies. It was founded in 1710 by General Codrington for the purpose of training West Indian youths to enable them to devote themselves to "the Christian ministry in their native islands." The founder endowed the college with two estates, but these estates, owing to the depression in the sugar industry, are now no longer productive enough to support the college. Owing to the craze for cheapness cane sugar has been supplanted by the greatly inferior sugar from the beet, and so Codrington College, like so many other foundations endowed with land, has fallen upon evil times. Unless a minimum of £5000 is obtained by May 1st the college will have to be closed on June 29th. A letter has been sent to the press signed by the Archbishop of Canterbury and others appealing for funds. Subscriptions may be paid into Messrs. Drummond's bank and cheques should be made payable to "The Trustees of Codrington College or Bearer."

PANCREATIC LITHIASIS.

THE *Journal de Médecine Interne* of Feb. 1st contains an important lecture by M. Lancereaux on this little-known subject. Pancreatic lithiasis is one of the commonest affections of the gland but it is much rarer than biliary lithiasis. Including one under his own care, M. Lancereaux has collected 40 cases; there was persistent diabetes in 12. The etiology has received little attention. Atheroma of arteries, hepatic and renal lithiasis, and chronic rheumatism are frequently associated with pancreatic lithiasis. Possibly the same general condition is a predisposing cause of all. The age at which pancreatic lithiasis is observed (from 30 to 60 years) favours this view. Sedentary life and over-feeding are predisposing causes, as they are of biliary lithiasis. Obstruction, by pressure of a tumour, for example, is an exciting cause of both. Calculi are found in all parts of the gland, but especially at the head. Sometimes there is only one, sometimes a number are present; 300 have been found. They are usually free in the ducts but they may be fixed in the gland. They are spherical, ovoid, or cylindrical; rarely they are granular or arborescent. They vary in size from that of the head of a pin to that of a hazel-nut. Lesions of the pancreas may result. The ducts become dilated. Aided by the stasis microbes enter from the intestine and produce suppuration or gangrene; then there are rigors, fever, and septic symptoms. In other cases sclerosis of the gland and atrophy of the cells result; the pancreatic function fails and a fatal diabetes ensues. Physical signs are rarely found in pancreatic lithiasis. A case is related in which there was an epigastric tumour; this was doubtless a cyst consecutive to dilatation of the canal of Wirsung. The only other sign is the passing of calculi in the stools; the calculi are found by careful sifting and are whitish and composed almost exclusively of carbonate and phosphate of lime. Colic is less frequently produced than in the case of biliary calculi in consequence of the feeble contractility of the canal of Wirsung. The habitual seat of the pains is between the umbilicus and the epigastrium, often at the left costal margin; they radiate along the costal arches to the spine; they are acute but not so intense as those of hepatic colic; and like the latter they are accompanied by anorexia, rigors, cold sweats, nausea, and vomiting. With each crisis occur certain still more important symptoms—glycosuria, fat in the stools, and sometimes, though rarely, in the urine; there are also polyuria, polydipsia, and polyphagia. In fact, there is complete but temporary diabetes, due no doubt to inhibition of the pancreatic secretion analogous to the inhibition observed when one ureter is obstructed by a calculus. Intestinal hæmorrhages have been noted in three cases and passing jaundice in three others. Colic occurs at the beginning of the lithiasis. Later, when the pancreas is profoundly altered, what M. Lancereaux calls "diabète maigre" sets in. The duration of pancreatic lithiasis is variable—days, weeks, a year, several years; the prognosis, too, is variable. If the calculus is passed into the intestine by the duct or by ulceration recovery is possible, but if the duct remains obstructed suppuration, gangrene, and death from septic infection, or sclerosis and atrophy, and death from diabetes, are to be feared. The calculus has passed into the abdominal cavity with fatal hæmorrhage in one case and with peritonitis, almost always fatal, in several. Pancreatic colic is to be distinguished from gastric cramp The pain in the former radiates from the pit of the stomach and in the latter from a little above the umbilicus; it is distinguished from biliary colic by the (usual) absence of jaundice. If in a case of diabetes with wasting there is a history of pancreatic colic the origin of the diabetes in pancreatic calculus is probable. Prophylaxis as in biliary lithiasis consists in exercise, stimulation of the skin by cold douches, and regulation of the diet. Morphia is to be used to relieve pain.

---

[1] THE LANCET, Feb. 2nd, 1895, p. 307.

THE DEATH SENTENCE AND CRIMINAL ABORTION.

Mr. Justice Darling on Monday last in charging the grand jury at Chester Assizes referred at length to the case of William Upton who is alleged to have killed a woman named Mary Murray at Macclesfield by means of an illegal operation. The learned judge referred to the notorious cases which have recently been tried and pointed out that where the death sentence had been pronounced everybody in court knew that it would not be carried out. Such a state of the law, he considered, put judges in an undignified and absurd position. It was not well that the highest penalty which man had it in his power to inflict should be gravely decreed against criminals with the full knowledge that the whole proceeding was nothing but a sham from the beginning. He advised the jury upon his own initiative and until some consensus of opinion had been arrived at in the matter not to return a true bill for murder if they thought that the wound though inflicted for an unlawful purpose was not intended to kill and only to find a true bill for murder when it was intended to kill the woman, or at any rate when those who performed the operation did not care if the woman died or not. The grand jury adopted Mr. Justice Darling's suggestion when they came to deal with the matter and we are glad that they did so, for his lordship's advice runs with our own expressed opinion that the Treasury (the almost inevitable prosecutor) should always indict for manslaughter only—unless of course suspicion is present that a deliberate attempt has been made to take life by a uterine wound.

THE HEALTH OF THE PORT OF LONDON.

Dr. Collingridge's half-yearly report on the work of the Sanitary Authority of the Port of London shows that in many respects there has been great improvement and that a higher standard of sanitation is gradually becoming possible. The report states that during the half year under notice 16,127 vessels were inspected, a larger number than in any previous half year since the formation of the authority in 1872. Of the total number of ships visited 82·37 per cent. were under the British flag, while of the Scandinavian ships, the next highest in order, 8·89 per cent. were visited. The medical inspection of vessels on arrival at Gravesend is still carried on satisfactorily in conjunction with Her Majesty's Customs and in this way 5456 vessels from foreign ports were examined. Detailed notes are given of the cases of plague which occurred on vessels entering London from Eastern ports. Two inspectors have been specially appointed for the work of inspecting food. It is mentioned that the imports of mutton into London from all parts have increased from 400 carcasses in 1880 to nearly 4,500,000 in 1898 and the fact is noticed that the condition of frozen meat on arrival is gradually improving.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION AND HABITUAL INEBRIATES.

We have before us in a separate form the Presidential Address of Dr. A. R. Urquhart to the Medico-Psychological Association of Great Britain and Ireland in July last on the occasion of its annual meeting in Edinburgh and find in it not only ample vindication of the work and purposes of this Association, but sundry criticisms on current questions which are worth reverting to. The growth of the Association is shown by the increase of 124 in the membership as compared with the numbers 10 years before. Dr. Urquhart referred with much confidence and satisfaction to the Laboratory of the Scotch Asylums started by Dr. Clouston and aided by the Edinburgh College of Physicians as having been already of distinct service and promising much usefulness in the future in the way of favouring research in all that affects insanity. Dr. Urquhart suggests that the answer to the question—Is insanity on the increase? should be in an indication of all the means by which such increase may be mitigated. He magnified the work of Conolly and showed how the points for which he fought and pleaded in his address to the Association in Edinburgh in 1858 had been practically gained. Dr. Urquhart lamented the absence of legislation for increasing the number of Commissioners in Lunacy, the present number being the same as when the Commissioners were first created to control a number of insane only one-fifth of those now to be cared for. He deprecated all legislation that tended to make the asylum physician a mere official and which opposed freedom of initiative and the range of personal responsibility in the medical superintendent. His remarks on the Inebriates Bill were interesting. He accepts it as a great advance on the Act of 1879 but considers it as a mere instalment. He cannot regard the responsibility of the State towards the victims of drunkenness as discharged by a provision only for those who come under police notice. He has had in 18 years in Murray's Asylum 85 habitual drunkards under his care not half a dozen of whom would have been affected by the provisions of the Act of 1898. His remarks on drunkenness and the nature of the institutions in which it needs to be treated are full of suggestion. He would not wait for "its terminal dementia" but would largely employ early means for frustrating habits of vice or disease. He gently reminds the Association that it has not done all the good on this subject or given all the attention to it which it might have done. We can only hope that future presidents and members will take the hint and give some scientific turn to legislation and work for the benefit of that large proportion of drunkards who are not reached by any legislation at present but are left, to use Dr. Urquhart's words, "to stagger on their way to perdition" often dragging their families in their train.

THE DEATH OF THE REV. DR. BOYD.

ONCE again a valued life has been lost from poisoning through the plan of keeping bottles containing virulent lotions with bottles containing medicines for internal use in such a way that the two remedies are liable to be mistaken for each other. The Rev. Dr. Boyd, popularly known as a writer above the initials "A. K. H. B.," was in the habit of taking sleeping draughts and used also a carbolic acid lotion. The bottles containing these remedies were kept in the same place and in coverings closely resembling each other. The evidence at the inquest showed that the unfortunate gentleman met his death by drinking the corrosive lotion instead of the sedative draught, the mistake probably arising from his omission to remove the wrapper. Accidents of this kind take place in spite of the many contrivances which have been suggested to prevent them. In our columns from time to time we record the invention of new bottles to contain poisons—bottles of various distinguishing shapes, bottles with sonorous "alarms" attached to them, bottles with impediments to their outflow; but such devices, while serving as checks to error sometimes in a very ingenious manner, do not take the place of human intelligence. The catastrophe usually occurs in the case of chronic invalids and when the process of administering the medicine has become an habitual and almost a mechanical one. Care, constant care, is the only talisman which will prevent such accidents, and every medical practitioner should impress this fact upon his patient as well as upon his patient's friends, especially when from the nature of the case a poisonous remedy is likely to be in long use.

THE VICEROY OF INDIA ON MEDICAL SCIENCE.

THE *Times* correspondent in Calcutta telegraphs to that paper a long account of Lord Curzon's speech made at the annual meeting of Lady Dufferin's Fund, held on March 3rd, in which his Excellency is reported to have used the following words:—

"Now I come to the last boon of science, and medical science in particular. About this no two opinions can possibly be entertained. There may be prejudices and scruples arising from long custom, ignorance, or other causes, but doubts there cannot possibly be, and I say this, that if we had come back to you from the West with our medicine in our hand, and with that alone, we should have been justified in our return. For what is this medical science we bring you? It is no mere collection of pragmatical experimental rules. It is built on the bed-rock of pure, irrefutable science; it is a boon which is offered to all, rich and poor, Hindu and Mahomedan, woman and man. It lifts the *purdah* without irreverence. So far as I know it is the only dissolvent which breaks down the barriers of caste without sacrilege. Medical science, indeed, is the most cosmopolitan of all sciences, because it embraces in its merciful appeal every suffering human being in the world."

Lord Curzon's words will be a cause of great pleasure to the profession upon which he has bestowed this eloquent panegyric. Above all things, medicine desires to know no artificial limitations to its scope. To all religions and castes, to all races, and to all social grades alike it offers such assistance as in the present state of the world's knowledge is in its power, the only claims upon it that are recognised being those of disease. We thank Lord Curzon for his public and graceful expression of this view, particularly as there are circumstances now occurring in our Indian Empire which make such expression of unusual significance.

THE DANGERS OF THE KINEMATOGRAPH

NEARLY two years ago we pointed out the desirability of placing kinematographic demonstrations under rigid inspection and control on account of the exceedingly inflammable and almost explosive nature of the celluloid films employed in the apparatus. We said "the danger is no imaginary one," and a recent occurrence at a theatre in Hammersmith fully confirms this statement. Fortunately, however, it was only a rehearsal that was going on. An electrician in charge of the apparatus was terribly burnt, while another person luckily escaped injury although his clothes were burnt. It is stated that suddenly something went wrong with the film and immediately flames shot up, followed by a loud explosion which resulted in the complete destruction of the kinematograph celluloid roll. The combustion appears to have been actuated by a defect in the electric wires. The occurrence shows how easily a panic in a "full house" could be started with the extreme probability of shocking sequelæ. We believe that the London County Council take steps to insure the safe working as far as possible of this apparatus by regular inspection. We trust that they and all other similar authorities in the country will not relax their action one iota in this matter, for the kinematograph as a source of amusement and, we may add, of instruction is being very largely employed in crowded places of public resort. It is imperative, therefore, as we have said before, that some action should be taken to provide as far as possible for the safety of the great numbers of those watching this kind of entertainment.

PERFORATIVE PERITONITIS.

MR. CHARTERS J. SYMONDS recently delivered a most interesting address before the Hunterian Society on the Individual Value of the Symptoms in Perforative Peritonitis, more especially as Regards Operation. Abdominal surgery has made huge advances during the last few years. Physicians when confronted with evidences of acute peritonitis are becoming more and more convinced of the value of obtaining a surgical opinion, for they fully recognise that an early operation has been the means of saving numerous lives, whilst even if an error has been made in diagnosis (and the diagnosis of such cases is attended with countless difficulties) such an operation is rarely productive of permanent harm. Mr. Symonds considered in detail the various symptoms met with in perforative peritonitis. Dealing first with pain he stated that if this symptom occurred at the onset of the illness it was no doubt an indication of severity, allowance being made for the difference in the ability of patients to bear pain (very often an anxious question for the physician). When the pain is limited to the right iliac fossa its value as to the seat of trouble is obvious. The lecturer was also of opinion that when the pain is continuous and distinguished from mere tenderness, and when pain recurs after a period of repose, an operation is indicated, and he insisted on the absolute necessity of not obscuring this valuable sign by the continuous use of sedatives. General abdominal distension and immobility are two of the most important symptoms. In all cases the general distension which does not yield to a tube (or turpentine enema) on the second or third day indicates progressive disease and the case will probably require operation. When a perforating gastric ulcer is suspected there may be no distension for from 12 to 24 hours, at which period it is a serious symptom. In appendix cases, Mr. Symonds said, general distension without localised tumour, without dulness, but with pain and tenderness, has a grave significance; if with the points just mentioned the temperature is continuously raised the case is still more grave and may call for immediate operation even 48 hours after the onset. After referring to other symptoms which might be noticed after general distension has subsided or yielded to the flatus tube or an enema the value of vomiting as a symptom was commented on. Whilst it always accompanies the onset of perforation it may be, and often is, absent in cases of gangrenous appendicitis. As a symptom of onset it indicates severity or suddenness and is present in most cases which run a favourable course. If it recurs after careful feeding, rest, and a sedative it becomes an alarming symptom and as a rule the case demands immediate surgical interference. Of all the symptoms it may as a single one be most relied upon. Mr. Symonds further observed that if vomiting be an important symptom its absence has a significance equally great; in fact, he would be disposed to say that the absence of vomiting causes more anxiety when the question of operation is raised than its presence. We must not, however, wait for this sign; if we do the only opportunity for operation may be lost. We must remember that strict abstention from stomach feeding retards for a time its occurrence and when vomiting does recur under careful treatment the end is probably near. Passing on to the important question of temperature Mr. Symonds quoted cases illustrating the fact that temperature and pulse may steadily fall while dangerous septic processes are advancing, and therefore the absence of pyrexia at the time when we are called to decide the question must be discounted in the face of a reliable history of onset, of early fever, and the fact that the patient is not decidedly better after from four to six days from the onset. Mr. Symonds had many interesting and instructive remarks to make as regards the "period of repose" and the "general condition" of the patient, the first named being especially characteristic of the cases under discussion. He is to be congratulated on having succeeded in conveying so much information in one lecture.

INFLUENZA.

INFLUENZA still continues to strain the powers of medical men and to disable more or less a large proportion of their patients without respect of persons. Statesmen, diplomatists, writers, masters, servants, nonagenarians, and infants are attacked with splendid impartiality. To do the present epidemic justice it does not generally deal so severely with its victims as in the past, and though the number of deaths is still considerable the mortality is much less than on several previous occasions, especially when we consider that winter cold has been in operation, assisted by fogs, for a fortnight past. Most of the cases continue to be of the nature of a febricula, the rise of temperature being sharp and its duration short, with or without catarrh. The pains vary much, but are often eloquently described as severe by patients who do not exaggerate their sufferings. One patient will say that "it feels as if his legs were broken in 20 places," another "as if her back were broken in two." In some cases the pyrexia extends over a week, in others over many weeks, in many of the latter consolidation of the apex of the lung, which gradually abates, being present. Though the profession is sometimes bantered on the subject it continues to be much consulted, and there is no doubt that the longer the attack is ignored the longer will be the duration and the more severe the consequences. The wiser members of the public perceive that if the knowledge of medical men is incomplete there is danger in neglecting to seek their services. People talk as if this were a new experience altogether, but it is not so. The letters of Disraeli written about the year 1837 show a similar state of matters with much damage to the plans and convenience of public men.

THE REMOVAL OF ADENOIDS IN INFANCY.

FORTUNATELY post-nasal adenoids when they are present in young infants do not commonly give rise to troublesome symptoms There are exceptions to this rule, however, and one such is quoted by the *Journal de Clinique et de Thérapeutique Infantiles* of Feb. 23rd. In this case the child was aged four months. He had suffered at birth from purulent ophthalmia, a fact which may partially explain the urgency of his adenoid disorder. During sleep his breathing was so difficult that Dr. Thomas who has reported the case found himself obliged to resort to surgical treatment for its relief. The result was successful. The mode of procedure adopted is interesting as bearing upon the performance of an operation requiring some delicacy of manipulation. As was to be expected, a small, specially constructed forceps was employed and a piece of vegetation was detached by a single effort, no more being done on each occasion. The process was repeated at intervals of a week and after three sittings the nasopharynx was clear. In order to avoid injuring the vomer—the chief danger to be guarded against—particular care was taken to direct the forceps upward and backward. In most cases of adenoid overgrowth in infancy medical treatment happily suffices to relieve symptoms and postpone the need of operation. Dr. Thomas's experience is suggestive in connexion with those rare cases which call for active surgical measures as proving what may be accomplished by patience, tact, and gentleness.

THE NEW SCHOOL BUILDINGS OF MIDDLESEX HOSPITAL.

SIR CHARLES BELL in 1836 wrote: "We have founded a school in the garden of the Middlesex Hospital. The building will be a complete little thing. ...... You cannot imagine a prettier thing than that school." What would he say if he could see the new buildings of the school to which his name did so much honour? These consist of two blocks, one facing the hospital garden and the other facing Union-street. On the ground-floor of the first block a vestibule leads into a room for instruction in public health and a room for the official work of the school, while it also opens into the large lecture-room and the museum. From this vestibule another door opens into a series of rooms for chemistry; a large laboratory, a lecture-room, and a private room for demonstrators or lecturers beyond. The laboratory (for organic and inorganic chemistry and for sanitation work) will accommodate 35 students; the lecture-room will hold 50. On the first-floor are the pathological rooms; a very large laboratory for general practical work, and for lectures, a bacteriological laboratory for advanced or research work, and the pathologist's private room; beyond this a suite of rooms communicates with the post-mortem room. The mezzanine floor contains the anatomist's room and a dark room for photographic work. The anatomical rooms, three in number, are in the basement and are connected by an electric lift with the dissecting room on the top floor. The dissecting room, 75 feet long, is warmed with hot water, ventilated with electric fans, and lit from above and also by moveable pendants of electric light. The floor is of terrazza stone, the tables are of glass, and the walls are panelled with slate for diagrams. On the same floor are the demonstrator's private room and a large room for the practice of operative surgery. The Union-street building is given over to physiology. On the ground-floor are three rooms, one for making quantitative analyses, another for independent work, and a third large room for general class purposes. On the first floor there is a very large room for practical work and the physiologist's private room, containing a small dynamo, whence a shaft will run the whole length of the workroom, supplying motor power to revolving cylinders. Briefly, it would be difficult to devise a better set of buildings for their purpose. Every detail has been thought out, every latest improvement has been added to make them as perfect as possible. It may be mentioned that in connexion with the inauguration of the new buildings Dr. Frederic Hetley, J.P., D.L., a former student, has generously contributed the sum of £1000 to perpetuate the "Hetley Clinical Prize" of £25 per annum founded in 1884.

EARLY DIAGNOSIS OF CANCER OF THE LUNG BY MICROSCOPICAL EXAMINATION OF THE SPUTUM.

AT the meeting of the Société Médicale des Hôpitaux on Jan. 13th M. Paul Claisse called attention to this means of diagnosis. A man, aged 50 years, habitually in excellent health, began to waste. One day he expectorated two little greyish-white fragments almost of the size of a cherry-stone and with irregular surfaces. Examination of a section showed epithelial tissue composed of unequal elements, in places cubical, in others arranged concentrically like epidermic nodules. It was concluded that the fragment was of pulmonary origin and epitheliomatous. At this time no signs of disease could be found in the lungs. After several weeks the diagnosis was confirmed, in particular by the appearance of currant-jelly expectoration. In a second case in which the diagnosis was already certain the fragments were too small or too necrosed for thorough examination, but their presence at least showed that they belonged to a pathological tissue. M. Claisse pointed out that without systematic search the fragments might escape observation and be mistaken for inflammatory or alimentary products. As the diagnosis of pulmonary cancer is often difficult at the beginning this means of diagnosis is valuable.

HETEROCHROMOUS EYES.

"IN a family I am attending," writes a correspondent, "there are three children. In the eldest and youngest (who are boys) the right eye is hazel and the left eye blue. In the second child (who is a girl) the right eye is blue and the left hazel. The father has blue eyes and the mother has hazel eyes." The condition recorded is uncommon but not extremely rare. Two forms of heterochromia are recognised by ophthalmologists—one, in which one eye only is parti-coloured, a segment of the iris being of one colour and the remainder of another colour, a condition named "heterochromia unilateralis"; the other, in which as in this case the iris of one eye is different in colour from that of the other, named "heterochromia bilateralis." The dark colour of the iris in the southern nations and in the yellow races, as in the Chinese, is due to pigment in the superficial cells and in the cells of the stroma. The blue iris chiefly observed in the northern nations is due to the absence of pigment. Very dark irides are seen in the descendants of the Jutes in the Isle of Wight and, according to MM. Truc and Vallude, in Bristol and in Hainault in Belgium, whilst the blue iris is not unfrequent in Upper Italy, amongst the Basques, and even exceptionally in Morocco and Tunis. In France Topinard recognises two zones, the north-east with light-coloured or blue irides, and the south-west with brown eyes. It is not correct to say that all infants' eyes are grey at birth. We have seen them of a very dark colour. It has been thought that eyes presenting a difference in colour in their irides are not perfectly developed and that any operation upon them should be undertaken with some hesitation and reserve, but it does not appear that there are any statistics bearing upon the question. *The influence of heredity* on the colour of the eyes has been shown to be marked. When both parents have blue eyes, or both parents dark eyes, about 95 per cent. of the offspring have irides of corresponding colour, but when one parent has blue and the other dark irides the number of dark and light irides in the children is about equal.

SCHOOL EDUCATION AND NEEDLESS INJURY TO CHILDREN.

WE have received a copy of an address on the above subject delivered by Dr. Clement Dukes before the meeting of headmasters held in London on Jan. 13th and 14th of the present year. It is a powerful indictment of the abominable cast-iron system of present education. It is not the great public schools such as Westminster, Winchester, and Eton which are so much at fault as Board schools and so-called voluntary schools. "This," says Dr. Dukes, "is what prevails. In the 'infant schools' where the ages range from three to seven years the morning hours of work occupy from nine to 12 with a break of a quarter of an hour; and the afternoon lessons from two to four. ...... Children of three years of age are kept at lessons indoors five hours a day *for five days* a week." Attendance is not compulsory before the age of five years, but yet "schoolroom and teacher are provided ...... and attendance is courted for the sake of the Government grant." We have no hesitation in saying that the system is extravagant, cruel, inefficient, and hurtful to the health of the coming generation. In addition, far too many subjects are taught. Years ago Kingsley wrote as follows concerning the turnip in the Examination Island: "Can you tell me anything at all about anything you like?" "About what?" says Tom. "About anything you like, for as fast as I learn things I forget them again, so my mamma says that my intellect is not adapted for methodic science and says that I must go in for general information." We commend this passage to the Education Department.

LARGE FRAGMENTS OF AN EPITHELIOMA OF THE STOMACH EXPELLED BY VOMITING.

THE size of the fragments expelled in the following case, related by M. Mathieu at a recent meeting of the Société Médicale des Hôpitaux, is remarkable. Microscopic examination often enables the diagnosis of cancer of the stomach to be made by the detection of *epitheliomatous structure*; more rarely fragments are recognisable by the naked eye. A man, aged 58 years, had increasing dyspeptic symptoms for six months. Appetite disappeared and he lost 30 lb. in weight. He had acute pains in the pit of the stomach and abundant vomiting. In the vomited matter the food taken on the previous day or on the day before that was recognised. The vomiting had ceased for six or seven weeks when with a small quantity of the gastric contents he expelled some hard masses. On examination a rounded tumour was found a little below the xiphoid cartilage. The fragments after lying eight days in alcohol consisted of three whitish-yellow masses marbled with reddish purple from infiltrated blood. They were elastic and had a fibrous structure. They showed traces of rupture and where entire little mammillated projections. The largest fragment was two inches in length and a third of an inch in diameter. It had the appearance of an adenomatous or epitheliomatous vegetation torn away at the hilum. The three fragments together weighed two drachms. Microscopic examination showed areolæ separated by connective tissue and lined with cylindrical epithelium—in short, almost the structure of a polyadenoma or cylindrical epithelioma. As the patient had for some time vomiting denoting dilatation of the stomach with stasis, and as this vomiting disappeared, the question arose, Might not the separation of such vegetations have caused disappearance of the stenosis of the pyloric orifice? In analogous conditions signs of pyloric insufficiency have been seen to succeed those of stenosis. A somewhat similar case was reported by Dr. W. O'Neill in THE LANCET of Oct. 3rd, 1896, in which the weight of vomited cancerous tissue was between eight and 10 ounces.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

AT the annual general meeting of the society held on March 1st, the President, Mr. Thomas Bryant, being in the chair, the report of the council, showing a satisfactory financial position, was presented. The unusually large number of 35 new Fellows had joined the society. The President delivered the annual address and according to custom gave short biographies of those Fellows who had died during the year, dwelling with especial fulness on the careers of Sir Richard Quain, Dr. Charles West, Mr. Henry Lee, Sir William Jenner, Dr. C. J. Hare, and Professor Kanthack, and a hearty vote of thanks was awarded to him. A cordial vote of thanks was also given to Dr. Norman Moore who is retiring from the post of honorary secretary, after having held it for three years. The following gentlemen were elected to hold office for the ensuing year:—President: Mr. Thomas Bryant. Vice-Presidents: Dr. George Fielding Blandford, Dr. Samuel Jones Gee, Mr. Henry Greenway Howse, and Mr. Reginald Harrison. Honorary Treasurers: Dr. William Selby Church and Mr. J. Warrington Haward. Honorary Secretaries: Dr. Thomas Barlow and Mr. Alfred Pearce Gould. Honorary Librarians: Dr. Norman Moore and Mr. Rickman J. Godlee. Members of Council: Dr. Francis Henry Champneys, Dr. Stephen Mackenzie, Dr. Seymour John Sharkey, Dr. Eustace Smith, Dr. Francis Warner, Mr. W. Bruce Clarke, Mr. George Henry Makins, Mr. Robert William Parker, Professor Edward Albert Schäfer, F.R.S., and Mr. Edgcombe Venning.

PLAGUE IN MADAGASCAR.

THE circumstances of the occurrence of plague in Madagascar are described in much detail in a first report compiled by Dr. Lidin, presented to the Governor-General, and published in the *Journal Officiel de Madagascar et Dépendances* of date Jan. 10th, where it occupies a space exceeding five pages of THE LANCET. Dr. Lidin, who is principal medical officer with the army of occupation, states that on Nov. 23rd, 1898, the Administrator of Tamatave was informed by Dr. Chevreau (a civilian practitioner) that several suspicious deaths had taken place among natives employed by his European patients. Next morning Dr. Sallebert of the military hospital, after an examination of patients and of some dead bodies, pronounced them to be cases of plague and on Nov. 26th Dr. Clouard found the plague bacillus in abundance. Quarantine was immediately established. Tamatave is a seaport; the habits of the population who number about 7000 are extremely insanitary. Evidently the disease had existed for some time before it was recognised by Dr. Chevreau; Dr. Lidin considers that its origin must be dated back for six weeks at least, but perhaps not much more, and that it was imported by means of bags of rice brought from India. Infection from one person to another was at first not well marked, for it often happened that a death in a cottage occupied by several persons was not followed by other cases among the survivors; after a time, however, attacks occurred the origin of which could not be traced and the disease became generalised. From Nov. 24th to Dec. 14th there were 114 cases discovered, including only three Europeans, and during the same period there were 73 deaths. The European patients were a lady who gave birth to a child during her illness, a sailor in indifferent health, and an elderly German governess. The last died, the two others recovered. Other parts of the *Journal* give the later information that on Jan. 6th there were three fresh cases with three deaths, and on Jan. 7th six fresh cases with six deaths. On Dec. 31st the Governor-General issued an order directing that all possible steps should be taken to destroy rats and mice by trapping them or by laying down phosphorus, arsenic, or strychnia mixed with breadcrumbs, meat, cheese, or fried bacon. Fleas also were to be destroyed by watering the floors with boiling water or solution of corrosive sublimate, or by applying wax mixed with petroleum. Personal cleanliness and general hygienic measures were also specially enjoined.

PARALYSIS FOLLOWING CEREBRO-SPINAL MENINGITIS.

IN the *Boston Medical and Surgical Journal* of Feb. 16th Dr. W. N. Bullard calls attention to certain forms of paralysis occurring during cerebro-spinal meningitis and persisting after the acute stage of the disease. They differ from the ordinary forms and do not entirely correspond to other forms which are described. All the cases occurred in children. In certain stages they resembled cases of anterior poliomyelitis, but they differed in the following respects. Pain on passive movements persisted to a degree rarely if ever found in anterior poliomyelitis. Such pain and tenderness may exist during the acute stage of the latter for two or three days, but if it lasts longer than a week the diagnosis is to be questioned. On the other hand, not uncommonly in cerebro-spinal meningitis great pain on passive movement, especially of the ankles, may exist two or more months after the acute stage. Tenderness of the muscles also persists longer. There is always a tendency to spastic contracture. The knee-jerk on the whole is less affected, but it may be abolished. In addition to these signs the history of the attack is a guide.

THE ROYAL MEDICAL BENEVOLENT COLLEGE, EPSOM.

BOTH the educational and benevolent sides of the work that is carried on at Epsom College have always received from us our best support, for we not only know the measure of good that is done but we realise the enormous extent of the good which might be done if anything like adequate assistance or the assistance that might be expected were received from the medical profession and the public. To add in some way, however small, to the success of the Royal Medical Benevolent College at Epsom is, in our opinion, something like a duty incumbent upon every medical man. Those to whom the act of contributing is no burden should give freely for the good of their poorer brethren and these should give what they can. No man can certainly foresee and guard against all the insidious attacks of misfortune or gauge how soon those near and dear to him and dependent upon him may need the helping hand which this institution extends to both widow and children. We feel sure that the lack of support of the College by medical men as a whole, which we have often had to deplore, is not due to apathy alone but partly to the fact that the profession realises neither the good which the College already does nor its potentialities for better things if it were adequately supported. If medical men appreciated the work at Epsom at its *proper* worth they would support the College more generously themselves and would take advantage of their many opportunities of bring to the notice of their wealthy patients the claims which the institution has upon the public. As a correspondent in another column pertinently asks: "How many practitioners sacrifice their lives in the service of the public before they have had time to save?" If laymen understood how large this number is we do not believe they would be slow in their attempts to repay their benefactors. Dr. Holman, the honorary treasurer, is asking for aid in collecting the £6000 which he has to find each year for the Council to spend on the aged pensioners and foundation scholars. "If each member of the medical profession," to use the words of a former appeal, "would send 10*s*. to the hon. treasurer or even 5*s*. a year for a few years the position of the pensioners and foundation scholars would be placed on a secure financial basis and the council would be able to improve the school and extend its useful influence still more." Who among the poorest in our profession could not give just a trifle, and how many are there who would miss 10*s*. or even more?

Dr. W. H. Corfield, medical officer of health of St. *George's*, Hanover-square, has written to his vestry pointing out that while for several years (with the exception of 1897) there have been more cases of enteric fever in the parish per month during November and December than during the preceding three months, and while this disease has been unusually prevalent and fatal in London during the last three months, November, December, and January are not the months for the "seasonal prevalence" of this disease. Dr. Corfield thinks, therefore, that some other cause for the excess of it must be sought for and it may be something more than a coincidence that in those very months London is supplied with water which, according to Sir Edward Frankland's report, contains "an excess of organic matter."

The next examination for the certificates in nursing and attending on the insane issued under the auspices of the Medico-Psychological Association of Great Britain and Ireland will be held *on Monday, May 1st*, 1899. Candidates should obtain from the Registrar (Dr. Spence, Burntwood Asylum, near Lichfield) a *schedule, to* be filled up, signed, and returned to him at least four weeks before the date of the examination. Monday, April 3rd, will be the last day upon which, according to the rules, candidates can enter their names for the May examination.

We have again to congratulate University College, Liverpool, upon noble accessions to its funds. At a complimentary banquet at the town-hall to Professor Oliver Lodge, in recognition of his having received the Rumford medal of the Royal Society for 1898, Principal Glazebrook was able to announce donations of over £15,000 towards the estimated sum of £30,000 required to equip a proper physical laboratory for Professor Lodge.

The Senatus Academicus of Edinburgh University have resolved to confer the honorary degree of LL.D. upon William Mitchell Banks, M.D. Edin., F.R.C.S. Eng., Professor of Anatomy in University College, Liverpool.

Mr. Alfred Cooper, who has been on the active staff of St. Mark's Hospital for upwards of 34 years, has been elected honorary consulting surgeon on his retiring *from the position* of surgeon.

Mr. F. G. Parsons, F.R.C.S. Eng., delivered a course of three lectures upon the Joints of Mammals compared with those of Man at the Royal College of Surgeons of England, the dates of delivery being March 6th, 8th, and 10th. In the first lecture the temporo-maxillary articulation, together with those of the shoulder girdle, were dealt with, and in the second the joints of the elbow, wrist, and hip.

The Senatus *Academicus of Aberdeen University* have resolved to confer the honorary degree of LL.D. upon James *Frederick Goodhart*, M.D. Aberd., F.R.C.P. Lond., consulting physician to Guy's Hospital; Charles Stewart, M.R.C.S. Eng., F.R.S., Conservator of the Museum of the Royal College of Surgeons of England; and George Frederick Stout, M.A., Lecturer on Comparative Physiology in Aberdeen University.

The Brighton Town Council decided without dissent at their last meeting on the unanimous recommendation of the sanitary committee to increase the salary of Dr. Newsholme, medical officer of health, from £800 to £1000, which shows that the Brighton Town Council appreciate two good things—a clean public health bill and a medical officer who knows how to keep it clean.

At a meeting of the weekly board of St. George's Hospital held on Wednesday, March 8th, it was unanimously resolved, on the recommendation of the medical staff, that in future contracts for milk a clause should be inserted providing that milk should be supplied only from animals which have been duly certified to be free from tubercle.

Mr. Frederick Treves, consulting surgeon *to* the London Hospital, has been appointed an Emeritus Professor of Surgery to the London Hospital and will give a course of lectures in clinical surgery in the winter session. The special subjects and dates will be announced in due course.

We understand that owing to the lamented death of Professor Kanthack a session of the Summer School of Medicine at Cambridge cannot be held this year as was intended. It is hoped that arrangements may be made to hold another session in 1900.

Professor Burdon Sanderson, F.R.S., Professor of Medicine in Oxford University, will give the Croonian Lecture before the Royal Society on *Thursday*, March 16th. The subject will be the Electrical Concomitants of Motion in Plants and Animals.

The death is announced of Mr. Francis Nottidge Macnamara, M.D. St. And., M.R.C.S. Eng., at the age of 67 years. Deceased was formerly in the service of the Honourable East India Company and was a prominent authority upon tropical medicine.

The Council of the British Association have nominated Sir William Turner, President of the General Medical Council and Professor of Anatomy in the University of Edinburgh, to be President of the Association when it *meets in* Bradford next year.

The annual dinner of the Medical Society of London was held on Wednesday last, March 8th. The unfortunate indisposition of our representative prevents us from giving a full report this week.

The late Professor Rutherford has bequeathed to Edinburgh University his valuable medical library and his physiological and microscopical specimens and diagrams.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE fifty sixth sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Feb 28th The Commissioners present were the Chairman (Lord Llandaff), the Right Hon J. W. Mellor, Sir John Dorington, Mr de Bock Porter, Mr Robert Lewis, and Major-General Scott The witnesses examined were Mr Henry Gill (secretary of the Chelsea Water Company), the Right Hon Sir William Hart Dyke, Bart , M P. (chairman of the Kent Waterworks Company), and Mr Alexander Dickson (secretary of the Kent Company)

At the commencement of the sitting Mr RICHARDS, on behalf of the Chelsea Company, said that the secretary had searched the minute books and had found entries as to the arrangements which had been made between the Chelsea Company and the other metropolitan companies which were authorised to supply parts of the district within the statutory limits of that company

Mr GILL said that the minute books were very voluminous, but that he had found a transcript of the whole history of the negotiations which had been entered into between the Chelsea Company and the New River, the Grand Junction, and the West Middlesex Companies with regard to the partition of the areas These particulars, we believe, have not hitherto been published The extracts which were taken from the minute books were rather lengthy, and it may be sufficient to state that ultimately, after some preliminary skirmishing, a complete arrangement was made and signed by the directors of the boards of the companies interested and it was decided that a formal agreement should be prepared It did not, however, appear that any binding legal document had been entered into and Mr POPE, Q C , pointed out that in the report of the Parliamentary Committee which inquired into the London water supply in the year 1821 it was alleged that no formal agreement had been made with regard to the abolition of competition between the companies

The witness put in a statement showing the average supply per head per day in 11 of the districts in which Deacon s water meters are in use From this table it appeared that a considerable reduction had been made in the amount supplied since Deacon s meters had been used For example, in one district the average amount per head was reduced from 25 7 to 18 gallons per head daily and in another district from 39 5 to 19 5 gallons daily

In answer to Mr MELLOR the witness said that he attributed most of the waste which had formerly taken place to defects in the fittings of the customers of the company It did occasionally happen in times of frost that taps were allowed to run, but undoubtedly most of the waste was due to leakage of the taps It was possible to have fittings which were absolutely tight but the time which they lasted in a sound condition depended partly on the quality of the fittings, partly on the amount of use which they had, and very greatly on the manner in which they were used The districts in which the reduction had taken place contained a large number of new houses and the saving which had been made in consequence of a thorough examination of fittings had been very great

In answer to Mr MELLOR the witness said that the company had not yet introduced the Deacon meters into all parts of their district, but they were now trying them in places in which there were a large number of old houses

Sir JOHN DORINGTON pointed out that one of the witnesses had told them that it was cheaper to pump a sufficient amount of water to make up for the waste than it was to introduce a thorough method of inspection, and Mr POPE Q C , pointed out that in Glasgow they had never adopted Deacon's meters because they had an unfailing abundance of water, but of course where the supply was limited it was important that waste should be checked The supply to Glasgow was given by gravitation and the amount was practically unlimited

In answer to Mr MELLOR the witness said that they made an extra charge for automatic flushing tanks and the charge was calculated at the rate of 1s per 1000 gallons This charge was made even in the case of heavily rated houses for they found that in some cases tanks were emptied every hour and that an enormous amount of water "was wasted" in this way.

In answer to Mr MELLOR, the witness said that he did not think there was any necessity for these large tanks and that the frequent flushing was a modern sanitary requirement

Mr POPE on behalf of some of the metropolitan water companies called it "a modern fad"

The CHAIRMAN said that he was quite startled at the results which had been attained by the use of Deacon's meters but Mr PEMBER pointed out that even more striking results had been obtained at Oxford and at other places, and Mr LITTLER, Q C , stated that at Norwich the water supply had been reduced to 15 gallons per head daily.

Sir WILLIAM HART DYKE said that the customers of the Kent Company did not complain either of the quantity or of the quality of the water supplied by the company in which he was interested The Kent local authorities had been content to leave the supply in the hands of the company No effort had been made by any local authority under the Public Health Act to carry out a water supply for themselves At one time the local authority of Woolwich had a scheme but it was not put into operation, it was handed over to the Kent Company

In answer to the CHAIRMAN the witness said that he had heard nothing of any strong public sentiment in Kent to the effect that people wished to have the water supply in the hands of "representatives of the people"

The CHAIRMAN asked the witness to state his views with regard to the purchase of the undertakings of the Kent Company by some public authority The witness said that as representing a large industrial business it of course went without saying that the Kent Company did not wish to be disturbed, but should Parliament decide otherwise they would of course have to submit He did not contend that under no possible circumstances should a scheme of purchase be initiated Strong language did not help an argument, but he ventured to submit that purchase should be the last possible resort In saying this he spoke not only on behalf of the company but on behalf of the consumers and of the public For example, in the case of the Kent Company he thought that they had presiding over the destinies of the company a representative and strong directorate, a strong body composed not only of business men but of representative men, men who lived on the spot and who were connected with the interests of the consumers and with the county of Kent This body presided over a district of 187 square miles, including something like one fifth of the metropolitan area They had on their board a representative man, the Member of Parliament for a large constituency—that of Lewisham, a place situated right in the centre of their area of supply, a large and increasing district—a man whose name was a household word in the engineering world, one who had great experience in all matters concerning water supply who apart from his representative capacity, possessed a knowledge of engineering which was useful in examining estimates and in directing work of that sort in which special knowledge was useful Again, they had on their board Mr Henry Fowler, who had held high office in the State and who had been connected from his boyhood with municipal life The Lord Lieutenant of the county was also on their board The witness himself represented 16 000 electors in the county of Kent and these gentlemen would probably wish to know the reason at the next election should any failure take place in their water supply and, for his own part, he was determined as long as he held his position not to allow his political opponents the luxury of any solid criticisms with regard to the water supply of Kent

The CHAIRMAN asked the witness whether there was any sort of control which he could suggest which would be advisable It had been suggested that extensive pumping from the chalk was injuring private wells The witness said it was true that that suggestion had been made

The CHAIRMAN asked whether there would be any objection to have the wells gauged and the rest level taken and information of that sort given to the public The witness replied that in his opinion neither the company nor any other corporate body would lose by giving the fullest information to the public whenever there was a strong public grievance He would be opposed to too close supervision of their works or anything harassing to their engineers, but with regard to information to the public which they had a right to demand with reference to the question of lessening water in the rivers he thought the public ought to have it and he went so far as to say that they must have all reasonable information given to them.

The Chairman asked the witness whether he thought that the management would be as efficient and as economical in the hands of a public authority as it was at present, and the witness replied that it was possible that men might be found in the county who would be able to manage the undertaking of the Kent Company, but in his opinion there must necessarily be a loss to the consumers in the disturbance of what is good in regard to that management of to-day. For example, they had followed a fixed policy from year to year with regard to their future supply. Day by day and week by week the policy of the Board had been to look forward and to keep steadily in advance of the immediate needs of their customers. It was surely better to have men to manage such a business who had been all their lives at the work, who were connected with the district, who knew it by heart, who knew every pipe and every main in the district, as their engineer did, than to have new men embarking upon such a work. If they took away a man who knew it all by heart and put another man in his place whatever his abilities might be the water consumers would be the losers for years.

Mr. Mellor suggested that the purchasing authorities would employ the same engineer. The witness said that in that case it would be the same administration minus directors.

In answer to the Chairman the witness said that the Kent Company stood in an exceptional position with regard to the water—they were self-contained and independent.

The Chairman asked whether the Kent Company would be injured if some public authority bought up the other companies and left the Kent Company intact. The witness replied that there would be a difficulty with regard to their pumping stations, of which there were eight at present and a ninth in course of completion. Of these stations only two were in the metropolitan area.

The Chairman remarked that the undertaking was a large one and asked whether it would be in any way injured if it were left out of any scheme or purchase and continued to supply the same intra- and extra-metropolitan districts as it supplied at present. The witness replied that he thought that this would do no injury to the Kent Company.

Mr. Alexander Dickson in answer to the Chairman said that if it were necessary that a transfer of the Kent Company's undertakings should take place he thought it should be done either by agreement or by arbitration under the Lands Clauses Act. In the course of his examination the witness put in a table giving a summary of the increases and decreases of water rates upon alterations in the rateable values by the local authorities for the ten years 1887 to 1896. A table was also given showing that the increase in the rate valuation list totals was largely due to increases in the assessments of public companies. It was seen from these tables that in the seven larger metropolitan parishes of the company's district while the total increase upon the rate valuation of all properties amounted to £90,915 no less than £84,365 of this sum arose from the increased assessment on the properties of the public companies, the companies being railway, gas, water, and tramway companies.

The fifty-seventh sitting of the Royal Commissioners was held at the Guildhall, Westminster, on March 6th. The Commissioners present were Lord Llandaff (the chairman) Sir John Dorington, Mr. de Bock Porter, Mr. Cripps, Q.C., Mr. Robert Lewis, and Major-General Scott. The witnesses examined were Mr. Alexander Dickson, Sir Frederick Dixon-Hartland, Bart., M.P. (chairman of the Thames Conservancy Board), and Sir Edward Frankland, K.C.B., F.R.S. (water analyst to the Local Government Board).

Mr. Dickson in answer to the Chairman said that the existing sources of supply and the present pumping capacities of the Kent Company allowed them to distribute 16,250,000 gallons of water daily. Of this amount 4,000,000 gallons were supplied to the districts outside London. Within the county of London the company could obtain from 8,750,000 gallons daily, but they distributed 12,000,000 gallons. The sources of supply outside the London district were, therefore, more than sufficient for the rural parts of Kent, whereas the sources of supply inside the county of London were less than the amount needed for the supply of the metropolitan part of the company's district. This fact would cause a difficulty in case of any severance of the company's supplies between the county of Kent and the London district. The rural authorities in the county of Kent had not exercised the powers which they possessed under the Public Health Act but were content to be supplied by the Kent Company. The history of the company showed a gradual extension, new districts having been added to the company's area at the request of the rural authorities concerned. (The history of these extensions has already been given in The Lancet of April 3rd, 1897, p. 976.) The Sevenoaks Sanitary Authority had requested the company to supply water to a part of their district and Kent had, in fact, shown "anti-municipal" water tendencies. The county as a whole had been in favour of the unification of the water-supply in the hands of the company. Very few complaints were received from the customers and it was always found that any complaint with regard to the quality of the water was due to the arrangements in the consumer's own house. For example, a complaint had lately been received from Blackheath with regard to the quality of the water. An inspector of the company called on the morning on which the complaint was received and found that a starling in an advanced state of decomposition was contaminating the cistern which was placed in the roof of the customer's house. All the complaints which they received were due to local and accidental circumstances of this kind.

In answer to the Chairman the witness said that the different parts of the district were connected by mains which enabled them to supply water from one district to another so that in the case of a breakdown assistance could immediately be obtained. A case occurred, for example, in 1898 in which an accident befel the pumps at Wilmington and a supply to that district was sent from other stations. With regard to the rest-levels of the wells the witness said that the company would have no objection to giving any information which was required by the Local Government Board but he did not think that they should give that information to private individuals because their business might be thereby prejudiced.

In answer to Major-General Scott the witness said that as an instance of this a private individual might start a brewery near a successful well which was in the possession of the company. He thought that the company ought to be able to obtain all the water which they required for the supply of the inhabitants of their district even possibly at the cost of draining the wells of all their neighbours. At the present time the average daily supply was 16,000,000 gallons and the maximum last year amounted to 21,750,000 gallons. They could, however, obtain 25,000,000 gallons daily with their present pumping power. The witness contradicted an assertion made by Mr. Cripps, one of the witnesses employed by the London County Council, who stated that the total possible yield daily in the Kent Company's area was 27,500,000 gallons. The witness put in a large number of statements relating to the present condition of the company. These included a full account of the pumping mains and of the service mains, statistics of the daily supply from the year 1839 downwards, and tables relating to financial matters. The witness said that the company had never entered into competition with any other water company. When the Kent Company was started they were compelled to buy up the rights of an existing company. Their water rents for part of their district were secured under Letters Patent which gave them the exclusive right of supplying water for a period of 500 years within the manors of Sayes Court and East Greenwich.[1] The charter giving these rights was secured by the Kent Company and is held by them to-day. It followed, therefore, that no competition could take place in these districts without an infringement of those Letters Patent.

With regard to the cost of collecting the water rents the witness said that some of the collectors obtained 3 per cent. and some 2½ per cent. In the case of some of the older collectors who were unable to do much work from advancing years the company reduced the extent of their work and gave an additional commission. This amounted to a superannuation payment. The normal rate of commission was 3 per cent., which the witness suggested might be compared with that of the Liverpool outside districts in which 4 per cent. was allowed to the rate collectors. In the case of purchase by the London County Council the witness thought it would be necessary for that body to have a staff of collectors, because a considerable amount of the water rents received were for supplies given by meter or for some special purpose, and in each case there was a proper charge and each demand had to be made out separately.

---

[1] The date of the charter is 1701.

In answer to SIR JOHN DORINGTON the witness pointed out that Sir Alexander Binnie, one of the witnesses employed by the London County Council, had made a mistake in the evidence which he gave with regard to the water rents charged at Bradford. The charges for the domestic supplies in Bradford are charged upon the gross value. The incidence of the charges levied at Bradford is therefore different from that in London.

In answer to the CHAIRMAN, the witness said that should it be necessary for the company to raise more capital he thought the sinking fund which was imposed with a view to the immediate purchase of the undertakings by some one body ought in fairness to be discontinued. It would not be fair that the customers in the rural parts of Kent should be prejudiced by a sinking fund which would prevent the company from realising the surplus profits which would lead to a lowering of the water rentals, for the money handed over to the Chamberlain of the City of London under the sinking fund clause would not be applied for the benefit of the people of Kent.

Mr. BALFOUR BROWNE, on behalf of the London County Council, proposed to call Mr. Howard Martin, a gentleman from Croydon, to contradict some of the evidence lately given by Mr. Wilkins, secretary of the Lambeth Company.

Mr. PEMBER, Q C, interposed and stated that Mr. Wilkins had made mistakes in some of the evidence which he had given As a matter of fact the lower charges for water which had been made in Croydon began in July, 1894, and the Lambeth Company had received complaints both as to the quantity and as to the quality of the water which they had supplied. Mr. Wilkins had also forgotten that subsequently in the month of October there was a meeting between the engineer of the Corporation of Croydon and the engineer of the Lambeth Company and that an arrangement had taken place to the effect that if the Lambeth Company maintained the reduction in the water rents the Corporation of Croydon would not interfere with the Lambeth Company in that part of the district in which they had already laid their mains. Mr. Pember therefore admitted that in consequence of what "might be called" fear of competition the water rents had been lowered by the Lambeth Company.

Mr. BALFOUR BROWNE pointed out that Mr. Martin was prepared to contradict a statement made by Mr. Wilkins that the Lambeth Company had taken from the Croydon Corporation the supply of 69 houses, and he pointed out that the fact was that a supply was not given by the Croydon Corporation on the undertaking that the water rents should be kept at the present level The Lambeth Company agreed to maintain the reduction of rents, and therefore the Croydon Corporation had not interfered with the supply. Mr. Balfour Browne added that Mr. Martin was also prepared to prove that the Croydon Corporation was not, as Mr. Wilkins had said, "at the end of their tether" with regard to water-supply. They had water from a new source, and though it was true at one time that they had warned their customers to be careful of their water they had never been really short, and they were now making provision for a future supply in large quantities. As Mr. Wilkins had withdrawn everything which he had said with regard to Croydon it was not necessary for him to call the witness who was ready to give evidence.

Sir FREDERICK DIXON-HARTLAND, in answer to the Chairman, said that the Thames Conservators had no objection to the water companies taking their authorised supply upon an average of six months instead of upon a daily average if it were done in such a way that the Conservators had command of the water, so that it should not happen that a small quantity only was taken when the river was full and a large quantity was taken when the river was empty The Thames Conservators were primarily a navigation authority and their great duty was to keep the channel of the river in a proper state. At one time during the summer of 1898 only 43,000,000 gallons passed in a day over Teddington Weir. This was a great disadvantage to navigation. The Conservators were afraid that if the companies were allowed to tak

instead of on a daily maximum

quantity when there was a

en in a dry season take an

would be very bad for

The CHAIRMAN said that it seemed ridiculous that millions of gallons of water should go down the Thames and that a sufficient amount should not be taken when the water was plentiful. The witness pointed out that the difficulty which the Conservators had was that the metropolitan water companies wished to take the water when there was only a very small quantity in the river. The Conservators wished to have powers of restriction so that the flow of the river should not be reduced below a certain amount, and they thought that a heavy penalty should be imposed if water were taken from the river by the water companies should they abstract more than they ought in a dry season. The witness said that it was possible to get an injunction from a vacation judge but it was not so easy as when the courts were sitting.

In answer to Sir JOHN DORINGTON the witness said that he adhered to the evidence given by one of the officers of the Board to the effect that the flow over Teddington Weir should be not less than 200,000,000 gallons daily and that all the members of the Board agreed to that estimate.

In answer to Mr. DE BOCK PORTER the witness said that they wished that amount to be an irreducible minimum unless the amount were reduced below it by nature. The Conservators wished the metropolitan water companies to increase the storage capacity of their reservoirs. At the present time the capacity was insufficient. The storage capacity of the water companies ought to be sufficient for a 90 days' supply.

In answer to Major-General SCOTT the witness said that at present the water companies had statutory power to take 130,000,000 gallons daily without reference to the amount of the flow of the river. The Conservators felt strongly that their duty was to look after the navigation of the river and they objected to have their Acts put on one side. They might be content that the water companies should take in a time of drought any amount of water short of that necessary for navigation.

QUACKS AND ABORTION:

A CRITICAL AND ANALYTICAL INQUIRY.

VII.[1]

IN THE LANCET of Feb. 25th we stated that a very large number of London and provincial newspapers continue to publish the advertisements of persons professing to sell abortifacients and that many of these are the advertisements of those persons from whom we purchased the pills and potions upon which we founded our series of articles under this heading. It is almost inconceivable that the editors and proprietors of newspapers should be unaware of the purport of these advertisements after the revelations made in the course of the prosecution of the Chrimes brothers and after the full analysis that we published of the wares and literature of this infamous trade. Many, indeed, may have doubted our statement as to the continuing of the traffic in these medicines, varying, as we showed them to vary, from full doses of savin to harmless aperients, but all sold as competent to remove the most "obstinate obstructions" to the menstrual flow, one of the compounds of savin, sold by a Birmingham chemist named Ottey, being boldly characterised by him as strong enough to "shift anything." It will be remembered that we quoted the case of Owen v. Greenberg to show that the advertising agent or editor who has contracted to insert such advertisements cannot be compelled to do so, but even the advertisements of Owen (or Allen or the Irristum Company) continue to appear. In order that there may be no question of the wide dissemination of the advertisements or of the accuracy of our own statements with regard to it we give below a list of newspapers in which advertisements have appeared during or since the month of February either of persons whose trade we have discussed in these articles (in which case we give the name of the advertiser referred to) or whose advertisements are so worded that pregnant women are likely to purchase their medicines for

they are in fact of an abor

or of persons whose trade pa

of Dec. 10th, 17th, 24th, and 31st,

1899, respectively

objectionable character that no advertisements of their goods should, in our view, have been inserted without full inquiry on behalf of the newspaper in question. We note that some of the worst advertisers at times modify their usual form of advertisement; possibly this may have been done to meet the views of the editors of individual journals. In this case we are of opinion that an editor on whom an objectionable or criminal advertisement is sought to be planted ought to reject it entirely and not insert it in an emasculated form, because, however disguised, it can only be intended as a means of putting the quack, whether a would-be abortionist or ordinary swindler, in communication with his victim. Among advertisements of which we note the occasional modification are those of Madame Frain who at times professes that her preparations are "purely medicinal and not of use for any unlawful purpose." As we were not able to obtain specimens of these in return for our postal order, and consequently did not analyse them, we do not mention her name in our list, but we note that she still advertises in many organs without any such saving clause, and with the usual testimonials as to obstinate cases cured after weeks of misery and helplessness, while it is clear that her trade could hardly pay for its advertising if it was exclusively devoted to the cure of menstrual irregularities unconnected with pregnancy.

In the list below the names following the names of the newspapers are those of advertisers to whom we have called attention in our articles. We shall be glad to forward copies of the articles to persons responsible for the appearance of the advertisements who may wish for further information.

ARMY MEDICAL REPORT FOR 1897.

FIRST NOTICE.

THE report of the Army Medical Service for 1897 which has just been presented to Parliament dealing with the health and sanitary condition of the army gives the average strength of European troops serving at home and abroad during that year as 198,294 warrant officers, non-commissioned officers, and men. In what follows we cannot do better than adhere very closely to the excellent summary afforded in the report itself, reserving for a future occasion the consideration of the report in more detail. The total number of admissions to hospital was 192,654, and the total deaths were 1871. The admissions represent a ratio of 971·5 per 1000 of strength, the deaths one of 9·35 per 1000 on a strength of 200,058, which includes detached men not shown in the returns received. There has been again a decline in the admission and mortality rates amongst troops serving in the United Kingdom during the year, both as compared with the previous year and with the average for the decennial period.

There was no special prevalence of eruptive fevers, except at Caterham where there was an outbreak of scarlet fever. The ratios of admissions and mortality for enteric fever are the same as in 1896 and slightly below the average ratios. About one-fifth of the admissions occurred in Dublin, in many of which the fever was not, however, contracted there, but was traced to defects in the barracks at Birr. Influenza was more prevalent than in 1896. The decline in venereal diseases, which commenced in 1886 and has continued practically without interruption ever since, was again observed in 1897, the greatest decrease being in primary venereal sores.

Passing on to the army abroad we find that at Gibraltar there was a marked increase in the admission for venereal diseases in 1897; and enteric fever, although below the average for this command, was also more prevalent than in the preceding year. At Malta, Mediterranean and other continued fevers had increased in prevalence, but many of these cases, as well as a number of cases of dysentery, were contracted in Crete, the statistics of the sickness among the troops serving there having been included in those of the Malta command. In Canada the health of the troops was very good. In Bermuda there was a somewhat increased prevalence of enteric fever, the amount of which, though much below the decennial average, was above that of 1896. We may remark *en passant* that in the prevalence of this form of fever Bermuda compares unfavourably with that of other commands and appears to call for careful local investigation into its causes. The ratio for venereal diseases was relatively low at this station. There was an outbreak of yellow fever among the European troops in Jamaica causing 16 admissions and 10 deaths. Continued and malarial forms of fever were unduly prevalent among the troops serving in the West Indies. Venereal diseases showed a very high admission-rate which has been more or less continuous since 1888. In South Africa the health of the troops was fairly good on the whole, but enteric fever and dysentery caused a considerable amount of sickness in Natal. In Mauritius the health of the troops generally was above the average, the amount of malarial disease, which is *par excellence* the disease of that station, having decreased of late years.

In Ceylon there was little sickness of a special character. In China the most marked feature was the continuous and exceptional prevalence of venereal diseases which showed a further increase, amounting to nearly 33 per cent. in excess of the admissions during the previous year. In the Straits Settlements there was a large amount of sickness from malarial fevers, but venereal diseases declined considerably as compared with 1896 and with the decennial average. In India there was an increase in the admission and constantly sick rates, largely due to malarial fevers, and there was also an increase in sickness from enteric fever, other continued fevers, and cholera. There was a small decrease in venereal diseases. These diseases accounted for one-third and malarial fevers for nearly one-fourth of the total number of admissions. There were a few cases of plague among the troops in the Bombay command. The admission ratio of the troops in Egypt was lower than in 1896 and much below the average rate, the most notable decline being in enteric fever, venereal diseases, and digestive disorders.

AN HISTORIC CRISIS IN THE MEDICAL SOCIETY OF LONDON.

IN the course of some remarks made by the President of the Medical Society of London (Mr. Owen) at the anniversary meeting on March 8th, an account was given of a "lock-out" which occurred before the society was two years old. It happened thus:—

The first meeting of the society was held in May, 1773, at which 10 members were present, among them being Hulme, a retired naval surgeon, who was eventually the first librarian, Lettsom, the first treasurer, and Ford, who was asked to act as honorary secretary. Week by week new members were elected, amongst whom were John Millar, who shortly afterwards was voted into the presidential chair, Blizard and Bland, who successively helped Ford as secretary, and one, Pearce by name, who was, until he ceased to pay his rent, the society's tenant at their house in Crane-court. The part of this house which the society reserved for itself was the first floor, where, at a considerable cost, they had arranged a large meeting room and a small council room. Everything was going smoothly until the autumn of 1774, when considerable unrest occurred in connexion with the framing of rules. Party feeling ran high and the useful work of the society was seriously hindered. A special summons was sent out for a meeting of the society on Jan. 10th, 1775, for determining whether the report of the laws committee should be confirmed. This was decided in the affirmative by 17 votes to 13, three members not voting. In the minority were the president (Millar), the two secretaries, and the late secretary, Blizard. On the vote being declared the president and the secretaries resigned their respective offices but not their membership of the society. Now, the lease of the Crane-court house had been signed on behalf of the society by the president, the secretary (Ford), and the librarian (Hulme), and it, together with the minute books and the keys of the rooms, remained in their hands. On Jan. 18th, 1775, the anniversary meeting of the society was to be held, at which the officers for the ensuing year were to be appointed, but on the members repairing to Crane-court for that purpose they found the doors of their rooms "unwarrantably locked" and themselves without secretaries or minute-books. They adjourned, therefore, into one of the rooms which they had let to Pearce, where in considerable discomfort they elected their officers, with Lettsom at their head as president. The lock-out continued for a month, in the course of which it was reported to the Council that Millar, Ford, and Blizard had been heard to utter the impious statement that there was no such an association in existence as the Medical Society of London. Though by the action of their late president and secretaries the society had lost possession of its lease, its rooms, and its books, it considered that it had preserved its honour and its life, and the Council recorded their opinion that the impious expression given vent to by those gentlemen warranted them in erasing their names from the roll of its members. Meanwhile "*the Millar and his men*" had begun to realise the absurdity of the position in which their hasty act had placed them. If there were really no Medical Society of London what was the use to them of the lease which they had signed and impounded, and who was going to pay the rent of the house for which they had rendered themselves responsible? In these circumstances they sent Hulme, one of the co-signatories, as an ambassador to the Council, saying that if the Council would take over the lease and indemnify them from all future liabilities in connexion with it, they were willing to hand it over, together with the keys of the rooms and the minute-books. This the wise and gentle Lettsom undertook to do, and on March 7th, 1775, he had the great delight of composing a presidential message which was to be sent to all the members of the society "acquainting them that harmony is restored, and requesting their attendance as usual." At the same meeting the Council, doubtless at Lettsom's instigation, advised the society to consider "the Millar and his men" as members on their declaring themselves to be "friends of the society." This of course was don and as a proof that neither the society nor Lettsom bor Millar any ill-will for the very embarrassing and perilou course which, in the supposed interest of the society, he ha felt compelled to take, the society paid him the high compliment of asking him to deliver the Oration in January 1776. This also, it is hardly necessary to say, Millar wa glad to do, and it is very gratifying to see by the minute book that he had amongst his audience not only Hulme Bland, Blizard, and Ford, but Lettsom who occupied th presidential chair, and a large number of members wh must have voted against him on that momentous occasio twelve months previously. Fortunately, the good feeling amongst its members which carried the infant society safel through the convulsion and the crisis of 125 years ago stil prevails and shows no sign of diminution.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Withington Urban District.—The compulsory notificatio of measles was discontinued in this district during 1898, the council relying for their future knowledge of both measles and whooping-cough upon the public and private school authorities and on the school attendance officers. When a case of either of these diseases comes to the notice of the sanitary authority the inspector of nuisances will at once call at the invaded house and will leave printed instructions applicable to the case, and, if a medical man be not in attendance, this same officer will call at intervals to ensure the carrying out of the instructions. The inspector will also endeavour to make the notified cases clues to further and unnotified cases in the manner suggested by us recently in these columns. The day schools and Sunday schools involved will be notified of the cases and printed precautions will be left at houses near to the ones invaded. When five or more cases occur in connexion with any public school the average and present attendances in each department will be ascertained, as also the number of children known to be suffering from disease, and the number of children absent owing to the disease in question existing in their homes. When the number of actual cases either of measles or whooping-cough exceeds 10 per cent. of the average attendance in any department that particular department will be closed unless there should be strong contra-indications to such a course, and if a Sunday school is held in the same building a recommendation will be made to close this also. During 1898 the schools did not, Dr. Railton thinks, act as disseminators of either measles or whooping-cough.

Newton Abbot Urban and Rural Districts.—Mr. W. Harvey, in discussing the prevalence of enteric fever in the urban district during 1897, refers to two cases which, in his opinion, contracted their infection from the consumption of cockles, while a third person who partook of cockles at the same time was attacked with gastritis. Having regard to the interest which at the present time attaches to the question of infection by shell-fish it would have been helpful had the date of the cockle feast been furnished, as also some statement as to the condition in which the molluscs were when eaten—i.e., whether cooked or raw. The typhoid bacillus is, as is well known, killed at a lower temperature than boiling-point. Mr. Harvey also refers to two cases of typhoid fever which he regards as having had their origin in the ingestion of water while bathing. In the report as to the Newton Abbot Rural District Mr. Harvey refers to an outbreak of diphtheria which he thinks was associated with the local school, the disease disappearing on the closure of the school and recurring on its re-opening.

Buckingham Rural District.—Dr. Philip Benson states in his annual report that the council of this district have refused to put into action the Dairies and Cowsheds Order, and he expresses the opinion that the order should be made compulsory by the central authority. Doubtless Dr. Benson is here referring to the making of regulations under the Dairies, Cowsheds, and [illegible] the order itself is already obligatory upon sanitary authorities. He would like to see "all cows with diseased udders or otherwise found dangerous on inspection ...... got rid of," the owners being compensated. It is by no means satisfactory for Londoners to hear that in the Buckingham rural district, from which not improbably milk is sent to London, cowsheds, &c., are not properly controlled. Two villages in this district have recently been called upon by the Thames Conservancy Board to treat their sewage, and hence some progress in this direction has been made. Dr. Benson, however, has still to deplore the fact that there is no isolation accommodation other than a tent in this district, and he thinks that had the Buckingham County Council possessed a medical officer of health more progress would have been made. Buckingham is certainly not a progressive county as regards sanitation, although there is in this county such an abundant harvest awaiting the successful sanitary reformer.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6730 births and 4718 deaths were registered during the week ending March 4th. The annual rate of mortality in these towns which had been 19·5 and 20·6 per 1000 in the two preceding weeks further rose last week to 21·6. In London the rate was 22·1 per 1000, while it averaged 21·2 in the 32 provincial towns. The lowest rates in these towns were 13·1 in Croydon, 14·6 in Leicester, and 14·8 in Burnley; the highest rates were 25·3 in Preston, 25·4 in Birkenhead, 29·6 in Manchester, and 29·8 in Liverpool. The 4718 deaths in these towns included 437 which were referred to the principal zymotic diseases, against 340 and 364 in the two preceding weeks; of these, 117 resulted from whooping-cough, 109 from measles, 96 from diphtheria, 43 from diarrhœa, 40 from "fever" (principally enteric), and 32 from scarlet fever. The lowest death-rates from these diseases were recorded in Croydon, Brighton, Bristol, and Preston, and the highest rates in West Ham, Swansea, Birkenhead, and Manchester. The greatest mortality from measles occurred in West Ham, Derby, Manchester, and Salford; from scarlet fever in Sunderland; from whooping-cough in Plymouth, Swansea, Birkenhead, Bolton, Hull, and Sunderland; and from "fever" in Wolverhampton. The 96 deaths from diphtheria included 48 in London, 7 in West Ham, 7 in Liverpool, 5 in Swansea, 5 in Sheffield, 4 in Blackburn, 4 in Leeds, 3 in Portsmouth, and 3 in Leicester. No fatal case of small-pox was registered last week in any of the 33 large towns; and two small-pox patients were under treatment in the Metropolitan Asylums Hospitals on Saturday last, March 4th. The number of scarlet-fever patients in these hospitals and in the London Fever Hospital at the end of last week was 2584, against numbers declining from 2939 to 2575 on the nine preceding Saturdays; 236 new cases were admitted during last week, against 253, 202, and 241 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 413 and 484 in the two preceding weeks, declined to 470 last week, and were 87 below the corrected average. The causes of 69, or 1·4 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Salford, Newcastle-upon-Tyne, and in 13 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Preston, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns which had declined in the three preceding weeks from 31·2 to 24·1 per 1000 rose again to 25·1 during the week ending March 4th, and exceeded by 3·5 per 1000 the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 19·7 in Dundee and 24·4 in Aberdeen to 26·3 in Glasgow and 28·2 in Leith and in Greenock. The 765 deaths in these towns included 33 which were referred to measles, 31 to whooping-cough, 21 to diarrhœa, six to "fever," five to scarlet fever, and three to diphtheria. In all, 99 deaths resulted from these principal zymotic diseases, against 76 and 64 in the two preceding weeks. These 99 deaths were equal to an annual rate of 3·2 per 1000, which was 1·2 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had declined from 43 to 23 in the four preceding weeks, rose again to 31 last week, and included 11 in Glasgow, seven in Edinburgh, six in Leith, and five in Dundee. The deaths from measles, which had been nine and 19 in the two preceding weeks, further rose to 33 last week, of which 19 occurred in Aberdeen, seven in Glasgow, and five in Edinburgh. The six deaths referred to different forms of "fever" exceeded by two the number recorded in the preceding week and included four in Glasgow. The five fatal cases of scarlet fever corresponded with the number in the preceding week and included four in Glasgow; and of the three deaths from diphtheria two were recorded in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 285 and 233 in the two preceding weeks, further declined to 213 last week, but were 71 above the number in the corresponding period of last year. The causes of 52, or nearly 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin which had been 27·3 and 30·3 per 1000 in the two preceding weeks further rose to 31·9 during the week ending March 4th. During the past four weeks the rate of mortality in the city has averaged 30·3 per 1000, the rate during the same period being 21·4 in London and 26·2 in Edinburgh. The 214 deaths registered in Dublin during the week under notice showed an increase of 11 upon the number in the preceding week, and included 17 which were referred to the principal zymotic diseases, against eight and 12 in the two preceding weeks; of these, six resulted from "fever," five from whooping-cough, four from scarlet fever, two from diarrhœa, and not one either from small-pox, measles, or diphtheria. These 17 deaths were equal to an annual rate of 2·5 per 1000, the zymotic death-rate during the same period being 2·0 in London and 3·1 in Edinburgh. The deaths referred to different forms of "fever" which had been two and four in the two preceding weeks further rose to six last week. The fatal cases of whooping-cough which had been four and two in the two preceding weeks rose again to five last week. The four deaths from scarlet fever exceeded the number recorded in any week since November last. The 214 deaths in Dublin last week included 25 of infants under one year of age and 55 of persons aged upwards of 60 years; the deaths of infants showed a marked decline, while those of elderly persons slightly exceeded the number recorded in the preceding week. Eight inquest cases and eight deaths from violence were registered; and 90, or more than a third, of the deaths occurred in public institutions. The causes of 13, or more than 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

Royal Navy Medical Service.

THE following appointments are announced:—Staff Surgeon W. J. Colbourne to the *Boscawen*, additional for the *Agincourt*. Surgeons: H. Huskinson to the *Cambridge*, and G. B. Brown to the *Vivid*, additional.

Army Medical Service.

Surgeon-General H. S. Muir to be Deputy Director-General, vice Surgeon-General W. Taylor, C.B., who has vacated that appointment.

Royal Army Medical Corps.

Captains A. H. Bray and J. H. Rivers, and Lieutenants S. L. Cummins and H. G. F. Stallard are directed to proceed to Egypt for duty with the Egyptian Army. Major H. J. McLaughlin, half-pay, is posted to the Western Heights, Dover, for duty.

Army Medical Reserve of Officers.

Surgeon-Lieutenant Conrad Theodore Green, 1st Volunteer Battalion the Cheshire Regiment, to be Surgeon-Lieutenant.

Volunteer Corps.

Artillery: 1st Aberdeenshire: Surgeon-Major R. J. Garden resigns his commission; also is granted the rank of Surgeon-Lieutenant-Colonel with permission to continue to wear the uniform of the corps on his retirement. 2nd Sussex: Surgeon-Major H. Colgate to be Surgeon-Lieutenant-Colonel. 2nd Middlesex: Surgeon-Lieutenant A. B. Lyon to be Surgeon-Captain. *Rifle:* 17th *North* Middlesex: The under-mentioned Surgeon-Lieutenants to be Surgeon-Captains: P. S. Spokes and J. W. Fare. 1st Tower Hamlets: George Alexander Cohen to be Surgeon-Lieutenant. 1st Volunteer Battalion the Prince Albert's *(Somersetshire Light Infantry): Richard George Worger to* be Surgeon-Lieutenant. 4th (Cambridge University) Volunteer Battalion the Suffolk Regiment: The under-mentioned officer resigns his commission: Surgeon-Lieutenant G. V. Worthington. Galloway; Surgeon-Lieutenant D. D. Monro *to be Surgeon-Captain. 4th Volunteer Battalion the Hamp*shire Regiment: Surgeon-Lieutenant A. H. Vernon to be Surgeon-Captain. 4th (Stirlingshire) Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Lieutenant-Colonel M. Benny resigns his commission; *also is permitted to retain his rank and to continue to wear* the uniform of the battalion on his retirement.

THE EXAMINATION OF RECRUITS FOR THE ROYAL NAVY.

A correspondent sends us a copy of a circular which is sent out by the Medical Department of the Navy. It reads:

> Will you please inform me by return of post if you are willing to examine Recruits for the Royal Navy at —— on the following scale of remuneration—

(a) If a candidate is rejected by you	2s. 6d.
(b) If passed by you, but *rejected on medical grounds* at the final examination by a board of medical officers at the Royal Naval Hospital at the port	nil.
(c) If passed by you and not rejected on medical grounds at the final examination	4s. 0d.

Our correspondent asks us for our opinion on this scale of payment which he characterises as "sweating." At *first sight the scale may seem to be inadequate.* We understand, however, that the terms in question have been offered for some time and are those paid to the Admiralty surgeons and agents and marine recruiting officers throughout the country. *The fact that these appointments* are somewhat keenly sought after would seem to show that they are not considered inadequate. Our correspondent's complaint is the only one which we have as yet received with regard to the subject and we imagine that if the scale of payment was anything like universally regarded as "*sweating*" we should have heard more about it.

THE TRANSPORT OF SICK AND WOUNDED SOLDIERS.

We are glad to notice that the subject of our inadequate and defective arrangements for the transport of sick and wounded soldiers is receiving attention. This nation is lagging behind continental nations in this respect both in this country and in India. As regards the latter, the amount of railway accommodation requires to be in*creased and its quality improved for* the more comfortable transport of the sick and wounded towards Bombay and thence to England by troopship. The arrangements and accommodation for invalids on board ordinary troopships are not by any means all that they should be and we need a larger number of hospital ships, *designed and fitted out* as such, for the conveyance of sick and wounded men and invalids from abroad. *Sick soldiers returning from* abroad and suffering from the effects of malarious and tropical fevers or dysentery or invalided after active campaigning have a right to expect that they will be brought home in a roomy, comfortable sea going vessel where the medical, hygienic, and other arrangements *for their recovery are* made the main and not a subordinate consideration.

THE ABSENT HOSPITAL SHIP AND THE OMDURMAN CAMPAIGN.

We are not surprised that Colonel *Lonsdale Hale* is not at all satisfied with the further explanations of the Under-Secretary *of State for War in amplification of* those which he afforded the House of Commons on Feb. 16th. Mr. Wyndham was, of course, in no respect personally responsible in the matter; his task was to defend a grave mistake, to say the least of it, which had occurred before he was in office. There is no doubt that there should have been a hospital ship present at Alexandria, if not two; that there was ample time, if steps had been taken *to prepare one after it had been first* asked for by the Army Medical Service, to have had a hospital ship there; and that the want of it was sorely felt and prejudicially affected the interests of the sick and wounded.

RECRUITS.

According to the recently issued Report of the Inspector-General of Recruiting 66,501 recruits presented themselves for medical examination last year. Of these 23,287, or 35 per cent., were rejected for various ailments or for want of physical development; 13,969 for the first reason and 9318 for the second. *This is not calculated to afford a favourable* impression of the progressive improvement in the health and physique of those classes of the civil population from which recruits are mainly drawn.

THE OPERATIONS IN WEST AFRICA.

Among the names brought to the notice of the Minister *of War in the late despatch of the Secretary of State for the* Colonies are the following: Mr. E. H. Tweedy, Assistant Colonial Surgeon, Gold Coast; Dr. J. O. Coker, Assistant Colonial Surgeon, Gold Coast; Captain E. M. Hassard, Royal Army Medical Corps; Mr. W. H. G. H. Best, Assistant Colonial Surgeon, Lagos; and the late Mr. F. W. Rock, Assistant Medical Officer, West African Frontier Force.

THE SOUDAN.

The Khalifa's forces are stated to be raiding the districts and oppressing those tribes in the Soudan who were friendly to us during the late campaign and the impression is growing that a fresh expedition on a small scale against the Khalifa will be required. Meanwhile, the health of the British troops at Khartoum *is excellent and there is little or no fever* prevalent among them.

HONORARY SURGEON TO THE QUEEN.

We have to congratulate Surgeon-Major and Hon. Deputy Inspector-General J. Jee, V.C., C.B., half-pay, late Medical Department, on his being appointed Honorary Surgeon to the Queen, vice Surgeon-General Sir J. Mount, K.C.B., V.C., deceased.

DEATH IN THE SERVICES.

Surgeon-Major John Stuart Smith (retired), late A.M.D., on March 1st, at his residence in Edinburgh, aged 84 years.

Correspondence.

"Audi alteram partem."

THE PREVENTION OF PHTHISIS AND NOTIFICATION.

To the Editors of THE LANCET.

SIRS,—I have read with much interest the abstract of Dr. Newsholme's address published in THE LANCET of Feb. 4th, page 279; but while very much has been said of late about "The Prevention of Phthisis" I cannot feel at all sure that at this time there is sufficiently conclusive evidence to justify the doctrine.

As regards "notification" of the disease to the medical officer *of health, this will of course follow* when the *means* of diagnosis shall be certain and infallible. Possibly the *Local Government Board* may be able to arrange a *special* diagnostic department the officers of which would relieve us of much anxiety in cases in which the diagnosis was not quite certain and our patients of all doubt in a number of cases in which we feel unable to form what an actuarial friend of mine was always *demanding*—"a firm opinion." As I began medical teaching in 1850 I shall necessarily be called old, and perhaps a fogey or fossil in addition, but are we not going too fast and too far with regard to the "Prevention of Consumption" question? Nay, are we as yet justified in leading the public to infer that consumption *certainly can be "prevented" or "cured"?*

Everyone who has been *engaged for many years* in medical work in hospitals and among the more fortunate people who can command the "best advice of their time" has probably also seen many cases pronounced to be phthisis which were not of that nature—many cases in which the disease was not suspected or diagnosed in its early stages—and many more cases which were "doubtful" for a long time. I can *remember the cod-liver oil enthusiasm, the warm climate* enthusiasm, the open window treatment in high altitudes in midwinter. Other cases, again, in which great careers were needlessly cut short—cases in which money was wasted, and misery caused or much increased by steps being taken in consequence of "threatened tubercular disease," as well as sad cases which at first seemed to be "only a cold," but proved to be what we then called "acute phthisis" fatal in a few days or weeks. Of course such sad misfortunes would be no longer possible if in every case of phthisis the bacillus was detected, and was not present in any case in certain respects resembling the disease.

Then, as to the out-door treatment I would ask, Are there not hundreds of careful, intelligent members of our profession in suitable places in all parts of the country by whom doubtful cases might be watched for a time and serious cases efficiently tended — both classes of patients being happier, and chronic invalids better placed as to nursing, medical treatment, food and comforts than would be possible in hospitals, homes, or sheds, with strangers, hundreds of miles away? Lastly, there is the unfortunate proposal about "notification" and the imposition of yet more "laws"! Are we not already burdened with laws, inspections, orders, notifications and authorities with the right of disturbing us in our homes enough? Would *not* the public have been better off by this time had they been allowed to take advice from us, instead of being subjected to compulsory laws to be afterwards abrogated, left in abeyance, or neutralised by a "conscience" or other clause? If years ago vaccination had been left entirely in our hands and to our teaching and persuading powers, *would there have been at this time* a single unvaccinated or discontented person in the country? Of course I shall be told to look at Germany and her vaccination success—but the mental constitution of the German and the Briton is, indeed, very different. Perhaps from being less logical, we are not to be managed on precisely the same principles as those applicable to some of our foreign friends—especially where ideas of health and freedom are concerned.

I am, Sirs, yours faithfully,

Feb. 5th, 1899. LIONEL S. BEALE.

THE CENSUS BILL FOR 1901.

To the Editors of THE LANCET.

SIRS,—The Census Bill for 1901 being now under the consideration of the House of Commons it behoves all persons interested in vital statistics and sanitation (whether medical officers of health, practitioners, or members of the Statistical Society) to exercise their power in order to obtain a "Quinquennial Census" Bill instead of a "Decennial" one, also that the same be taken at the end of June. A quinquennial census is practised in France, New Zealand, Queensland, Manitoba, and North-Western Territory of Canada, and in some German States a triennial. Vital statistics must always furnish the basis on which sanitary reforms shall rest and as these are obtained from the population of districts, unless the said population is accurate the results desired, after the trouble of gathering the statistics, are worthless. Means have been adopted to obtain the estimated population of places for intercensal periods, but these are found to be inaccurate and the error increases the further the calculation is removed from the last census. The effect of migration is so great in this country and especially in rural districts, of which Cumberland, Westmorland, and Cheshire afford numerous examples, that no means can be adopted to cope with the same "except [illegible]requent census returns." Trusting that some of your [illegible]aders in each Parliamentary division will petition the [illegible]resentative of that division to support and vote for a [illegible]uinquennial census" when the Census Bill is before the H[illegible]se,

I am, Sirs, yours truly,

JOHN PENNY, M.B., B.Sc. (Public Health) Edin.

Great Broughton, near Cockermouth, Feb. 25th, 1899.

[INCLOSURE.]

(Copy of letter forwarded to each M.P. for Cumberland, Westmorland, and Cheshire by me.—J.P.)

THE CENSUS BILL FOR 1901.

Great Broughton, near Cockermouth,
March, 1899.

DEAR SIR,—The Census Bill for 1901 being now under discussion I take this liberty in writing to ask if you will kindly support a "quinquennial census" instead of a decennial one, also to have the same taken at the end of June. A quinquennial census is practised in France, New Zealand, Queensland, Manitoba, and North-Western Territory of Canada, and in some German States a triennial. Vital statistics must always furnish the basis on which sanitary reforms shall rest and as these are obtained from the population of districts, unless the said population is accurate the results desired, after the trouble of gathering the statistics, are worthless. Means have been adopted to obtain the estimated population of places for intercensal periods, but these are *found to be inaccurate and the error increases* the further the calculation is removed from the last census. The effect of migration is so great in this country and especially in rural districts, of which Cumberland, Westmorland, and Cheshire afford numerous examples, that no means can be adopted to cope with the same "except frequent census returns." Trusting you will do what little you can by speaking in favour of a quinquennial census when the Census Bill is before the House and voting for the same, I remain, yours, &c.

EPIDEMIC INFLUENZA: ITS PECULIARITIES AND TREATMENT.

To the Editors of THE LANCET.

SIRS,—The Thames Valley, like other parts of the country, has of late been suffering from an epidemic of influenza and an opportunity has thus been afforded us of studying the disease in its latest phases. The poison on this as on other occasions seems to be expending itself on the nervous system and though the cases are not usually serious they are very trying both to medical man and patient and exhibit signs of great prostration. It mostly manifests itself in two different forms. First, in neuralgic pains about the head and limbs; and secondly, in spasmodic cough similar to whooping-cough. It is somewhat curious to find that the temperature in these two forms is not as a rule identical. In the former it is usually above the normal, while in the latter it is below, generally only 97° F. As regards duration the first is, as a rule, much shorter than the second, but both are associated with great debility. As regards treatment, the neuralgic pains yield pretty readily to salicylate of soda, but the spasmodic [illegible] most undoubtedly a very difficult symptom to de[illegible], for as far as I have been able to see it is [illegible]d little or nothing by any treatment, whether gene[illegible] local. I have tried diaphoretics, nerve sedatives (su[illegible]s hydrobromic acid, prussic acid, conium, codeia, and [illegible]eminum), stimulants (as ammonia), tonic (as quinine an[illegible]ark), inhalations of steam (friar's balsam and cresyline), [illegible]d counter-irritation applied to the throat by means of chil[illegible] paste covered over with damp lint and oiled silk. Of all methods I think the last-mentioned is the best, supplemented with diffusive stimulants and bark.

I am, Sirs, yours faithfully,

Surbiton, March 6th, 1899. F. P. ATKINSON.

THE CLINICAL RESEARCH ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—As I am constantly receiving letters with reference to specimens sent to the Clinical Research Association for examination I should like to point out that I have never been on the staff of this body and, indeed, am not even a subscriber. By allowing this statement to appear in your columns you will save me considerable trouble in replying to letters about matters in which I am in no way concerned.

I am, Sirs, yours faithfully,

Cavendish-place, W., March 7th, 1899. J. W. WASHBOURN.

"HUNTER *v.* CLARE."

To the Editors of THE LANCET.

SIRS,—As there have been since the "Hunter case" statements and inquiries all seeming to cast doubt on the right of a Licentiate of the Royal College of Physicians of London to style himself "physician," I would reiterate the well-known answer given by the then Attorney-General, Sir R. Palmer, to a question submitted to him by the Royal College of Physicians whether their Licence conferred upon the holder the title of physician, the answer being in the affirmative. Secondly, that whatever may have been said by the way or in passing by the judges in the Hunter case or any inference therefrom is not authoritative, the only statements of a judge which are so authoritative being those which actually form part of the judgment on the question at issue. So I submit that the title of a Licentiate of the Royal College of Physicians is in no way altered by any *obiter dictum* or inference therefrom in the Hunter case.

I am, Sirs, yours faithfully,

Hastings, March 4th, 1899. FREDERICK W. COLLINGWOOD.

To the Editors of THE LANCET.

SIRS,—As I see that Mr. J. Noble Bredin of Potton has been accused of complaining to the General Medical Council of my late husband, I think it only right to state that the real complainant was another medical man, as can easily be proved. Beyond trying to get an honest living in that man's neighbourhood my poor husband never did him any harm, but the action which resulted from his complaint caused my husband's death at the early age of 31 years, leaving me completely unprovided for.

Mr. Bredin was a true and loyal friend to us both.

I am, Sirs, yours faithfully,
CAROLINE KINGSLEY HUNTER.

Warwick street, S.W., March 7th, 1899.

"SYMPTOMS OF POISONING FROM A SMALL DOSE OF TINCTURE OF CANNABIS INDICA."

To the Editors of THE LANCET.

SIRS,—I have been interested by reading in THE LANCET of Dec. 24th, 1898, the valuable observation on cannabis Indica by Mr. Antony Roche. I had a similar experience not long ago which might interest your readers. The patient, a young woman, aged 19 years, strong and robust in health, consulted me for dysmenorrhœa. I ordered her three-quarters of a grain of extract of cannabis Indica and added some camphor to it to be made into a pill. The next day her friends were alarmed by her condition and sent for me. I found that after taking one pill she was noticed to be different from her usual manner and the pleasurable intoxication of Indian hemp was present in a feeling of happiness and excitement. Soon, however, she complained of dizziness and went to sleep On awaking the next morning she was herself. The druggist assured me that no mistake had been made and that a similar preparation was sent to another person who took it without the least symptom of intoxication. I quite agree with Mr. Roche that some people are more susceptible to the action of the drug than others, in spite of the variation in strength of the official extract or tincture, and it would be better to begin with very small doses to test the patient's tolerance of it.

I am, Sirs, yours faithfully,
ANTONIUS J. MANASSEH.

Brumana, Beyrout, Jan. 10th, 1899

"REGINA *v.* REICHARDT."

To the Editors of THE LANCET.

SIRS,—Referring to Dr. Goodhart's remark, "I will not take up your space by discussing with Mr. Sers 'what constitutes insanity,'" I can assure this gentleman that I am better engaged on this occasion and have nothing whatever to do with the subject beyond what is involved in the legal aspects of the case. As I gather from Dr. Goodhart's letter he claims for certain privileged persons a kind of moral right to break the law—at least, he appears to see no reason why cases of temporary insanity should not be treated in uncertified houses; but if so, what is the use of legislation on the subject? The point I intended to bring before you is one of extreme simplicity. Dr. Reichardt, as I understand, received a patient suffering from some indefinite form of nervous disease which resulted in suicide. I submit therefore a *primâ-facie* case presented itself that the law was being tampered with. I say a *primâ facie* case was created to this effect and how could the case be decided on its merits without resorting to a court of law? The fact that the case had been seen by Dr. Savage, Dr. Goodhart, and Mr. E. C. Kingsford who pronounced it unripe for an asylum I further submit was not sufficient reason for deterring the Commissioners from taking legal proceedings, otherwise the administration of the law with regard to the control of insane persons would practically be at the caprice and mercy of private individuals; and although, of course, the *bona fides* of these gentlemen is unquestionable—and I say this with perfect sincerity—the fact of the case having been seen by the aforesaid gentlemen and considered unfit for an asylum is not sufficient reason for keeping the law in a state of inertia, otherwise there is no guarantee that on any future occasion men of equal integrity might be concerned and as an ultimate consequence of establishing such a precedent a refined system of covering or evading the law might be thereby created.

I am, Sirs, yours faithfully,
CLEMENT H. SERS.

Queen's road, Peckham, S.E., Feb. 18th, 1899.

THE ROYAL MEDICAL BENEVOLENT COLLEGE, EPSOM.

To the Editors of THE LANCET.

SIRS,—The appeal to the general public made by the treasurer of the Royal Medical Benevolent College at the end of last year appears to me to be well founded.

How many practitioners sacrifice their lives in the service of the public before they have had time to save. Dr. Holman asks for no help for the school, but urgently asks for aid in getting together the £6000 he has to find each year for the Council to spend on the aged pensioners and young foundation scholars. The appeal although addressed to the public in no way does away with the claims of this institution to the support of the profession. A perusal of the annual report tells a miserable tale of the scant support the College receives from medical men. Who can tell how soon misfortune may overtake a practitioner? Would it not be well even as a small insurance to subscribe to the College and thus to constitute a claim if necessity should arise to reap some of the benefits now offered but which might be so largely extended if money was forthcoming?

I am, Sirs, yours faithfully,
M.D.

"DIFFICULTIES UNDER THE NEW VACCINATION ACT."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 4th two gentlemen write on the above subject. One says: "Private practitioners have the game in their own hands. They have simply to take care that all their cases are vaccinated or accounted for to the vaccination officers before they are four months old." The second says: "Because your correspondent's patients and *themselves* [the italics are mine] do not comply with the law they try to make the public vaccinators answerable." May I ask what these gentlemen mean? It is, I think, the usual practice with private practitioners to vaccinate or sign postponement certificates only when the children are submitted to them. Both these gentlemen seem to imply that it is part of private practitioners' duty to either call upon the parents of such children as they have brought into the world without being sent for or to send them a reminder before the child is four months old as to the law on the matter. To take either of these steps would be offensive to most medical men, I think, and might lay them open to the charge of touting. Besides, it is no part of their duty and however the public vaccinator may be bound by the law the omission of these steps in no way justifies your second correspondent in saying that the medical attendant "has not complied with the law"; the parent may not have complied, but the new Act imposes no obligation whatever upon the medical attendant.

General practitioners have considerable justification for feeling sore on the point. Etiquette towards a professional brother is violated by visiting and "offering to vaccinate" his patient. It may be the law, but I should not care to carry it out and visit another man's patient in defiance of the ethics of the profession.

I am, Sirs, yours faithfully,
GENERAL PRACTITIONER.

March 4th, 1899.

To the Editors of THE LANCET.

SIRS,—Mr. T. F. I. Blaker must pardon me when I suggest that he has not quite grasped my argument and that that is why he finds my letter "silly." He simply begs the question when he justifies the public vaccinator as one "doing his duty." I say that to call on strangers and offer professional services is work that no professional man ought to undertake. It is only his "duty" inasmuch as he has voluntarily undertaken it. The medical officer of a canvassing medical aid society might as well plead that it was his "duty" to countenance canvassing and he might even say that the society was recognised by Act of Parliament. Parliament is no supporter of, but rather opposed to, our ethical laws. He must also pardon me for objecting to his suggestion that we must play the game by paying unasked visits ourselves and so defeat the public vaccinator. It is this very calling on people who have not requested our services that I think so undignified and unprofessional. Such visits would be very irksome to me, and I hope they will be so to all public vaccinators; that is all the "trouble" I wish these officers.

"Fairplay," in spite of his strongly worded opinion which is useless in an anonymous correspondence, gives away his side entirely. He says, "There is nothing interfering with professional etiquette if the law is complied with," clearly implying that if it is not complied with there is such interference. But it is the *parent's* duty to comply with the law; it does not in any way bind the private practitioner, so if through ignorance or neglect the parents do not comply with the law "Fairplay" practically confesses that the public vaccinator will act in a way "interfering with professional etiquette." That exactly expresses the view I hold. The truth is "Fairplay's" common-sense is too strong for his partisanship. His new reading of the 24 hour rule again allows his true opinion to escape. Of course it ought to be made clear to the public vaccinator that his services are desired before he calls, but in spite of his efforts to do so I am sorry to say "Fairplay" cannot read this into the Act. As to "Fairplay's" last argument, it would no doubt be unfair for a solicitor to abuse a policeman for arresting one of his clients, but I think he would justly blame a brother solicitor who so far forgot the dignity of his profession as to accept the duties of a policeman, and he would be still more indignant if he suspected that his rival was using the policeman's office to win clients. This is the true reading of "Fairplay's" analogy, and I believe he felt that the public vaccinator was playing the unworthy part of a policeman when he thought of the comparison. The schoolmaster is no analogy, for he does not and would not call upon defaulting children. "Fairplay" will not find an analogy in any other profession, for their members have too much self-respect to accept similar duties.

With apologies for such a long letter,

I am, Sirs, yours faithfully,

March 6th, 1899. P. P.

OXYGEN IN PNEUMONIA.

To the Editors of THE LANCET.

SIRS,—Now that the calamity which loomed over the English-reading world is happily no longer formidable, may I as an old-fashioned practitioner of medicine be pardoned for asking the following questions? 1. What proof is there that crude oxygen when used as a remedy in pneumonia ever reaches the blood? 2. Assuming that an augmented intake of oxygen leads to an increased absorption, would not a similar end be gained by directing the patient to respire in double quick time, after the manner recommended some years ago as a universal panacea by General Drayson, R.A., in the *Nineteenth Century Magazine?* 3. Is it not possible, or even probable, that in pneumonia artificial oxygen should act as a direct irritant on the unaffected portion of the lung tissue, thus favouring the spread of the inflammation and prolonging the duration of the disease? 4. Can it be that oxygen in lung affections will turn out to be one of those remedies to which a distinguished physician referred when he was recommending his pupils to be sure and make use of them while they were still capable of effecting cures?

I am, Sirs, your obedient servant,

March 3rd, 1899. A RETIRED SURGEON.

*** The use of oxygen in pulmonary affections—e.g., bronchitis—is by no means new. It was employed by Dr. (afterwards Sir) B. W. Richardson more than twenty years ago.—ED. L.

EXETER DISPENSARY.—The annual meeting of this institution was held on Feb. 28th under the presidency of Mr. A. J. Mackey. The report stated that 6144 cases had been treated during 1898, being a decrease of 174 on the preceding year. The financial statement showed that legacies to the value of £1970 had been received and that a favourable balance of £38 remained. A discussion occurred as to the advisability of increasing the area of the home-visiting of patients by the medical staff. Dr. Davy gave attention to the fact that all the medical staff [illegible]ary and recommended that a salaried medical of[illegible] should be appointed to visit patients. On the motion of Canon Hobson it was decided to refer to the committee the advisability of Dr. Davy's suggestion.

THE BATTLE OF THE CLUBS.[1]

(FROM OUR SPECIAL COMMISSIONER.)

WESTON-SUPER-MARE (*concluded from p. 621*).

ONE of the general practitioners at Weston-super-Mare explained to me that some 14 years ago he came to this town, having bought a small practice estimated at £300 a year. This practice included the post of medical officer to the Liverpool and Victoria Legal Friendly Society. At that time he was quite ignorant as to what this sort of work involved, but when he found out he at once began to agitate against such a system. His employers thereupon selected another medical man in the town and transferred all the members of the Liverpool Society to him. In a very short time, however, their new medical officer likewise rebelled against their mode of procedure, so the Liverpool Society imported another medical man into the town. This their third officer failed to give satisfaction and the society was now obliged to advertise for someone to replace him. In answer to this advertisement they got a fourth medical man, but he only stayed three weeks, and then they had to advertise again. This time they got "a strong man," but they seem to have "caught a Tartar." This the fifth medical man who in a very brief period had been engaged by the Liverpool Society had come from a considerable distance. He was energetic and able. He did the work well and gave satisfaction to the patients, but I am told he was not long in the town before he began to organise a rival club of his own and that he employed a young woman to canvass for him who went about collecting 1½*d.* per week from the persons whom she persuaded to join the medical man's own private club in preference to the Liverpool Society. In her active canvass this young woman did not fail to create some irritation among the better class patients who resented her importunities. Thus this medical man while working well for his employers of the Liverpool Society was also competing against them. The other practitioners in the town rose in indignation against him. They took advantage of his connexion with a purely speculative and commercial company and made this the basis of their attack. Meeting together they agreed to draw up a letter in which they qualified the newcomer's connexion with the Liverpool Society as unprofessional and declared that they would not meet him in consultation, &c., so long as he held this appointment. This action of the members of the medical profession caused considerable agitation in the town.

After a while and as his position became more and more unpleasant the medical officer of the Liverpool Society resigned his appointment. In the meanwhile the medical men practising at Weston-super-Mare had, as already described,[2] formed themselves into a union. They now approached the canvasser who had been working for the Liverpool Society. They pointed out to him that after all that had occurred it would be *extremely difficult for this company* to get another medical officer. If therefore he would consent to leave them the medical men of the town would start a medical provident organisation of their own and employ him at a fixed salary as their collector. He would not have to do any canvassing or touting, which is always unpleasant work and which was contrary to the principles of the Medical Union, but would only have to collect subscriptions due. This offer was accepted, and the Liverpool and Victoria Legal Friendly Society, having thus lost both their medical officer and their canvasser, was fairly beaten out of the field and since that day has disappeared from Weston-super-Mare. This is a signal victory and triumphantly *demonstrates* what can be done by a united effort. At the same time the employment of the young woman to canvass for the private club of the Liverpool Society's former medical officer was also given up, but the private club still exists and the Medical Union is somewhat puzzled as to how to deal with it and its medical officer. This, indeed, is the only element of discord that still exists among the medical men of the town.

The Provident Medical Association which thus arose out of the ashes of the Liverpool Society is based on the following principles. First, all medical practitioners in the town are eligible as members of the medical staff and thus the danger of creating a monopoly is effectively guarded against. All officers of the association, such as chairman, secretary, treasurer, and committee of management, &c., are elected annually. All members of the medical staff are on the committee of management and there is for working details a business sub-committee consisting of the secretary, the treasurer, and not less than three other members of the committee of management. These latter are appointed quarterly. This sub-committee meets at least once a month and more frequently when necessary. The committee of management meets once a quarter but may be convoked more frequently at the written request of three members of the staff. All notices convoking meetings of committees must state the nature of the business to be discussed. The election of members of the staff is by ballot; a two-thirds vote is necessary and the candidate must be proposed and seconded by members of the staff. Members of the profession who start practice at Weston-super-Mare without introduction cannot be elected to the association during the first year of their residence in the town, but if a member of the association or his representatives transfer his practice his successor is immediately eligible if he conforms to the rules. Of course, no medical practitioner who has been guilty of infamous conduct or other objectionable practice in a professional sense can be elected. The following important rules are worth quoting textually:—

---

[1] A reprint of the previous articles on the above subject has been published in book form entitled "The Battle of the Clubs," and can be obtained from THE LANCET Offices, price 1*s.*

[2] THE LANCET, March 4th, 1899.

> The members of the medical staff bind themselves not to undersell any of the present medical officers of existing or future clubs and not to countenance any medical practitioner who does so.
>
> No medical practitioner shall be eligible for election to the medical staff of the Provident Medical Association who subsequently to the foundation of the original staff shall have had any connexion whatever with medical aid or similar societies unless he can satisfactorily explain his position to the committee at the next quarterly meeting.
>
> No member of the association shall meet in consultation any medical man who subsequently to the formation of the Provident Medical Association practises in the town as medical officer to any medical aid or similar society.
>
> No member of the medical staff shall hold a private club. This rule is not intended to apply to what are usually understood as individual contract patients.
>
> An additional object of the association shall be to safeguard the interests of the medical practitioner, to promote fair and honourable practice, to prevent abuses in the medical profession, and finally to encourage friendly relations between medical men in the district.

This last rule it will be seen embraces all the elements for the formation of a fighting union destined to defend the economical interests of the profession. Should any serious cause of complaint arise against a member of the medical staff a special meeting of the committee is to be convoked and the person concerned is to be informed by registered letter of the details of the charge. Such charges must be brought forward by at least three members and if proved to the satisfaction of at least three-fourths of the members of the committee of management the offending party can be expelled from the association. All members of the association have to subscribe £2 towards the working expenses and to give a guarantee of £3 more if needed. The money is deposited in a bank, but all current expenses are paid during each quarter. Accounts are presented at each quarterly meeting. If there is a balance in hand £2 per member of the medical staff is to be kept in the bank as a reserve fund, after, of course, due provision has been made for all known liabilities. When this has been done, if there is still a surplus in hand it is divided among the medical staff so that each member receives a part of such surplus that is in proportion with the sum which the members on his list have subscribed to the association. The great point is that an effort has been made to insist, so far as practicable, on the principle that all members, whether they be men, women, or children, should pay a penny per week. This rule is based on the undoubted fact that women and children require more attendance and medicine than men. There is, as a rule, no entrance fee. A charge of 2d., however, is made for the subscription card unless the member is over 60 years of age and then an entrance fee of 2s. 6d. is levied. Persons who are not members and only seek to become members when they are ill are immediately admitted on payment of 10s. 6d. This subscription should be paid before the first visit of the medical officer. If not the collector must call within 24 hours and if it is not paid within another 24 hours the patient is not accepted as a member of the association. Persons suffering from chronic complaints are charged an extra weekly premium which is fixed by the committee according to the nature of the case. The premiums may be paid weekly, monthly, or quarterly in advance, but anyone who is more than six weeks in arrears will not be entitled to benefit. Members who are unable to attend at the medical officer's house must, if possible, send before 9.30 A.M., and emergency visits between 9 P.M. and 9 A.M. are charged 6d. extra. Nor does membership wholly cover the cost of surgical operations or of surgical appliances. Administration of anæsthetics and consultation with any other medical man are also charged extra. Special arrangements must be made with the medical officer for confinements, miscarriages, and vaccinations; nor does membership cover illness brought about through vice, intemperance, or immorality. The consultation fees are the property of the consultant and must be paid directly to him, but if this cannot be done the collector may collect them by such instalments as may be fixed by the consultant. Extra fees paid for confinements, miscarriages, accidents, and surgical operations are the exclusive property of the member of the staff attending the patient. In such cases the cost of medicines, surgical apparatus, &c., shall not be defrayed out of the funds of the association.

The question of medicines had next to be decided. The Provident Medical Association could not open a dispensary of its own for want of funds. This can only be attempted when there are a great number of members and a large income. Each member of the staff might have been left to dispense his own medicine, but this does not suit medical men who only give prescriptions. Consequently contracts were entered into with dispensing chemists of the town. All qualified chemists and druggists were admitted subject to the approval of the committee. A pharmacopœia was drawn up by the committee and approved by the druggist, the latter undertaking to provide only drugs of the best quality. The patients have to supply their own bottles and jars. Eight dispensing druggists accepted these terms, the members are free to select any whom they prefer, and the treasurer pays 1s. per annum to the druggist for every member on his list. The payments are effected quarterly, 3d. per quarter per member. 16 practitioners are now on the medical staff and the members may select from this list the medical attendant whom they prefer unless the member of the staff has as many subscribers on his list as he can conveniently attend and this is already the case with five out of the 16.

Such are the principal rules of the Provident Medical Association so far as its administration is concerned. With regard to the prevention of abuse the main points are the establishment of a wage limit, the refusal to accept children as members at ½d. per week, and the prevention of monopoly by accepting on the medical staff all resident and qualified practitioners. Of course, in fixing a wage limit great difficulties have arisen. Account had to be taken of the fact that at Weston-super-Mare there are hardly any workmen's houses. Cottages at 4s. or 4s. 6d. per week are not available. The rent of nearly all the poorest cottages is from 7s. to 9s. a week. Thus even workmen have to pay from £15 to £25 a year for rent and the taxes largely increase this sum. Under these circumstances the wage limit for a family is fixed at 35s. per week; but outside the town boundaries at Uphill, where rents are much cheaper, the wage limit is 25 per cent. lower. To enforce the wage limit it was at first decided that the honorary secretary should make special inquiries with regard to the income of each applicant. In a short time, however, such an undertaking was found to be far too burdensome. It was then agreed that each member of the medical staff should make investigations with regard to such subscribers as were on his own list. As a rule, of course, the members select for their medical attendant a practitioner with whom they are already acquainted; thus the medical officer knows something of most of the persons on his list even before he begins to make inquiries and it is for him to safeguard his own interests by preventing abuse. But in this there is always the great difficulty that in such a place as Weston-super-Mare nearly everyone lets lodgings. Even in the poorest back streets very high prices are paid for lodgings during the months of July and August. If rooms are let for only three or four weeks in the year this makes a considerable difference. In a poor back street as much as 30s. per week can be obtained for two small bedrooms and one sitting-room during the two favoured months of the year. Nevertheless, the letting of lodgings is such an uncertain and hazardous matter that it is not practicable to include the income which may result in fixing a wage limit.

The Provident Medical Association has now been in existence two years and there are at present 456 members or subscribers on its books. This is but a small number; on the other hand, the medical staff is not so anxious to have a large number of subscribers as it is anxious to prevent abuse. Also the number of members is increasing in a marked manner. Thus, comparing the last quarter of the second year with the first quarter of the same year it will be found that the increase of members is equal to 28 per cent. Nevertheless, the fact that there are so few members is a very serious matter, for how can the general expenses be met with so small an income? It is true that these expenses are at present very slight. The collector is paid only 7*s.* 6*d.* per week; all the rest of the work is done gratuitously and the cost of postage amounted to only 2*s.* during a whole quarter. In spite of this the medical staff have not received more than from 54 to 55 per cent. of the money paid by the subscribers. This is less than half-a-crown per annum per member on their list, and 3*s.* per annum per member can easily be obtained from an insurance company or from a benefit society. The loss that this difference represents will be willingly endured for the sake of the cause for at least a few years, but it would not be wise or fair to expect the whole of the profession to make such a sacrifice for an indefinite period. Energetic measures must therefore be taken to place the Provident Medical Association on a sounder financial basis. Of the 4*s.* 4*d.* paid by the members 1*s.* goes to the druggist, and of the remaining 3*s.* 4*d.* the collector's salary, printing, postage, and other expenses reduce the balance to less than 2*s.* 6*d.*

There is, fortunately, an obvious solution to this difficulty. By bringing to bear the necessary pressure by the united action of the entire medical profession of Weston-super-Mare it should not be difficult for the Provident Medical Association to take over the provident dispensary connected with the hospital. This latter institution is in an anomalous position and constitutes in itself a crying abuse. Indeed, it is difficult to see in what this dispensary differs from the clubs, the benefit societies, or the insurance companies which have been so warmly denounced on all sides. As already stated, the income derived from subscribers amounted last year to £356 and out of this only £87 6*s.* 9*d.* was paid to the medical officer and £5 5*s.* to a locum-tenent. Together they did all the medical work. For this total of £92 11*s.* 9*d.* no less than 6334 visits were paid to patients in their own homes, not to mention the far larger number of patients who received advice at the dispensary. Thus, if no allowance at all is made for the large number of patients seen at the dispensary, the above sum is only equal to a little over 3¼*d.* for each visit made at the patients' houses. As a rule the patients who go to a dispensary are two or three times as numerous as those who have to be seen in their own houses. On this basis the dispensary medical officer would scarcely receive more than 1*d.* per consultation whenever given. Considering that the hospital makes a profit of about £100 out of all this badly paid work the hospital dispensary may well be qualified as a "sweating" institution. As previously stated, the payment made over last year by the dispensary to the hospital amounted to £179. Even if we allow £79 for drugs and as rent for the use of premises at the hospital there remains £100 net profit, and it is difficult to see on what grounds the hospital can be entitled to this profit sweated out of the labour of the dispensary medical officer. The subscribers who pay the money have no voice in the disposal of the profits which result from their payments. If they had the spirit of organisation they could leave the hospital, hire premises elsewhere, and keep their profits for themselves.

The grievance, however, does not consist merely of sweating a profit out of an underpaid medical officer, the hospital dispensary competes disastrously against the Provident Medical Association and injures the interests of the profession throughout the town. It accepts children at ½*d.* per week and does not impose a wage limit. It is true that of late a few well-to-do persons have been struck off the books, but this is a mere dabbling with the grievance. Last year there were no less than 2279 subscribers to the hospital dispensary, of whom 1210 were children. The admissions of new members were 488 in 1898, as opposed to 399 in 1897, so that the evil is not decreasing. To the suggestion that the hospital dispensary should be abolished two principal objections are raised—firstly, that the hospital is short of funds and could not afford to lose the £100 or so profit that it makes out of the dispensary. On the other hand, the existence of this dispensary occasions a good deal of resentment against the hospital among the members of the profession. This feeling could be easily removed and in exchange the medical profession could undertake to use their influence so as to increase the subscriptions and donations made to the hospital. Such increase would more than compensate the loss of the profits derived from the dispensary. The second objection is that if the hospital was abandoned there would be some 2300 persons available for some insurance company to canvass. But in answer to this it is urged that as such an insurance company was broken up when the medical practitioners of the town were not so united and well organised as they are at present a second victory would therefore be more easy to win than the first. Of course, to this it may be urged that the first victory was due as much to good luck as to the strength of the medical organisation. But certainly the moment the hospital consents to give up its provident dispensary the Provident Medical Association should be organised and ready to take over the subscribers who belonged to the hospital provident dispensary. No interval should be allowed during which some outside insurance company could step in. Thus it will be seen that the obstacles are not very great. The medical staff of the hospital are all members of the medical union and it would be impossible for the hospital to refuse a demand made by all the medical men of the town. Nor is there any reason why the committee of management of the hospital should refuse since it would lose nothing and would, on the contrary, get rid of the discredit of running a sweating institution.

The Medical Provident Association has not got 500 subscribers, but by abolishing the hospital dispensary it may increase its membership to more than 2000 and thus acquire a sound financial basis which it does not at present possess.

Weston-super-Mare, March 5th.

THE BRADFORD AND WEST RIDING MEDICAL UNION.

This union appointed a committee to draft a set of by-laws, rules, a tariff, and the like. The draft report was submitted to a meeting of the union held on March 2nd and approved of. Besides the ordinary rules for the conduct of a society there are resolutions forming a code of medical etiquette which are sensible without being faddy. In Part VI., suggestions for a scale of fees, we find the following: "It is a responsibility ...... to endeavour to secure and maintain a fair and generous standard of fees. ...... This cannot be effected merely by raising the minimum charges of practitioners. ...... The general standard is ruled by the average fees charged by the leaders of the profession in any locality." Then follows a standard *table of minimum fees calculated* on the usual basis of rental. We are glad to see that the minimum club tariff is at the rate of 4*s.* per member per annum.

MEDICAL ATTENDANCE IN THE DURHAM COALFIELD.

We have upon previous occasions[1] commented on the relations between miners and their medical men not only in the Durham coalfield but also in the Welsh coalfield. The matter in the Durham district has reached a rather acute stage, for we see from various paragraphs in the *Newcastle Daily Chronicle* that many miners' associations have decided to refuse the demand of the medical men for a rise of 50 per cent. in the subscriptions. An editorial article from the same journal points out with great force that the miners are in an "awkward predicament."

> They cannot dispense with medical attendance. They cannot import cheap medical labour from outside, because to do that would be to descend to measures which the basest and most brutal capitalist does not now dare resort to; nor can they employ any person who is not a member of the medical union, because that would be to encourage the blackleg. The blackleg, we know, is so odious to trade unionists that no self-respecting unionist pitman will descend the mine with him or even pray in the same chapel with him. The only way out of the deadlock that we can see is for the miners to pay the extra 50 per cent. and thank God that trade union principles are extending.

This is common-sense. It may be very fine argument to say that the consciousness of duty done will repay a medical man for all his toil, but this feeling, though praiseworthy, will not feed or keep the practitioner, and not even the most grasping income-tax commissioner would assess such consciousness under schedule D.

The matter is being fully discussed in the local newspapers and in the *Newcastle Daily Leader* of March 7th is a very temperate letter from, we presume, a miner. This gentleman whose name is James Henderson advises his fellow miners to meet the medical men in a friendly spirit and to try to arrange matters amicably. This is very sound advice. The miner is as a rule a hard-headed and sensible man and so is the medical practitioner, although there are exceptions on both sides. In another letter attention is drawn to the practice which seems to prevail of a practitioner or firm of practitioners keeping numerous assistants simply to do the colliery work.

---

[1] THE LANCET, Nov. 12th and Dec. 24th, 1898, and Feb. 4th, 1899.

Medical Attendance in the Welsh Coalfield.

In our issue of Dec. 24th, 1898, we mentioned the formation of the Eastern Valley Medical Association and its demand that the terms upon which medical assistance was guaranteed should be raised. Most of the works and collieries in the district have already granted an increase of *1d.* in the £, but Cwmbran Colliery has refused this rise. Therefore the medical man in charge, Mr. O. S. Bowker, has resigned. The following resolutions were passed at a meeting of the association held on March 4th:—

1. Proposed by Mr. R. W. Haslett and seconded by Mr. S. B. Mason that the secretary write to various medical societies requesting them that in the event of an advertisement appearing for the position of surgeon to any colliery or works in the Eastern Valley, and especially the Cwmbran Colliery, they will use their influence to dissuade intending applicants for the appointment.
2. That intending applicants for the vacant post be requested to communicate with the honorary secretary of the Eastern Valley Medical Association, Mr. A. B. Avarne, Crossfield House, Blaenavon, Mon.

⁂ We have up to the present treated the question of the pay of colliery surgeons in another column. As the question has now assumed a phase of strife between the medical unions and the miners' unions we have transferred it to the present heading.—ED. L.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Further Experiments with Curative Serum.—The Plague Commission.—The Improvement Trust and the Housing of the Poor.—The Progress of the Plague.—The Indian Subordinate Medical Service.—Opposition to Inoculation at Hyderabad.

THE latest experiments with regard to plague curative serum do not throw out much hope of success. Two kinds are now being tried in Bombay. About 25 cases have been inoculated with Roux's serum received from Paris and a similar number of cases have been taken as controls. The results so far do not show any advantages among the injected cases. The mortality in both series has been high. About 30 cases have been inoculated with Lustig's serum which has been prepared by Dr. Galeotti at the laboratory in Bombay. The results here, also, are equally doubtful. Little or no improvement is shown in the mortality, but to those who survive some benefit is thought to accrue in the lessened tendency to suppuration in the glands. No comparison can be made with the average of cases admitted to hospital because moribund cases are for the most part excluded in these experiments. One is loth to report that no appreciable benefit can be detected in this form of treatment of plague.

The Plague Commission has been taking evidence at Baroda. Mr. A. D. Cooper, the health officer, stated that plague in a mild or modified form was present along the Konkan Coast at Revadanda and other places in North Konkan for some years before its presence was officially recognised in Bombay. Cases of painless general lymphatic enlargements with and without fever were also observed in Bombay but as the significance of the phenomenon was not recognised no notes have been kept by the observers. In Calcutta, he said, cases of this description had also given rise to great difference of opinion. Plague appeared in Baroda in the latter part of 1896 brought by a patient to Kharvawad from Surat. He had found that nearly two-thirds of the total deaths from plague escaped detection which shows the great difficulty of working in the midst of an ignorant, obstructive, and secretive populace and also marks the necessary limitations of a body of men working in the midst of a large unwieldy population. He also referred to the occurrence of cases of plague in houses which had been thoroughly disinfected by perchloride of mercury. He held that quarantine and watching and restricting the movements of the people should be done away with as being inadequate for the purpose of protection and therefore unjustifiable. With regard to the deaths of monkeys he had made the observation that these sagacious creatures left off frequenting the neighbourhood where they found plague. As regards the bottles of prophylactic serum he noticed a copious granular sediment almost invariably. On removal of the cork a foul putrescent smell was discernible—a smell very much like that of putrefying meat—but no living organisms were detected microscopically, not even sarcinæ. The sediment showed some inorganic crystals and some irregular forms of matter which imbibed the stain of aniline blue. Other evidence reported is of no interest.

The district of Bombay which is to be razed to the ground under the Improvement Trust Scheme had a death-rate in 1896 of 40·42, in 1897 of 59·10, and in 1898 of 61·61. Concerning the displacement of the population on which much apprehension prevailed the chairman has announced that the board would build accommodation for the poorer and working classes occupying premises actually on the line of the proposed streets or sanitarily unfit for habitation and that such accommodation will be provided where possible *in situ* or in the vicinity, but encouragement will be given to the population to spread by also building in the northern suburbs.

The plague shows no sign of abatement. There has been a further development in Bombay city and a rise in the Belgaum and Bijapur districts. At Karachi it shows signs of spreading slowly and steadily, cases having occurred in as many as seven quarters of the town. An increase is reported in the Madras Presidency also at Anantapur and North Arcot. Also in Mysore city five plague deaths have occurred at Jullunder in the Punjab and two suspected cases have been discovered in Calcutta. In the Kolar Gold Fields it is rapidly increasing. For the past week 2228 deaths have occurred in the Bombay Presidency, of which number 543 are recorded for Bombay city. 1000 would more nearly be the correct number. An examination of the excess of deaths over the average of the three years preceding the plague outbreak shows that in Bombay city probably over 60,000 persons have died from plague. The official figures, however, are much lower.

The Indian Subordinate Medical Department is admittedly undermanned, the members bear great responsibilities and the work is onerous, but the Government of India has sanctioned a scheme of changes in the conditions of service of the members of its Military Assistant Surgeon Branch. Excluding the commissioned ranks, military assistant surgeons are divided at present into the following classes: Third class, Rs. 50 per mensem; second class, under five years' service, Rs. 85 per mensem; second class, above five years' service, Rs. 100 per mensem; first class, under five years' service, Rs. 150 per mensem; first class, above five years' service, Rs. 200 per mensem. The service will henceforth be divided into four classes on the following rates of pay, the existing class on Rs. 50 being abolished: Fourth class, Rs. 85 per mensem; third class, Rs. 110 per mensem; second class, Rs. 150 per mensem; first class, Rs. 200 per mensem. In lieu of the present system of promotions to fill vacancies in each class a service of five years in the fourth class and of seven years in the third and second classes respectively will entitle an assistant surgeon to promotion to the next higher class. He will thus ordinarily reach the first class on Rs. 200 after a total service of 19 years, instead of 24 years, the present average. These new regulations will have effect from the commencement of the next financial year. This department is largely recruited from the Eurasian sons of European warrant and non-commissioned officers, and it offers a very fair career for them. The *personnel* of the department being scanty the work is laborious. It is said that in every military hospital two men are doing the work of three. Very little leave also is obtainable. On the whole, however, the service is a satisfactory one.

Plague shows no signs of abatement in Hyderabad territory, but fortunately its ravages are exclusively confined to remote villages. It is said that very strict measures are being adopted with the hope of preventing its incursion into Hyderabad city. Official opposition to inoculation is still very pronounced. In consequence [illegible] of [illegible]les of the prophylactic which were [illegible] been found to have gone ba[illegible] there have thought fit [illegible] cop[illegible] and to describe Haffkine's fluid as "a putrescent organic liquid." They appear to shut their eyes to the results obtained elsewhere, but deign to withhold their opposition to the use of it after it has been sterilised in the laboratory of the Hyderabad Medical School. The preparation, storage, and distribution of this material doubtless require very great care and it is known that occasionally a bottle of it has been found to have undergone change. The fault, however, does not necessarily lie with the distributing laboratory in Bombay and it is quite possible that scientific precautions may not have been exercised in its use. To tamper with it in the Medical School at Hyderabad is wholly unjustifiable. Specimens as to which any doubt exists should be discarded. Studious precautions are practised in the laboratory at Bombay and the fluid is sent out fit for employment. There have been very few untoward results following its use. With some operators abscesses are not uncommon but there is every reason to believe that they are avoidable. At any rate, the fault does not necessarily lie with the serum. With regard to the prophylactic serum your readers will find further particulars in THE LANCET.[1]

Feb. 11th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Measles and the School Board.

AT the meeting of the Manchester School Board a fortnight since great dissatisfaction was expressed at the action of the Sanitary Committee of the corporation with regard to measles. A report was presented by the Office Committee as to the closing of the schools by order of the Sanitary Committee of the City Council on account of the prevalence of measles and the serious effect such action was having on the school attendance. During 1897 no less than 39 schools, of which 24 were voluntary schools, were closed. In Manchester the rule at present is for the medical officer to close a school when the actual cases of measles exceed 10 per cent. of the average attendance, and this, the report urged, was going beyond the recommendation of the Local Government Board. It was contended also that schools were being closed as a matter of routine and unsuccessfully as regards preventing the propagation of disease. It was stated that in Birmingham, Bristol, Huddersfield, Hull, Liverpool, Salford, and Sheffield schools were not closed on account of the prevalence of measles and nowhere did the practice obtain to anything like the extent which it did in Manchester. The disease has been very prevalent here of late years and "the attempt to cope with the disease by the frequent closing of schools had not succeeded." A circular issued by the medical officer of health, dated Feb. 16th, recommending the exclusion from school "of every child showing symptoms of a cold" would, if acted on, the report held, in inclement weather nearly empty the schools. The report said that "in the opinion of the committee the solution of the problem of how to prevent the spread of epidemic sickness in schools lay in the rigid exclusion of individual cases." The prevention of the spread of measles will certainly require the harmonious working and the best efforts both of the board and the medical officer. The chairman of the board deplored any conflict with the sanitary authority but "maintained that it was the duty of the board to ascertain from the Education Department and the Local Government Board" the right course to take.

Generous Offer to the Manchester Hospital for Consumption.

At the annual meeting of the Manchester Hospital for Consumption and Diseases of the Chest and Throat, held in the town-hall on Feb. 22nd, the medical board reported that in the out-patient department there were 33,684 attendances, the number of new patients being 10,914. The 50 beds at the Bowdon Hospital for in-patients were constantly occupied and "before many months passed it was anticipated that the Liegehallen system of open-air treatment would be in full working order." The Lord Mayor, in moving the adoption of the report, said that they were doing their best in Manchester to prevent the sale of milk from tuberculous cows and had inserted clauses in the Corporation Bill for that purpose, and as Lord Mayor he should make it his duty to see how far they could carry the clauses in question. Dr. A. Ransome, now of Bournemouth but formerly one of the staff of the hospital, gave an address on the Prospect of Abolishing Tuberculosis, in the course of which he said that the disease was to be abolished "by stopping the presence of the seed by taking care that no susceptible persons should be found in the community, and, above all, by rooting out what he had ventured to call tubercle nests in all great towns and especially, he was sorry to say, in Manchester. Practically, then, they would have to renovate the town." He wished the admirable by-laws of Liverpool and London dealing with obstructions of light could be adopted for Manchester. The gradual renovation of the town can be brought about if the requisite money can be found, but the getting rid of the susceptibility to tuberculosis is a more difficult matter, for the human factor comes in with its varying degrees of ignorance, stupidity, and helplessness. Mr. W. I. Crossley, chairman of the board, in moving a vote of thanks to the Lord Mayor and the Lady Mayoress said that they had 50 beds at Bowdon but there was no room for more, "therefore it was proposed that 100 beds should be put up elsewhere and money was offered for that purpose if Manchester would guarantee to support the beds." It is an open secret that the chairman himself makes this munificent offer to build a hospital of 100 beds if Manchester will maintain it, and surely the citizens who can easily raise the £3000 or £4000 a year required will not fail to provide what will be paid back in the increased health and well-being of the community.

A Tragedy Averted.

It rarely happens that anything humorous lights up the gloom of attempted suicide; but yesterday at the Manchester police-court a man was brought up who after a quarrel with his wife sent a son for sixpennyworth of carbolic acid which was refused to him. He was then sent for sixpennyworth of chlorodyne but with the same result. The prisoner then went himself to the druggist's shop and asked for sixpennyworth of chlorodyne but received instead a bottle containing a halfpennyworth of carbolic acid with a liberal quantity of water. The man went home, took the dose, and kissed two sons, saying that he was leaving them as he had taken poison. Then he kissed his wife who was brought in from a neighbour's house and bade her good-bye. He refused to take an emetic and the policeman who was called in thought he was "rather lively" for one who had taken poison. When asked he said that he had taken "sixpennyworth of chloride of lime." The prisoner had taken a little drink as well as a little poison. The druggist whose suspicions had been roused by a young boy coming for carbolic acid and then for chlorodyne was complimented by the bench on his shrewdness and the prisoner was remanded for some days to give him time for reflection.

March 7th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

St. Andrews University.

MR. T. G. NASMYTH, M.D. Edin., D.Sc., D.P.H., medical officer of health of Fifeshire, has been appointed examiner in Public Health for St. Andrews University.

The Will of the late Professor Rutherford.

Professor Rutherford in his will bequeaths to the Medical Faculty of the Senatus of the Edinburgh University his portrait on porcelain by Barraud and Jerrard; to the Senatus Academicus all the diagrams used by him in the physiological department, to remain in that department in charge of the Professor of Physiology, and also all his books and journals relating to physiology, histology, anatomy, chemistry, physics, natural philosophy, and pathology, on condition that they are to be placed in the physiological department in charge of the Professor of Physiology or Institutes of Medicine to assist him in the work of teaching and examination.

Edinburgh Royal Infirmary.

At the weekly meeting of the managers of the Edinburgh

---

[1] THE LANCET, Feb. 27th, 1897, p. 604; March 13th, 1897, p. 767; March 27th, 1897, p. 907; April 3rd, 1897, pp. 976, 981; July 24th, 1897, p. 225; August 7th, 1897, p. 333; and Dec. 11th, 1897, p. 1546.

Royal Infirmary, held on March 6th, Mr. James Dunsmure, F.R.C.S. Edin., took his seat as a representative from the Royal College of Surgeons on the Board of Management, in room of the late Sir John Struthers.

The Chair of Physiology in Edinburgh University.

The curators in whom the patronage of the chair of Physiology in Edinburgh University is vested are inviting applications for the chair which has been rendered vacant by the death of Professor Rutherford. Candidates are requested to lodge their applications and eight copies of their testimonials with the clerk to the curators, Mr. R. Herbert Johnston, W.S., 66, Frederick-street, Edinburgh, not later than Saturday, May 20th next. One copy of the application should be signed. The election will be made on a date to be afterwards fixed.

The late Dr. John Stuart Smith.

The death is announced on March 1st at his residence in Edinburgh of Dr. John Stuart Smith, retired Surgeon-Major, Army Medical Department, at the age of 84 years. Dr. Smith was an elder brother of Lord Strathcona and Mount Royal. He retired from active service about 35 years ago. He was educated at Aberdeen University, where he graduated in arts, and in the University of Edinburgh where he obtained his degree in medicine. He then entered the Army Medical Department and served twice in India and in the first Chinese War, being present at the taking of Canton. He served in Ireland during the time of the typhus fever epidemics in 1847 and 1848. He also had principal medical charge in New Zealand during the Maori War.

Church of Scotland Deaconesses' Hospital.

The fourth annual meeting of the contributors and friends of the Church of Scotland Deaconesses' Hospital was held in Edinburgh on March 1st. The report stated that the accommodation consisted of 24 beds in all. The number of patients treated during the year was 333, as against 264 in 1897. The average daily number under treatment was 23. In all 179 operations had been performed by the surgeon-ordinary, the extra physician for diseases of women, and the extra surgeons for diseases of the ear and throat and eye, and no deaths had resulted. The accounts showed a balance in hand of £207 5*s*. 7*d*.

Edinburgh University Honorary Degrees.

At a meeting of the Senatus Academicus on March 4th the Senatus resolved to confer the honorary degree of Doctor of Laws on the Right Hon. Lord Balfour of Burleigh, Secretary for Scotland, Lord Rector of the University of Edinburgh, on March 14th, the occasion of the Lord Rector's address, and at the graduation ceremonial on April 14th on several other eminent persons, among them Mr. William Mitchell Banks, M.D. Edin., F.R.C.S. Eng.

Academic Honours to Medical Men.

Among those who are to receive the honorary degree of LL.D. from the University of Aberdeen are Mr. James Frederick Goodhart, M.D., F.R.C.P. Lond., and Mr. Charles Stewart, M.R.C.S. Eng., F.R.S., Conservator of the Museum of the Royal College of Surgeons of England.

March 8th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Poor-law Medical Service.

A SERIES of rules under the new Local Government Act affecting the Irish dispensary medical service was published in the *Dublin Gazette* of March 3rd. Important innovations are made in the system of granting medical relief tickets and the payment of salaries during incapacity from illness is placed on a satisfactory footing. Only guardians, relieving officers, and wardens appointed by the guardians will be empowered to issue relief tickets and they may not delegate that power to others nor may they sign tickets in blank and leave them to be filled up by others. Provision is made for establishing a reduced scale of medical fees for poor persons unable to pay the usual fees. During the illness of a medical officer the guardians must pay to his substitute such remuneration for his services as the Local Government Board may approve or direct. Continuous sick leave on full salary may be granted to a medical officer for six months, after which he may be allowed salary for a further period of six months at not more than half the ordinary rate.

Health of Belfast.

At the meeting of the city council held on March 1st it was reported that in the past four weeks 229 cases of zymotic disease had been notified, 56 of scarlet fever, 54 of typhoid fever, 41 each of simple continued fever and erysipelas, 25 of diphtheria, six of membranous croup, five of puerperal fever, and one of typhus fever. There were 65 deaths from zymotic disease, 93 from phthisis, and 167 from respiratory diseases. The annual death-rate was 25·1 per 1000. The outbreak of typhoid fever has died out and the disease has again assumed the normal level which seems to be persistent in Belfast. 54 cases have been notified in the month, against 222 in the corresponding month of last year, and the deaths were 10, as compared with 27 last month. Measles, scarlet fever, and influenza are also very prevalent.

"The University Education Question in Ireland."

Professor Whitla, Professor of Materia Medica in Queen's College, Belfast, has published through Messrs. Strain and Sons at the modest price of 6*d*. a very clear little pamphlet with this title. All who want to understand the "ins" and "outs" of a very difficult matter should read what Professor Whitla has to say.

The Ulster Medical Society.

The March meeting of the Ulster Medical Society was held on the 2nd inst. in the anatomical department of Queen's College, Belfast. In the large room of the anatomical school a typical collection of fractures from the medical museum was placed, as well as specimens illustrating surgical pathology and deformities and medical pathology. The most valuable demonstration of the evening was that given by Professor Symington and his assistant, Dr. Johnstone, on "The Topographical Anatomy of the Thoracic and Abdominal Viscera." Two cadavers (male and female) have since November been carefully prepared and hardened in formol and so deftly manipulated that the various organs can one by one be removed and replaced again so that a most extraordinary and vivid idea can be given of the whole body or of any separate region of the chest or abdomen. Finally, Dr. Johnstone read a paper on Two Fœtal Monsters and Professor Symington illustrated by diagrams a Comparison of the Pelvic Viscera and the Pelvic Floor in Two Adult Male Subjects.

Death of Mr. P. J. O'Hara, M.D. R.U.I., Ballymena.

I regret to announce the death of Dr. O'Hara which took place on Feb. 28th at the residence of his father at Ballylesson, Ballymena. Dr. O'Hara, after studying at Queen's College, Cork, and in Dublin, graduated M.D. of the Royal University of Ireland in 1884 and shortly afterwards settled down in his native district, Ballymena, where he gained a large and lucrative practice. He was a skilful physician and a great favourite and his death is much deplored in Ballymena.

The Royal Victoria Hospital, Belfast.

For some time past Mr. Henman (of Birmingham), the architect, and the staff of the Royal Hospital have been holding consultations in reference to the plans of the new Royal Victoria Hospital and, although matters are not finally settled, the principles of its construction are in the main agreed upon. It is to be heated and ventilated on the "plenum" system and the wards are to be one storey in height.

The Water-supply of Cork.

The water-supply of Cork has been seriously impeached, apparently on good grounds, by Mr. H. W. Hunter in a letter to the *Cork Constitution*. That journal in a leading article calls upon the corporation of the city to hold a searching inquiry into the matter.

March 8th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Hospital Abuse in Paris.

AT a meeting of the [illegible] ...ntly held Dr. Le Blond proposed [illegible] submitted to the Superior [illegible] —

1. The hospital shall [illegible]
2. Hospital treatment [illegible]

domestic servants, workmen, and employés whose wages do not exceed a certain sum to be hereafter determined. 3. No one whose rent exceeds in Paris 1000 francs or who pays rates shall be entitled to benefit by the services of a hospital. Exceptions may be made in the case of those who after a searching inquiry are found to be incapable of paying for a serious operation at the usual fees. 4. In every district shall be nominated one or two charitable persons whose duty it shall be to make inquiry into every case before such case be admitted to the hospital and to whom every patient desirous of entering a hospital must apply. 5. The medical men attached to the charitable organisations of every quarter shall have the right to give out admission tickets to hospitals if in their opinion the patient is really poor and unable to be properly cared for at home. Such an admission ticket shall be followed up by an inquiry into the merits of the case. 6. No sick person shall be admitted at once into a hospital without inquiry except in the case of an emergency.

Prognosis in Erysipelas by Examination of the Blood.

Speaking at the meeting of the Society of Biology held on Feb. 18th M. Chantemesse took occasion to remark that there existed hardly any clinical signs by which could be diagnosed the course of an attack of erysipelas, whether it would resolve or whether, if once resolved, a relapse would follow. Examination of the blood in erysipelas, whether made during an attack or during the period of convalescence, furnished valuable information upon this matter. *The curve of the number of leucocytes* in a case of erysipelas followed very closely that of the temperature, but this leucocytosis did not show equally throughout the various blood elements. There were polynucleated cells which showed an increase as soon as the malady was established, while at the same time the number of mononucleated cells diminished, such diminution occurring chiefly in the lymphocytes. When recovery took place it was signalised by a fall in the number of polynucleated cells. The eosinophile cells which fell in number during the course of the illness only appeared again when the blood infection was altogether at an end. M. Chantemesse had noticed that sundry suppurative affections which appeared in the course of erysipelas were generally of favourable import, for he had often noticed patients with erysipelas recover who had suffered from this complication. M. Malassez stated that some time ago he had occasion to examine the blood in a number of cases of erysipelas. He had always noticed profuse leucocytosis and the formation of an abscess in such patients produced a veritable shower of white corpuscles. M. Vagnez said that he had often been able to prognose septic affections by finding marked leucocytosis in patients who were under treatment.

The Water-borne Origin of Enteric Fever.

At the meeting of the Society of Biology held on Feb. 28th MM. Ch. Nicolle and G. Spilman communicated a paper upon the Importance of the rôle played by Drinking Water in the Etiology of Enteric Fever. A very considerable number of facts went to support this theory. The observers thought that one very striking example which they were able to bring forward had not yet been made public. The town of Falaise possesses an excellent supply of drinking-water of which a battalion of infantry forming the town garrison partook. Enteric fever is very rare among the men forming this garrison, there having been only four cases in 10 years—namely, two in 1889, one in 1891, and one in 1892. At the close of last year, however, there were many interruptions to the supply of water to the barracks; three times was the supply interrupted between Dec. 8th and 15th and once between Dec. 22nd and 25th. Fatigue parties were sent out to the various hydrants of the town to bring in water. Some of these fatigue parties, however, instead of going to the appointed places for their water—places which had been very carefully chosen—preferred, because it was not so far to go, to get water from two wells, the water of which, manifestly polluted by certain cesspools in the neighbourhood which had not been emptied, had not been used by the civil population for a very long time. As a consequence four cases of enteric fever appeared, the diagnosis being verified by the serum test. The first appeared on Dec. 27th, the second on Dec. 28th, and the two remaining ones on Jan. 3rd. None of the men attacked had been on leave for a long time. Two others were admitted into hospital at the same date with the same symptoms, but the diagnosis was not confirmed when the cases were submitted to the serum test. Working with these facts as a basis Dr. Loustalot, the surgeon-major, examined some samples from the wells in question in the bacteriological laboratory of the Rouen School of Medicine. Here, following the method of Elsner, he had no difficulty in isolating from the water of one well the bacillus typhosus together with another bacillus very similar to the first but differing from it in that it gave no agglutinative reaction with the serum of animals inoculated with an undoubted enteric culture. In the water of the second well only the bacterium coli was found. It was difficult to understand the part played by the bacillus which is so like the real bacillus typhosus. So close is the resemblance that but for the serum test it would certainly have been called a real bacillus typhosus. Possibly there is some relation between this microbe and the two doubtful cases of enteric fever in which the serum test gave a negative result. If it had been wished to experiment upon human beings as to the part played by water in the distribution of typhoid fever one could not have a more striking result from experiment than the condition of matters at Falaise.

March 7th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Cultivation of the Enteric Fever Bacillus.

A NEW method available in the diagnosis of enteric fever has been described by Dr. Piorkowski at a meeting of the Berlin Medical Society. In 1898 he discovered that a marked difference existed between a colony of bacterium coli and one of the enteric fever bacillus, for the former grew in gelatin with a distinct edge whilst the latter showed irregular radiations. From a practical point of view it was, however, a disadvantage that these differences were visible only *after 48 hours. Dr. Piorkowski has now succeeded in* accelerating this development by using media containing only a very small amount of gelatin. The culture medium used by him is composed as follows: urine two days old which has become alkaline and has a specific gravity of 1020 is mixed with 0·5 per cent. of peptone and 3·3 per cent. of gelatin, boiled in a water-bath, and filtered. After being run into glass tubes it is sterilised for 15 minutes and on the following day again for 10 minutes at a temperature of 100° C. In this culture-medium the bacterium coli appears after 20 hours in round, yellow, fine-grained and sharply-defined colonies, whilst enteric fever bacilli show a peculiar arrangement in the form of tendril-like figures somewhat similar to spirochætæ and quite different from the colonies of bacterium coli. These characteristic signs, however, appear only in the above culture medium; on 10 per cent. normal gelatin no difference between the two species of bacteria was visible. In test tubes containing the above urine-gelatin the colony of bacterium coli appears in a fine grey-white line and grows largely on the surface of the gelatin; enteric fever bacilli only grow within the gelatin and not on the surface. The same differences appeared whether specimens were taken from water artificially infected with bacilli or from the fæces of patients. In one case the characteristic symptoms described by Dr. Piorkowski were present, whilst Widal's reaction was not obtained.

A Congress on Tuberculosis.

A congress to discuss measures against tuberculosis will be held at Berlin from May 24th to 27th under the patronage of the German Empress and under the honorary presidency of Prince Hohenlohe, the Imperial Chancellor. The subjects of discussion will be: (1) Spread of the Disease, to be introduced by Dr. Köhler, Director of the Imperial Health Office, and Dr. Krieger, chief of the Medical Department of Alsace-Lorraine; (2) Etiology, by Professor Koch and Professor Fränkel; (3) Prophylaxis, by Professor Gerhardt and Dr. Schjerning, of the Medical Department of the War Office; (4) Treatment, by Professor Ziemssen of Munich and Professor *von Schrötter of Vienna*; and (5) Sanatoria, by Dr. Dettweiler of Falkenstein and Dr. Gaebel, director of the Imperial Insurance Office. The Governments of the States of the German Empire, the municipal authorities of the greater towns of Germany, the medical corporations, the employers' associations, the medical faculties of the German universities, and other bodies have been invited to send representatives to the congress. The Presidents of the congress are the Duke of Ratibor and *Professor von Leyden.* The committee consists of a great many distinguished medical men and philanthropists, among whom may be mentioned Professor Koch and Professor Gerhardt of Berlin, Professor Ziemssen of Munich, Professor Flugge of Breslau, Professor Liebermeister of Tübingen, and others

A Female Doctor of Philosophy of Berlin University.

An event for ever memorable in the history of Berlin University happened on Feb 18th, when for the first time academical honours were conferred upon a lady, Fraulein Neumann, who was created Doctor of Philosophy. During the last few years the Government and the University authorities have shown themselves not unwilling to admit females to academical studies, but a good many difficulties due to the regulations at that time existing had to be overcome before the new "doctor' could attain the object of her ambition The graduation ceremonial drew an enormous audience, so that the *aula magna* of the University was overcrowded long before the commencement of the proceedings It was obviously not by interest in the "dissertation' that so many people were attracted, and the majority of the audience were hardly likely to understand much about the "disputation" in matters of philosophy, physics, and mathematics Most of those present were evidently moved by mere curiosity to see a lady taking the principal part in the quaint usages of a university graduation and were not a little astonished to hear her disputing without any embarrassment against her "opponents,' of whom two were men and one was a lady doctor of a Swiss university After the 'disputation" was finished the dean, Professor Schwarz, addressed the meeting, pointing out the exceptional interest of this occasion on which academical honours were for the first time in the history of the University granted to a candidate of the female sex He congratulated the University authorities on their attitude towards the question of female education and the candidate on her perseverance After this speech he proceeded to confer the degree in the customary manner and the new "doctor" was received by the audience with loud applause A further proof of the change which is coming over public opinion with reference to the higher education of women is furnished by the intention of the Government to admit women to the examinations for medical qualifications Some periodicals have reported that this question will be decided in connexion with the forthcoming alterations in the State examinations in medicine, notwithstanding the opposition of leading medical men An evidence of unfriendliness to medical women was recently given by the committee of the Berlin Medical Society A medical woman in Berlin, qualified in Switzerland, made an application to be received as a member but was refused by the committee presided over by Professor Virchow because the regulations of the society were considered to preclude the admission of female members Two members of the society then moved that the regulations should be altered, but the committee refused to support the motion and when it was again brought before the committee it was once more rejected, so that according to the rules of the society the question must now be postponed for a year

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Health of Leo XIII.

"VENI, vidi, vici, Professor Mazzoni is entitled to say considering the promptitude with which his august patient has responded to his surgical intervention The incidents preceding and attending this the sharpest curve yet described by the comparatively even tenour of the Pontiff s health are soon told For two years past he has suffered with progressive frequency from intestinal catarrh of a mild description, from occasional winter "raffreddori" (colds), and now and again from vertigo, but it was only quite lately that his body physician, Dr Lapponi, had to accentuate his precautions and impose a peremptory restriction on the number and duration of his receptions Among other ceremonies of this kind the audience fixed for the Princess of Sweden had to be postponed, but the rest and relaxation from official strain soon told and for about a fortnight thereafter the Pope was as accessible as ever, while the magnificent weather at the close of February tempted him out into the Vatican Gardens On Sunday, Feb 26th, however, after celebrating mass in his private chapel, he complained of slight malaise and loss of appetite, whereupon Dr Lapponi concluding that it was one of the usual "raffreddori" caught during the garden exercise, prescribed repose In the evening the pulse was regular, but the skin was dry On the next day it was deemed advisable to keep the patient in bed till on Tuesday morning, the febricula returned contemporaneously with pain in the axilla. A minute general examination thereafter disclosed some inflammation of an old cyst in the left lumbar region—a cyst of the size of a turkey's egg, hæmatic in nature and hitherto so quiescent as hardly to give notice of its presence Immediately Professor Mazzoni was called in with the Pope s sanction (quite necessary to obtain under existing relations between the Vatican and non clerical Rome) and removal of the cyst was proposed and agreed to The Pope, with a deprecatory smile, asked "E dunque necessario tagliare questa amica cistr che ho con me da tanti anni?" (Is it necessary to apply the knife to this friendly cyst which I have had about me for so many years?) and the pleasantry with the pluck which it implied helped to reassure the operator in dealing with a nonagenarian Enucleation was performed without chloroform but with such local anæsthesia as was possible and during the operation the Pontiff gave only three half audible groans, ending in "basta, basta" (enough, enough) when the encapsuled tumour was finally removed The after treatment was equally successful and the last bulletin announced full convalescence, all the symptoms being satisfactory What rendered surgical intervention necessary, and that immediately, was the incipient inflammation manifest in the cyst and the danger of its contents, so modified, finding their way into the circulation with peradventure toxic results Another consideration counselling prompt interference was the patient's 89 winters, there was not an hour to lose. His energetic will was in his favour and this—not the blunted sensibility of old age—explains the absence, nearly perfect, of all expression of pain in a very partially anæsthetised patient But that energy was more mental than physical and there is no saying how soon it also may have collapsed, had the inflammatory condition of the cyst been allowed to extend It may interest your readers to know that Professor Gaetano Mazzoni is a *privat-docent* in special pathology in the University of Rome and "chirurgo primario" in the San Giovanni Hospital He is a nephew of the great Roman surgeon Costanzo Mazzoni—a teacher and operator of European fame—of whom THE LANCET gave an extended obituary notice in 1885 '

Undergraduate Mutiny in the University of Turin

The riots at Palermo and Naples to which I referred on Jan 28th have had their counterpart in Turin, where the military arm has had to be invoked and many students have been arrested The cause of this most unseemly outbreak resolves itself into the dissatisfaction of the medical undergraduates, mostly those of the second, third, and even fourth years, at the appointment of Professor Fusari to the chair of Anatomy This gentleman, with every scientific qualification for the post including an admirable record as a teacher, was, it seems, the reverse of a *persona grata* to the students whose preferences were all for another; but the authorities kept true to their original choice which His Excellency Dr Baccelli Minister of Public Instruction, confirmed Ever since the University has been in a ferment. Professor Fusari has been boycotted; he has also been violently interrupted in his prelections and no insult or contumacious demonstration on the part of his young adversaries has been spared him Matters came to a head on Saturday, Feb 25th, when Professor Fusari was engaged with a class of first year s students who had the courage to attend The rebellious majority, many of them at a stage of their curriculum when a steadier, more dignified demeanour might have been expected, proceeded to interrupt the lecture. Foiled in their attempt to get into the room they tried to rescue their ringleader and laid violent hands on the vice inspector of the public force The captain of carabineers then fired a revolver in the air which brought up reinforcements, whereupon the rioters fled, leaving three of their number prisoners Later in the afternoon an attempt to rescue these resulted in more arrests By this time the Bersaglieri (a crack infantry regiment) came up, followed by another flight of the rioters and still further arrests—those arrested, like their predecessors, being accommod [illegible] w [illegible] lodgings" [illegible] the judiciary prisons. Those students who are still at large were, when last heard of, patrolling the streets in a heavy snowstorm, invading the newspaper offices, and generally making themselves and their "grievances" known. Dr. Baccelli is at the moment engaged in examining the circumstances of the riots with a view to inflicting disciplinary penalties on their authors. He will have the sympathy of all loving Italian learning and professional decorum if his action is "short, sharp, and decisive."

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Treatment of Typhoid Fever.

AT a recent meeting of the Wiener Medicinisches Doctoren-collegium Dr. V. Jez described the mode of preparation and the action of the "antityphoid extract" prepared by himself. Rabbits after being made highly immune by intra-peritoneal injections of bouillon-cultures of the typhoid bacillus are killed, and the thymus gland, spleen, bone-marrow, brain, and spinal cord are rubbed up together with a solution of common salt, alcohol, and glycerine, a small quantity of carbolic acid and of pepsine being added. The liquid thus obtained is put on ice for 24 hours and after filtration yields a reddish liquid which is by Dr. Jez called "antityphoid extract." It is administered internally in doses of from 20 to 30 grammes (from three-quarters of an ounce to one ounce) every two hours in cases of typhoid fever. Dr. Jez has treated 18 cases of typhoid fever with this remedy and he states that he obtained very favourable results from its use. The temperature curves lose their typical character and the fever shows remissions under the use of the extract; at the same time the pulse becomes better and apyrexia sets in very soon. Dr. Jez states that the use of this remedy is not attended with any inconvenience. If further trials of this extract should confirm these results it would be very interesting from a theoretical point of view because this extract would be the first antitoxic remedy which would act from the intestinal tract and would show in this respect a similarity with the organic extracts prepared from the thyroid or from the suprarenal glands.

Infection and Blood-pressure.

In a preliminary communication recently made to the Gesellschaft der Aerzte of Vienna Dr. Federn drew attention to the influence of the infective process on the blood-pressure, an influence which is very marked in malaria and in scarlet fever. According to his researches rise of temperature has no influence on the blood-pressure unless it is associated with the diseases mentioned. He believes that a high blood-pressure may be regarded as a diagnostic means corroborative of scarlet fever in doubtful cases, as this symptom is absent in other febrile diseases and that it has some connexion with the infection itself.

The Sale of Organo-therapeutic Remedies.

The Government has recently issued an order prohibiting the sale of organo-therapeutic preparations by druggists unless they are prescribed by a medical practitioner. At the same time the druggists have been advised to buy such preparations only from reliable manufacturers. I am informed that this measure was due to the increasing tendency of the public to make use of thyroid extracts and similar remedies without medical advice, a practice which has led to some serious accidents on account of too large doses having been taken. A second motive for this order which will meet with the approval of the medical profession lies in the fact that it is very difficult to ascertain whether an organo-therapeutic preparation really contains the active principles which it should contain, as there are no simple chemical tests to prove or disprove the statements made by manufacturers regarding the composition and the value of their products.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Forcible Introduction of Sanitary Reforms into Cuba.

THE Special United States Commissioner who has been almost continuously in Cuba in an official capacity since hostilities were suspended, says that in Santiago may be seen in full operation the work which the Government of the United States has been impelled to undertake. Here may be studied the character of the forces upon which the people of the United States must rely in the work of reconstruction now in progress. The machinery of government is running with a fair degree of smoothness, and the men responsible for it, from the humblest official to the commander of the province, understand their business and are masters of the situation. The disagreeable smells of the typical Cuban city are less pronounced in Santiago, while whitewash, limewash, fresh paint, and all sorts of disinfectants have deodorised the surrounding atmosphere and made the old town habitable. The streets are no longer used as sewers, and the unhappy individual who violates the law and escapes the lash of the sanitarian's whip is compelled to work on the streets for 30 days. This official and his 106 men dressed in spotless white and 32 good United States mule teams and carts have dug out from the streets of Santiago the filth of ages and are now able to keep them clean. Every day, by the aid of that great disinfectant petroleum, the garbage of the city is burned. The work of sanitation is not confined to the streets, but it extends to the dwelling-houses, the shops, and buildings of all kinds. Indeed, the campaign against dirt and disease has been as sharp and hot as the charge on San Juan Hill, and it has been equally productive of results. The resistance on the part of the inhabitants is quite as stubborn, perhaps more so, than that of the Spanish soldiers to the American forces around Santiago. The doors of houses had to be smashed in; people making sewers of the public thoroughfares were publicly horsewhipped in the streets of Santiago; and eminently respectable citizens were forcibly brought before the commanding general and sentenced to aid in cleaning the streets which they were in the habit of defiling. The campaign ended in complete surrender to the authorities, and the inhabitants of Santiago, regardless of class, have had their first object-lesson in the new order of things introduced by the war. On looking backward five months, picturing Santiago in July and comparing it with the more hopeful condition existing on all sides at the present moment, it is easy to see the omens which point to the coming prosperity of the whole island under intelligent and honest government.

The New York State Board of Medical Examiners.

The report of a committee states that of the 809 applicants before the Board, representing the State society, 29·9 per cent. were refused. The rejections by topics were: anatomy, 55; physiology and hygiene, 41; chemistry, 67; surgery, 54; obstetrics, 62; pathology and diagnosis, 68; therapeutics, practice, and materia medica, 78. Among the New York graduates there was one for every three students. It was evident that these schools graduated better qualified men than other similar institutions in the United States. It had been decided to hold hereafter only four examinations instead of five each year. The faculties of the various medical schools had been asked to furnish 30 questions on every branch taught in these schools for the use of the question committee. It had been proposed to alter somewhat the plan of examinations—viz., separating pathology and diagnosis, divorcing medical practice from materia medica and therapeutics, and grouping on one sheet questions on chemistry and hygiene.

The Report of the Commission on the Conduct of the War.

The following is a summary of the finding of the Commission as to the Army Medical Department: At the outbreak of the war the medical department was, as to men and materials, altogether unprepared to meet the necessities of the army called out. As the result of a generation of contracted and contracting methods of administration it was impossible for the department to operate largely, freely, and without due regard to cost. In the absence of a special corps of inspectors and the apparent infrequency of inspections by chief surgeons and of official reports of the state of things in camps and hospitals there was not such investigation of the sanitary conditions of the army as is the first duty imposed upon the department by the regulations. The nursing force during the months of May, June, and July was neither ample nor efficient—reasons for which may be found in the lack of a proper volunteer hospital corps, due to the failure of Congress to authorise its establishment and to the non-recognition in the beginning of the value of women nurses and of the extent to which their services could be secured. The demand made upon the resources of the department in the care of the sick and wounded was very much greater than had been expected and consequently in like proportion these demands were imperfectly met. The department being powerless to transfer supplies from point to point except through the Quartermaster's Department, it was seriously crippled in its efforts to fulfil the regulation duty of "furnishing all medical hospital supplies." Shortcomings in administration and operation may justly be attributed in large measure to the hurry and confusion incident to the assembling of an army of untrained officers and men, 10 times larger than before, for which no preparation in advance had been or could be made because of existing rules and regulations. Notwithstanding all the errors of omission rather than commission which were manifest, a vast amount of good work was done by medical officers, high and low, regular and volunteer, and there were usually few deaths among the sick and wounded.

Reserve Corps of Nurses Needed.

The Army Investigating Committee recommend the following improvements in the medical service: A larger force of commissioned medical officers; authority to establish in time of war a proper volunteer hospital corps and a reserve corps of selected trained women nurses, ready to serve when necessity shall arise but under ordinary circumstances owing no duty to the War Department except to report their residence at determined intervals; a year's supply for an army of at least four times its actual strength of all such medicines, hospital furniture, and stores as are not materially damaged by keeping, to be held constantly on hand in the medical supply depôts; the charge of transportation to such extent as will secure prompt shipment and ready delivery of all medical supplies; the simplification of administrative "paper work" so that medical officers may be able to discharge their sanitary and strictly medical duties; and the securing of such legislation as will authorise all surgeons in medical charge of troops, hospitals, transports, trains, and independent commands to draw from the Subsistence Department funds for the purchase of such articles as may be necessary to the proper treatment of soldiers too sick to use the regular army rations—this to take the place of all commutation of rations of the sick now authorised. Convalescent soldiers travelling on furlough should be furnished with transportation, sleeping-berths, or state-rooms, and $1.50 per diem for subsistence in lieu of rations, the soldier not to be held accountable for this amount.

State Care of Consumptives.

At the recent meeting of the New York State Medical Society a resolution was passed urging the present legislature to adopt a measure for the establishment of a State hospital for consumptives. It appears that 13,000 lives are lost annually in the State of New York from pulmonary tuberculosis. Only one State in the Union—namely, Massachusetts—has a State hospital for consumptives. It was urged that ideal isolation can only be secured by State care, and that segregation should be employed among the poor by establishing special hospitals near the large centres of population. Thus far the cottage plan of treatment in the Adirondack Mountains in the northern part of the State has proved most successful and it is in this region that it is proposed to establish the State hospital for this class.

Feb. 19th.

NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

The Annual Meeting of the New Zealand Branch of the British Medical Association.

THE annual meeting of the above association commenced its sittings in Auckland on Jan. 3rd and terminated on Jan. 10th. The members met in the large room connected with the University College buildings which had been kindly placed at the disposal of the Auckland section. The gathering was under the presidency of Dr. Scott, while Mr. Hope Lewis acted as president of the local branch and Dr. Pabst as secretary for the annual meeting.

The city was besieged with visitors from all parts of New Zealand. Accommodation was consequently extremely difficult to obtain and prices as a result ranged high. Other attractions were the Auckland Exhibition, which had been opened but a short time previously by his Excellency, Lord Ranfurly, and the fact that the Auckland Racing Club held its annual meeting during the conference week. Notwithstanding these additional allurements, the attendance of members at the medical conclave was not as numerous as had been anticipated, but it nevertheless brought together a fair sprinkling of medical men from the North Island. The members of the Auckland section made the visitors' stay in their city most enjoyable. Aided by perfect weather the latter were enabled to thoroughly appreciate all the outdoor relaxations which were available, and they were not a few.

Auckland is certainly from a picturesque point of view the most beautiful city in this colony. The glorious Hauraki Gulf studded with its fantastically shaped islands, the beautiful blue water, the magnificent foliage of native trees everywhere to be seen all tend to impress one most favourably. From the summit of Mount Eden (an extinct volcano) a view is obtained which stretches from the east to the west coast of the North Island and in my opinion is not to be surpassed for loveliness in the southern hemisphere, with perhaps the exception of the harbour of Vavau. Auckland was decked in its gayest apparel on the opening day of the medical meeting. The harbour was brilliant with bunting. A boat race took place in the afternoon between the Maories and the man-of-war's-men from H.M.S. *Tauranga* and *Royal Sovereign*. The Maories won easily and a war dance in honour of their victory concluded the day's sport.

The agenda paper, owing to unforeseen circumstances, had to be altered and accordingly Mr. Hope Lewis opened the meeting with an excellent paper on Cases of Abdominal Section—a paper characterised by methodical arrangement of the various types of cases and a carefully prepared description of the minor details associated with each case. These details of operative work were much appreciated and an interesting discussion ensued in which Dr. Graham Campbell, Dr Cleghorn, and Dr. Saunders took part. A hearty vote of thanks was accorded by the members present for the paper read.

On Wednesday evening the installation of the President for the ensuing year took place followed by the Presidential Address—a *précis* of which I append. The retiring President, Dr. Fell (Wellington) in vacating the chair thanked the members for their kindness during his term of office and at the same time paid a high tribute to the manner in which Dr. Graham Campbell (Christchurch) had carried out the duties of general secretary. There is no doubt that the medical profession of this colony is very much indebted to Dr. Campbell for the untiring industry which he has displayed since his election to this post. He certainly possesses all those qualities which tend to make an excellent secretary and he assuredly exercises those qualities in a most satisfactory manner.

Dr. Scott, the president for the coming term, then took the chair and delivered his inaugural address, his subject being Sanitation and the Public Health. At considerable length he enumerated and criticised the laws of Great Britain and the colony concerning public health and complained of the lack in New Zealand of administration and the want of a controlling and advising body, such as the central board was in Great Britain and should be in New Zealand. The President contended that the mode of appointment of health officers and inspectors of nuisances was in a very unsatisfactory state in the colony, because these appointments were not compulsory, were not subject to the approval of the Central Board of Health, and were not made under any regulation issued by that body, and the tenure of office was insecure. In concluding his address Dr. Scott said: "There is everywhere a lack of order and method and a want of unity in the management of sanitary affairs which have brought about the culpable laxity in administration. The remedies for such a state of affairs must necessarily be directed to the correction of the shortcomings of the laws and of their methods of administration. It is a recognised fact that no law can be efficiently carried into effect unless its value and importance are understood and appreciated; therefore, my first recommendation would be—educate the public by means of: 1. The instruction of the children in the State schools. This is being done to a slight extent in the primary schools, but it is remarkable that no such instruction is given in the secondary schools. 2. Through the formation of societies somewhat after the pattern of ambulance societies which would arrange for periodical lectures and demonstrations in sanitary matters. 3. Through the press, which would then in its reports of the foregoing even more freely than heretofore give its valuable aid in creating an interest in the subject. 4. Through the New Zealand University, by inducing it to follow the example of Cambridge in 1875 and copied by, I believe, all the medical corporations in Great Britain since that time, and to grant, as they do, diplomas and degrees after a full course of instruction and examination in sanitary science. We should then have an educational force acting vigorously among us and without a break from the lowest to the highest grades, which would eventually compel the authorities to value each human being at some 38 times the value of swine. The work of educating the masses requires much time and as immediate reform is urgent it is absolutely necessary to call upon the authorities to at once enforce the present Health Acts; then, without any amendment of the laws, the Central Board could have at its disposal an efficient staff of medical and other officers to carry out their requirements which was the function for which it was established. The board, on receipt of the annual reports of the local authorities (if it carried out the trusts committed to it), would through its officers, investigate the causes of exceptional sickness within the district of any local board and would thereupon issue such orders or instructions as might be necessary for the protection of the health of the community. The members of the Central Board, using the powers which they already possess, would soon find out where the present machinery is faulty and could ask for such amendments in the law as might be necessary for the better protection of the public with an absolute certainty that their reasonable demands would be complied with. There are, however, some amendments clearly required without further delay, such as: (*a*) the compulsory amalgamation of small road boards so as to form boards of health whose administration would at the same time be both economical and efficient; (*b*) provision that a competent staff of officers shall be appointed by all local boards subject to the approval of the Central Board—these officers to be strictly independent of the local board and to be responsible solely to the Central Board who should authorise the payment of part or all of the salaries of these officers on being satisfied of the efficient performance of their duties and on these terms alone; and (*c*) in each of the four centres of population there ought to be appointed a medical officer of health whose services should be entirely at the disposal of the sanitary authorities but who might have other suitable duties assigned to him and be by virtue of his office an official investigator in all cases of inquest, a public bacteriologist, pathologist, and analyst, and possibly also one of the certifying practitioners under the Lunacy Acts. This officer might also advise rural medical officers and supervise their work. It might be well to consider in connexion with such a scheme whether the districts of the present hospital and charitable aid boards would be advantageous for the local administration of public health affairs and whether these boards, with or without some slight amendments of their constitution, would be suitable as either intermediate or local boards of health. The present local boards, under such circumstances, could still exercise minor jurisdiction in sanitation within their parochial districts. The Central Board should be so constituted that it would be actually the supreme authority in all matters relating to public health. This board should be required to exercise full and direct control over all local boards and should be granted power to compel such boards to carry out all works necessary for the preservation of health, inclusive of those of such magnitude as sewerage and water-supply. The local boards, enlarged in area and powers, should be able on their part to direct and control the parochial boards subject to appeal to the Central Board. Our Government, as I am fully persuaded, is earnestly desirous of furthering the welfare of the community in every particular. It cannot carry out this object of its existence in any better manner than by completing the organisation I have faintly sketched out by forming a Ministerial department of public health. We have departments of justice, defence, and education, all doing important and valuable work, but none is of such vital importance to the welfare of the community as would be a department of public health. This proposition is so evident as to require no argument in its favour, as all appreciate the commercial and physical advantages of security of health. In 1869 a Royal Commission was appointed in England which reported in 1871 that 'the administration of sanitary laws should be made uniform, universal, and imperative throughout the kingdom; that all powers requisite for the health of towns and country should in every place be possessed by one responsible local authority kept in action and assisted by a superior authority.' All sanitary legislation in Great Britain since that time has been initiated in furtherance of the propositions there set forth. The recent British Local Government Acts are calculated to carry out this principle to a greater extent than any preceding enactment. We in this colony cannot go far wrong if we implicitly follow this same policy and even carry it further than Great Britain by the establishment, as I have already proposed, of a department of sanitation. Notwithstanding the 70 Acts and amendments passed relating to sanitation there has been no practical advance made in our sanitary legislation since 1876. The Municipal Corporations and Local Authorities Bills now under the consideration of the Ministry do, however, indicate an attempt at progress as they provide for—(1) county councils acting as rural boards of health in lieu of road boards; (2) simplification and amplification in the process of making by-laws; (3) the authority for the Governor to frame and gazette model by-laws; (4) the better attention to the prevention of overcrowding and over-building; (5) and, finally, a more readily available means of compelling the carrying out of sanitary measures notwithstanding the neglect of a local board. This provision is taken from the Local Government Act, 1890, Victoria, and reads: '1. If any council constituted under this Act in the opinion of the Governor wilfully refuse to act in conformance or exercise of the duties or powers respectively reposed and vested in it by this Act, or in the like opinion substantially so refuse to act, the Governor may make such provision as he thinks fit for the due performance of such duties and powers either by himself or any other person. 2. In particular the Governor shall have and may exercise all the powers of such council to make, levy, and recover rates and to expend the same.' These are valuable amendments. Nevertheless, the provisions of these Bills would not affect materially the unsatisfactory position of sanitary administration as there is no provision for compelling the Central Board to do its duty. All the duties and obligations of the local boards which are optional in our present Acts remain so in these Bills and therefore would not come within the penal provisions. I think our branch would be doing an admirable work were it to devote time during the present year to revising the sanitary sections of the Municipal Corporations and Local Authorities Bills. In the main we must admit that the responsibility for the present unsatisfactory state of the administration of sanitation in this colony must rest with the members of our profession who having the requisite knowledge and the special opportunities for observation and comparison have failed to direct attention to reforms with that force which is so necessary to move public opinion. It might well have been objected to any proposal for reform that if we were satisfied the public might rest content. We have not done our duty in the past, but in the face of the examples set us by other communities we should delay no longer or speak with uncertain sound, but insist that in the interests of the community reform must come and come speedily. We must rise to our responsibilities and no longer be content with spasmodic and individual action, but set ourselves unitedly and strenuously to bring about such changes as our experience has clearly shown to be necessary, and in so doing we shall be carrying out one of the primary objects of our association."

Jan. 16th.

Obituary.

FREDERICK ASHTON HEATH, M.R.C.S. ENG., L.S.A.

MR. F. A. HEATH, one of the consulting surgeons of the Manchester Royal Infirmary, died on March 2nd, after a long and painful illness, at the age of 69 years. He was born in Manchester, where his father was a well-known practitioner, and he lived and died in the city of his birth. He received his medical education at the Manchester Royal School of Medicine, now an important department of Owens College, and this course was supplemented by study at Guy's Hospital and in Paris. Mr. Heath was for many years one of the surgeons of the infirmary and at the "fixed period" of 60 years became one of the consulting staff. He was a careful and judicious surgeon and a successful operator His kindness of heart endeared him to his patients, whether in the Infirmary wards or in their own homes, and though his retiring disposition and great modesty prevented him from taking so prominent and public a position as he might have done, these qualities, together with his cheery and kindly manner, gained him many friends, by whom his death will be greatly regretted He was buried at Prestwich Church prior to which a service was held at the Manchester Cathedral, where he had been an attendant from boyhood In addition to the members of his family there were present representatives of the Infirmary Board with many of his old colleagues on the infirmary staff and a large number of medical and lay friends

FOREIGN UNIVERSITY INTELLIGENCE — *Basle*. Dr Garré of Rostock has declined the invitation to the chair of Surgery in succession to the late Dr Socin —*Berlin* - Dr Paul Jacob assistant in the First Medical Clinic, under Professor von Leyden, and Dr Max Rothmann have been recognised as *privat docenten* of Medicine, Dr Finkelstein of the Charité as *privat docent* of Children's Diseases, and Dr Grabower as *privat docent* of Laryngology —*Bologna* - Dr Orazio Modica has been recognised as *privat docent* of Forensic Medicine.—*Catania* Dr Annibale Costa has been recognised as *privat docent* of Surgical Pathology —*Florence*. Dr O Baduel has been recognised as *privat docent* of Medical Pathology —*Freiburg* Dr Hugo Sellheim has been recognised as *privat docent* of Midwifery and Gynæcology —*Jurieff* (*Dorpat*) Dr Czermak has been promoted to the Ordinary Professorship of Comparative Anatomy Histology, and Embryology —*Munich* Dr von Rothmund, Professor of Ophthalmology, is about to retire —*Naples* Dr Gatta has been recognised as *privat docent* of Medical Pathology, Dr O Colucci as *privat docent* of Psychiatry, Dr C Ghillini as *privat-docent* of Orthopædics, and Dr Pietravalle as *privat-docent* of Midwifery and Gynæcology Dr Pietro Castellino of Padua has been appointed Professor of Medical Pathology —*Pavia* Dr A Monti of Palermo has been appointed Professor of Pathological Anatomy, Dr Carlo Ceni has been recognised as *privat docent* of Neurology, Dr Cosimo Binda as *privat docent* of Forensic Medicine, and Dr Cesari Paderi as *privat docent* of Pharmacology and Materia Medica —*Rio de Janeiro* Dr Marcos Cavalcanti has been appointed to the chair of Clinical Surgery in succession to Dr O Bulhões, deceased Dr Domingos de Góes e Vasconcellos has been appointed to the chair of Operative Medicine, vacant by the promotion of Dr. Cavalcanti —*Rome* Dr Severino Boezio Piergili of Genoa has been recognised as *privat docent* of Otology Dr Roberto Binaghi has been recognised as *privat docent* of Surgical Pathology and Dr Constantino Gorini as *privat docent* of Experimental Hygiene —*Rostock* Dr Kobert formerly Professor in Iurieff (Dorpat) has been appointed to the chair of Pharmacology and Medical Chemistry in succession to Dr O Nasse, resigned —*Strasburg* Dr Adolf

Magnus-Levy, formerly of Berlin, has been recognised as *privat-docent* of Medicine.—*Vienna:* Dr. W. Pauli has been recognised as *privat-docent* of Internal Medicine.—*Würzburg:* Dr. Fick, Professor of Physiology, is about to retire; Dr. Andreas Rosenberger, Extraordinary Professor of Forensic Medicine, has retired.

MEDICAL MAGISTRATE. — Mr. E. F. Eliot, F.R.C.S. Edin., L.R.C.P. Edin., F.F.P.S. Glasg., of Southampton, has been appointed a magistrate for the County Borough of Southampton.

THE MEDICAL OFFICER OF HEALTH OF WILTSHIRE.—Dr. Maxwell Ross, who was recently appointed medical officer of health of Wiltshire, has decided not to accept the appointment. In accordance with the terms of the resolution recently passed by the Wiltshire County Council the post has been offered to Mr. John T. Thomas, the medical officer of health of Leicestershire and Rutland combined districts.

COUNTY LABORATORY FOR GLAMORGANSHIRE.—At a recent meeting of the Sanitary Committee for Glamorganshire it was decided to ask University College, Cardiff, to utilise the laboratory for instruction in public health work, and to ascertain whether the Cardiff Corporation wished to have a share in the laboratory. It was also decided that bacteriological examinations of water should be made gratuitously, but only when the samples were submitted by registered medical practitioners or medical officers of health. Various fees will be charged for other examinations.

UNIVERSITY OF CAMBRIDGE. — The Medical Board propose a change in the regulations for the M.C. degree whereby Masters of Arts who have become legally qualified to practise surgery may apply for admission to take the degree on account of their original contributions to the advance of the art or science of surgery.—At the Congregation on March 2nd the following medical and surgical degrees were conferred:—M.B. and B.C: F. A. Godson, B.A., St. John's; A. W. Daniel, B.A., Emmanuel; R. J. Wilson, B.A., Emmanuel. M.B.: A. G. Butler, B.A., St. John's.

PRESENTATIONS TO MEDICAL MEN. — At the fortieth anniversary dinner on Feb. 21st of the Loyal Albion Lodge, Independent Order of Oddfellows, Manchester Unity (West London district), Mr. Frederick Henry Alderson, M.D. St. And., late surgeon to the lodge, was presented upon his retirement with a testimonial consisting of a gold jewel emblematical of the Order and an address artistically wrought, being surmounted by the symbols of the Order, and an excellent photograph of himself in the centre, as tokens of grateful recognition of his 30 years' faithful service to the lodge.—The members of the St. John Ambulance class at Newlyn, Cornwall, have presented Mr. A. R. Field Evershed, L.R.C.P. Lond., M.R.C.S. Eng., of Penzance, with a copper pipe-rack suitably inscribed as a mark of their appreciation of his services as honorary instructor.—The members of the St. Agnes (Cornwall) branch of the St. John Ambulance Association gave a complimentary dinner recently to Mr. William Whitworth, M.R.C.S. Eng, L.S.A., in appreciation of his services as honorary instructor of the class.

Parliamentary Intelligence.

HOUSE OF COMMONS.

TUESDAY, FEB. 28TH.

Convalescent Homes for Soldiers.

MR. WYNDHAM, replying to a question addressed to him by Captain NORTON, said that in the opinion of the Army Medical Department there was not the same necessity for establishing convalescent stations for soldiers in Ireland as existed in England because the barracks were mostly situated among small populations and healthy surroundings. It was thought that the barracks at the Curragh, Holywood, and Queenstown would afford the necessary change for sick soldiers quartered at Dublin, Belfast, and Cork respectively.

Hours of Labour in Bakehouses.

Mr. WOODS introduced at this sitting a Bill to restrict the hours of labour in bakehouses to 48 per week.

THURSDAY, MARCH 2ND.

The Medical Service of the Volunteers.

Dr. FARQUHARSON asked the Under Secretary of State for War whether his attention had been called to the unsatisfactory condition of the medical service of the volunteers, more particularly to t anomalous position of the brigade bearer companies; and whether was proposed to so organise the volunteer medical service as to assimil it to the regular medical service of the army both as regards rank the medical officers and the organisation of the Volunteer Medical Sta Corps and the brigade bearer companies and thereby render it effecti as one of the departments of the volunteer force.—Mr. POWE WILLIAMS, replying for Mr. WYNDHAM, said: An increased establis ment has been given to all companies of the Volunteer Medical St Corps in order to complete the *personnel* for transport sections. A allowance will be given to enable them to practise transport duti There is no intention to make an alteration in the rank of volunte medical officers. The question of the reorganisation of the volunte infantry brigade bearer companies is under consideration.

The Vaccination Question.

Mr. STRACHEY asked the President of the Local Government Boa whether in view of the objections felt by many medical men at havi their patients visited by the public vaccinator he would take in consideration the desirability of paying for vaccination by the fami medical attendant.—Mr. CHAPLIN: I have no information to the effe that objections are felt by many medical men at having the patients visited by the public vaccinator. The duty of the publ vaccinator to visit the home of an unvaccinated child does not ari until the child has attained the age of between four and fi months unless the parent requests him to visit the home at earlier date. There is therefore ample opportunity for the priva practitioner to perform the operation if it is desired. The sugge tion of the hon. Member was fully discussed during the pa sage of the Bill last year but was rejected by a majority of mo than two to one, and I see no reason for altering that decision now.

Mr. CHANNING asked the President of the Local Government Board (with reference to a letter of the Local Government Board addressed la December to one of the vaccination officers of the Reading Board Guardians in which it was stated that it would be contrary to th Board's practice to advise an officer of a board of guardians withou reference to the guardians in a matter in which the guardians hav jurisdiction, whether the matter submitted to the Local Governmen Board and touched upon in their reply was action by the vaccina tion officer in prosecuting defaulters under the Vaccination Acts; (whether vaccination officers were to understand from this letter that i interpreting the instructions to vaccination officers in the fourt schedule to the general Vaccination Order of Oct. 18th, 1898, in su section (*d*) of section 6 of those instructions and elsewhere that it wa their duty in the first place to take the orders of the guardians as t prosecuting or not prosecuting defaulters, or to abstain from prosecut ing any defaulter if so ordered by the guardians; (3) whether, for severa years before the Vaccination Act, 1898, the Local Government Boar had left the boards of guardians free to decide whether prosecution were to be undertaken or not and had repeatedly addressed to th boards copies of the Evesham letter urging the boards not to repea prosecutions; and (4) whether he would forthwith send a circular to al vaccination officers that they were to act according to the instruction given in the Reading letter referred to in this question; and with the admitted practice which the Local Government Board had now allowe for several years past.—Mr. CHAPLIN: The hon. Member is under a misapprehension as to the correspondence to which he alludes. No such letter as that referred to in the question was written by th Local Government Board in December last. But in January 1898, one of the vaccination officers of the Reading Union wrot to the Board asking for their advice in the matter of vaccinatio without specifying any particular point and the reply to the letter wa to the effect stated in the question. As regards the second and fourth paragraphs it will be obvious that that letter had no bearing on th instructions to vaccination officers in the Vaccination Order o October, 1898, as it was written nearly nine months prior to the issue o the Order. As regards the third paragraph, under the regulations whic were in force until the present year it was the duty of the guardian to cause proceedings to be taken against persons in defaul under the Vaccination Acts and for this purpose to give directions t the vaccination officer to institute and conduct the proceedings. I was the practice of the Board to point out to the guardians that it wa their duty to give directions to the vaccination officer accordingly. I was decided in the case of Bramble *v.* Lowe that notwithstanding th regulations then in force the power of taking proceedings was vested i the vaccination officer under the Vaccination Acts without any dire tions from the guardians which were held to be superfluous and havin regard to that decision and to the opinions given by the law officers the Crown the Board have not in their new Order imposed any dut either on the guardians or vaccination officer as regards the institutio and conduct of proceedings.

Examinations for Sanitary Inspectors.

Mr. CHAPLIN, replying to a question by Mr. HOBHOUSE, said that a association had been formed with the concurrence of the Local Gover ment Board for holding examinations for persons desirous of obtainin certificates of competency for the office of sanitary inspector. inspector of nuisances. One of the objects of the association was t prescribe such course of study and technical training as might calculated to ensure the fitness of persons desirous of qualifying fo these offices. Several bodies, some of whom provide instruction fo those who desire to become sanitary inspectors, would be represente on the examination board and representatives might be elected by suc additional bodies as might from time to time be approved by th Local Government Board.

Tuberculosis.

Mr. CHANNING asked the First Lord of the Treasury whether, havin regard to the repeated expressions of opinion by the Central an Associated Chambers of Agriculture, British Dairy Farmers' Associ tion, and many other representative bodies to the effect that th questions relating to tuberculosis should be dealt with by the State i legislation for the whole country, Her Majesty's Government woul introduce a Bill or Bills to meet this desire and secure unifor administration throughout the United Kingdom.—Mr. BALFOUR: Th Government are not at present prepared to propose legislation on th subject.

Vivisection.

Mr. MACNEILL asked the Home Secretary whether he was aware tha at an anti-vivisection meeting held at Bradford on Sept. 30th las

Dr Kerr, speaking against the proposed withdrawal of licences granted to vivisectors, said the effect of the proposal would be to increase the number of illegal experiments on the bodies of living animals and that such experiments were performed by many of his fellow practitioners at Bradford as it was necessary in the cause of science that such experiments should be made, whether he was aware that Dr Kerr stated that Dr Hines of Horton-road, Bradford, was the only vivisector in Bradford who carried out experiments in vivisection under the licence required by law, and that Dr Hines, who was present, stated that he had performed hundreds of vivisections and should continue to do so; whether he was aware that the secretary of the Anti-Vivisection Society produced a list of licensed vivisectors on which the name of Dr Hines did not appear; and whether, in view of these facts, he intended to take any and what steps for the enforcement of the law against the practice of unlicensed vivisection.—Mr JESSE COLLINGS replied: The Secretary of State believes that at a somewhat excited meeting at Bradford on the date mentioned statements to the effect suggested were made. His attention was drawn to the matter at the time; he caused inquiry to be made but he could not elicit any clear statement of what was actually alleged or any evidence of illegal vivisection being performed by Dr Hime, not Hines. There are, therefore, no steps which he can take in the matter. I may add that it should be remembered that performing upon an animal an experiment calculated to give pain without a licence is an ordinary offence which any person may prosecute.—Mr MACNEILL asked the Home Secretary whether his attention had been called to the interpretation put by the Government inspector of vivisection operations on the effect of the Act when he stated in his preface to the last returns that the certificates dispensing with the use of anæsthetics made it obligatory on the holder not to use them even should he desire to do so and when he himself believed that the experiment could be carried on under anæsthetics, and whether he would take this interpretation of the Act by the Government inspector under his consideration.—Mr JESSE COLLINGS said: The Secretary of State thinks that the hon. Member has entirely misconceived the meaning of the statement to which he refers. Perhaps I may explain the apparent difficulty. The Act lays down that experiments such as those in question can only be performed without anæsthetics by a person holding a certain certificate. If the experiment is to be performed under or partly under, anæsthetics the certificate required is quite different. The operator referred to possessed the former but not the latter certificate. Therefore, by using anæsthetics in his anxiety to avoid causing even the slightest pain to the animal he committed a slight technical irregularity which the inspector in accordance with the usual practice noticed in his annual report.

Physical Drill in the Army.

Mr GEORGE WYNDHAM, Under Secretary for War, in making the annual statement with regard to the condition of the army, said on the subject of recruiting: I am sorry to say that of the recruits who presented themselves 35 per cent. were rejected on medical grounds. I think that that is rather an alarming figure. It may give us just cause for apprehension, not only in respect of the welfare of the army, but of the people themselves. A good many of these rejections were due to bad teeth and it is quite astonishing to learn the number who were rejected because they lacked general development. It occurs to me that in schools largely supported out of public funds it may not be impossible to get the children to take some elementary precautions to preserve their teeth while it would also be a good thing to introduce into the schools that system of physical drill which Colonel Fox thinks has done so much for the recruits of the British Army. What it has done for the recruits may be gathered from the large percentage of recruits who were under standard but who attained the standard within a short time and this fact was simply due to these exercises. Of the recruits re-measured in January who had joined since October 43 per cent. had reached the standard; of the 'specials' who joined before June 30th 73 per cent. had reached the standard; and of 'specials' who joined before 1898 90 per cent. had reached the standard, and some of those 'specials' are now, on account of their abnormal muscular development, teaching gymnastics in our gymnasia.

FRIDAY, MARCH 3RD.

Notification of Infectious Disease.

On the motion of Sir FRANCIS POWELL a Bill was introduced to extend the Infectious Disease Notification Act, 1889, to districts in which it has not been adopted.

MONDAY, MARCH 6TH.

The Supply of Medicine to Irish Workhouses.

Mr M'CARTAN asked the Chief Secretary to the Lord Lieutenant of Ireland (1) whether his attention had been called to a paragraph published in the Dublin *Freeman's Journal* of March 2nd, under the heading "Local Government Board Medicine Tender Forms"; (2) whether he was aware that the paragraph contained a copy of a resolution adopted unanimously by a board of guardians protesting most emphatically against the use of these forms as prejudicial to the purchase of certain medicines in Ireland; (3) whether these forms quoted from the price-lists of English firms and in certain cases contained the fancy trade-mark of English firms; and (4) whether in the encouragement of Irish industries these forms would be discontinued and boards of guardians and district councils allowed to purchase with Irish money these drugs, medicines, and instruments from Irish firms in Ireland.—Mr GERALD BALFOUR replied that the answer to the first and second paragraphs of the question was in the affirmative. In the Local Government Board's prescribed list of medicines 11 out of the total of 416 articles given therein were quoted from the price-list of an English firm—Messrs. Burroughs and Wellcome—the strength of the preparation being stated in each case. These few articles had been added to the 405 preparations of the British Pharmacopœia included in the list as being articles of well-established reputation. There was no foundation for the complaint contained in the resolution that the inclusion of the few preparations referred to in the Board's authorised list would be prejudicial to Irish manufacturers and the Local Government Board had reason to believe that any list which excluded the 11 preparations of Messrs. Burroughs and Wellcome would be considered incomplete by the medical profession. These articles had received the approval of the Royal College of Physicians of Ireland. No objection had been received from the Irish drug trade respecting the Local Government Board's prescribed list of medicines.

Sale of Food and Drugs Bill.

At this sitting there was a debate on the motion for the second reading of the Sale of Food and Drugs Bill promoted by the Government. Mr. WALTER LONG, President of the Board of Agriculture, in making the motion explained in detail the provisions of the Bill and the objects of the Government in promoting it. He laid down two propositions. One was that they ought not to interfere by legislation with a legitimate industry which produced a wholesome and valuable article of food in great demand by the poorer classes of the country especially, and which they were entitled to have and to buy freely and openly, so long as it was sold in a straightforward manner; and the other was that the law of the land as now found on the statute book must be obeyed and carried out and that if it was possible to secure it trade must be conducted on honest and honourable principles. Taking these two propositions as conditions antecedent to legislation he thought it would not be difficult for Parliament so to alter the law by tightening it up in one or two directions and by conferring some fresh powers on the Board of Agriculture as to meet all the requirements of the case. It was proposed by the Bill that samples should be taken at the port of debarkation of certain articles of dairy produce such as butter, cheese, and milk and power was sought to proceed against the people who were responsible for the introduction of adulterated articles. With regard to the home trade, the Bill proposed that the duty of carrying out the Acts should rest with the local authority as at present but that the Board of Agriculture should have power to guide the local authority and urge it to carry out its powers. If the local authority were found to be in default, then it would be for the Board of Agriculture to do the work and charge the cost of the proceedings to the local authority. It was proposed that the limit of butter fat in margarine should be 10 per cent. which would not interfere with the manufacture of the best descriptions of margarine, but it was not proposed to stop the colouring of margarine which was coloured in the same way as butter, cheese, and milk to make it look attractive.—Mr LOGAN, seconded by Sir CHARLES CAMERON, moved the rejection of the Bill and after several other members had spoken the debate was adjourned.

TUESDAY, MARCH 7TH.

The London Water Question.

Mr HARRY SAMUEL asked the President of the Local Government Board whether in the event that the Metropolis Water Bill did not pass into law in time to prevent a recurrence next summer of the water famine in East London, he would take temporary measures to prevent a scarcity of water in that district of the metropolis.—Mr CHAPLIN replied: I do not quite understand what are the temporary measures to which the hon. Member refers or why he should assume that the passage of the Bill may be delayed. Nothing that I am aware of except the completion of certain connexions between the works of different companies can ensure the inhabitants of East London against recurrence of scarcity in the event of a similar drought to that of last summer and every effort will be made to promote the passing of the Bill.

WEDNESDAY, MARCH 8TH.

The Conscientious Objector.

An attempt was made by Mr Boulnois at this sitting to get a second reading for his Bill to repeal the Conscientious Objector Section of the Vaccination Act of last year. The attempt, however, failed and the order was postponed until Wednesday, March 22nd.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ANDREWS, RICHARD JAMES, M.R.C.S., L.S.A., has been appointed Medical Officer of Health by the Urban District Council of Heavitree.

BARNES, GEORGE, M.R.C.S., L.R.C.P. Edin., L.S.A., has been re-appointed Medical Officer of Health for Chard.

BELDING, D. T., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the East Dereham Urban District Council.

BROWN, R., M.B., B.S. Durh., has been re-appointed Medical Officer of Health by the Blaydon Urban District Council.

BRYNE, P. A., M.D., B.S. Lond., F.R.C.P., M.R.C.S., has been appointed Medical Officer for the Christchurch Sanitary District, Parish of St. Marylebone, London.

CHISSON, H., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Medical Superintendent to the Hospital for the Insane, Goodna, Queensland.

COCKS, O. C., M.D. St. And., M.R.C.S., has been appointed Government Medical Officer and Vaccinator for the District of Wentworth, New South Wales, vice H. Breton, resigned.

COOPER, A., F.R.C.S. Eng., has been appointed an Honorary Consulting Physician to St. Mary's Hospital, City-road, London.

CORBETT, CHARLES, L.R.C.P. Lond., M.R.C.S., has been appointed Public Vaccinator for the Caldicott District by the Chepstow Board of Guardians.

COUNSELLOR, W. P., M.D. Durh., L.R.C.P. Irel., M.R.C.S., has been re-appointed Medical Officer of Health by the Clitheroe Rural District Council.

DUNCAN, WM., M.B., C.M. Glasg., has been re-appointed Medical Officer of Health by the Clay Cross Urban District Council.

FLOWER, FRED. J., M.R.C.S., has been re-appointed Medical Officer of Health by the Warminster Urban District Council.

Forster, Fred. C., M.R.C.S., L.R.C.P., has been appointed Assistant House Surgeon to the Royal Berkshire Hospital, Reading.

Freyer, J. K., *L.K.Q.C.P. Irel., L.R.C.S.*, has been appointed Government Medical Officer and Vaccinator for the District of Tenterfield, New South Wales, vice R. T. Morice, resigned.

Halford, A. C. F., M.B., Ch.B. Melb., has been appointed Resident Surgeon, Peak Downs Hospital, Clermont, Queensland.

Hart, J. W., M.B., Ch.M. Edin., has been appointed Government Medical Officer and Vaccinator for the District of Binpara, New South Wales, vice G. C. Cary, resigned.

Hoffman, A. H., M.D. St. And., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health by the Knighton Rural District Council, vice R. F. Cox, resigned.

Jones, F. F., M.R.C.S., has been appointed Medical Officer of the No. 2 Sanitary District of the Bath Union, vice H. C. Hopkins, resigned.

Jones, R. R., L R.C.P. Edin., M.R.C.S., has been appointed Medical Officer to the Bangor Post Office.

Kay, J. Graham, M.B., C.M. Edin., has been appointed Public Vaccinator for the Shirenewton District by the Chepstow Board of Guardians.

Kenny, A. S., M.R.C.S., has been appointed Medical Superintendent of the Government Sanatorium at Rotorna, New Zealand.

Kerr, J. L., M.D. Aberd., C.M., has been appointed Medical Officer for the Biddenden Sanitary District of the Tenterden Union.

Lawrence, A. G., M.D. St. And., M.R.C.S., L.S.A., J.P., has been appointed Public Vaccinator for Chepstow by the Chepstow Board of Guardians.

Mackenzie, E., M.D. Glasg., C.M., has been appointed Medical Officer for the Workhouse and the Cheadle Sanitary District of the Cheadle Union.

Mackinnon, Charles, M.A., M.B., C.M. Glasg., has been re-appointed Medical Officer of the South District of the Cirencester Union.

Miller, Victor, M.B., C.M. Edin., has been appointed Honorary Ophthalmic Surgeon to the North Ormsby Hospital, Middlesbrough-on-Tees.

Parr-Dudley, Arthur Dudley, L.R.C.P. Lond., M.R.C.S., L.S.A., been appointed Medical Officer and Public Vaccinator for the Fifth District of the Chipping Sodbury Union.

Pattinson, H. A., L.R.C.P. Irel., M.R.C.S., has been re-appointed Medical Officer of Health by the Seaton Urban District Council.

Spence, H., M.B., Ch.B. Melb., has been appointed a Public Vaccinator at Strathmerton, Victoria, Australia, vice B. B. Hoggan, resigned.

Thurnam, Herbert Leslie, M.A. Cantab., M.R.C.S., L.R.C.P., L.S.A., has been appointed Public Vaccinator for the whole District of Gravesend and Milton.

Treves, Frederick, F.R.C S., has been appointed an Emeritus Professor of Surgery to the London Hospital.

Turton, W. H., M.B., C.M. Edin., has been re-appointed Medical Officer of Health by Heanor District Council.

Walden, F. J., M.B., C.M. Edin., has been appointed Officer of Health for Sorell, Tasmania.

Williams, F. E., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer for the Sixth Sanitary District of the St. Neot's Union.

Woodroofe, R. P., L.R.C.S. Irel., has been appointed Medical Officer by the Eccleshill Urban District Council.

Vacancies.

For further Information regarding each vacancy reference should be made to the advertisement (see Index).

Blackburn and East Lancashire Infirmary, Blackburn.—Junior House Surgeon. Salary to commence at £50 per annum, with board, lodging, washing, &c.

Borough Hospital, Birkenhead.—Junior House Surgeon. Salary £60 per annum, with board and lodging, but no wine, spirits, or beer.

Charing-Cross Hospital, London.—Assistant Physician.

Chelsea Hospital for Women, Fulham-road, S.W.—Registrar for three years, subject to annual re-appointment. Honorarium 20 guineas per annum.

Chester General Infirmary.—Visiting Surgeon for two years. Salary £80 per annum, with residence and maintenance in the house.

Chorlton-upon-Medlock Dispensary, Manchester.—Resident House Surgeon, unmarried. Salary £100 a year, with furnished rooms and attendance.

County Asylum, Whittingham, Lancashire.—Junior Assistant Medical Officer, unmarried. Salary commencing at £100 per annum, increasing to £250 according to promotion, with furnished apartments, board, attendance, and washing.

Cumberland Infirmary, Carlisle.—Assistant House Surgeon for one year. Salary £40 per annum, with board, lodging, and washing.

Cumberland and Westmorland Asylum, Garlands, Carlisle.—Junior Assistant Medical Officer, unmarried. Salary £100 a year, with board and residence.

Dinorwic Quarry Hospital.—Assistant to act as Assistant Surgeon. Salary £150 a year, with half midwifery fees attended by him. Applications to Mr. Roberts, Dinorwic Quarry Hospital, Llanberis, North Wales.

Essex County Asylum, Brentwood.—Junior Medical Assistant Officer, unmarried. Salary £120 per annum, with board, residence, and washing.

Hospital for Consumption and Diseases of the Chest, Brompton.—Assistant Physician. Also Resident House Physicians.

Liverpool Dispensaries, 34, Moorfields, Liverpool.—Assistant Surgeon, unmarried. Salary £80 for the first year and £90 per annum afterwards, with board and residence.

Liverpool Northern Hospital.—Resident House Surgeon's Assistant for six months. Board and lodging provided.

London Hospital, Whitechapel, E.—Surgical Registrar. Salary £100 per annum.

Miller Hospital and Royal Kent Dispensary, Greenwich-road, S.E.—Junior Resident Medical Officer for six months. Salary £40 per annum, with board, attendance, and washing.

Monmouthshire Asylum, Abergavenny.—Third Assistant Medical Officer. Salary £100, increasing by two yearly instalments to £150, with board, lodging, and washing.

North Ormesby Hospital, Middlesbrough.—House Surgeon, non-resident, single. Salary £200.

Royal College of Physicians of London and Royal College of Surgeons of England Conjoint Laboratories.—Director of the Conjoint Laboratories.

Royal Infirmary, Sheffield.—Junior Assistant House Surgeon. Salary £50 per annum, with board, lodging, and washing.

Royal Hospital for Sick Children, Glasgow.—House Physician Salary £50, with board and washing.

Royal South Hants Infirmary, Southampton.—Assistant House Surgeon for six months. Gratuity £10, conditionally.

Royal Westminster Ophthalmic Hospital, King William-street, West Strand, W.C.—Assistant Surgeon.

Seamen's Hospital Society ("Dreadnought"), Greenwich, S.E.—House Surgeon for Branch Hospital, Royal Victoria and Albert Docks, E. Salary £50 per annum, with board and residence.

Staffordshire County Asylum, Stafford.—Junior Assistant Medical Officer, unmarried. Salary £100 a year, with furnished apartments, board, &c., and rising £25 per annum up to £150.

Staffordshire General Infirmary, Stafford.—Assistant House Surgeon. Salary £30 per annum, with board, lodging, and washing.

Stockport Infirmary.—Assistant House and Visiting Surgeon. Salary £70 per annum, with board, washing, and residence.

St. John's Wood and Portland Town Provident Dispensary, N.W.—Third Medical Officer. Applications to the Secretary, 1, Henstridge Villas, St. John's Wood.

St. Mary's Hospital, Paddington, W.—Surgeon for Diseases of the Ear for five years.

Swansea General and Eye Hospital.—House Physician for one year. Salary £50 per annum, with board, apartments, washing, and attendance.

Tottenham Hospital.—Resident Medical Officer for one year. Salary £60 per annum, with board, lodging, and washing.

University of Edinburgh.—Professor of Physiology.

West London Hospital, Hammersmith-road, W.—House Physician and House Surgeon for six months.

West Riding Asylum, Menston, near Leeds.—Fourth Assistant Medical Officer. Salary to commence at £100, rising £10 annually to £150, with board and apartments.

Births, Marriages, and Deaths.

BIRTHS.

Anderson.—On March 1st, at East-street, Faversham, the wife of Charles Macdonell Anderson, M.D., M.R.C.S., of a daughter.

Patch.—On March 5th, at the Fernery, Chudleigh, South Devon, the wife of H. H. Lloyd Patch, M.R.C.S., L.R.C.P. Lond., L.S.A. Lond., of a son.

Shaw-Mackenzie.—On March 4th, at 31, Grosvenor-street, W., the wife of John A. Shaw-Mackenzie, M.D. Lond., of a son and daughter.

MARRIAGES.

Papillon—Paton.—On Feb. 14th, at St. Margaret's Church, Westminster, by the Rev. W. L. Paige Cox, Vicar of Rockferry and Rural Dean of Birkenhead, assisted by the Rev. Lennox Tindall, Vicar of Ore, Hastings, brother-in-law of the bridegroom, Godfrey Keppel Papillon, of the Manor House, Kingscliffe, Northamptonshire, son of Philip O. Papillon, J.P. and L.D., of Crowhurst Park, Sussex, and Lexden Manor, Essex, to Jessie Winifred, only daughter of J. Wilson Paton, M.D., Rockferry, Cheshire.

Pedley—Wolsey.—On March 1st, at Denmark-place Baptist Chapel, Samuel Edward Pedley, L.R.C.P. Lond., M.R.C.S., L.D.S., of Camberwell, to Ada Elizabeth, daughter of James Wolsey, of Shelford Lodge, Camberwell.

DEATHS.

Burns.—On March 5th, at his father's residence, Berar, Vale-road, Ramsgate, Alfred Hugh Burns, L.R.C.P.I., L.S.A., aged 44 years.

Gartley.—On March 4th, suddenly, at Sackville-street, Piccadilly, W., John Alexander Gartley, L.D.S.R.C.S. Eng., aged 63 years.

Rodgers.—On Feb. 21st, at Ross, suddenly, Marshall Prime Rodgers, L.R.C.P., L.R.C.S., youngest son of the late J. M. P. Rodgers of Queniborough Lodge, Leicester. Deeply regretted. Interred at Ross, Feb. 25th.

Rose.—On March 7th, at Dale Bank, Chesterfield, suddenly, John Rose, M.D. (Retired List R.N.), aged 76.

Smith.—On March 1st, at Stuart Lodge, Polwarth-terrace, Edinburgh, John Stuart Smith, M.D., retired Surgeon-Major, Army Medical Department, aged 84 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (13th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (9.30 A.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.), London Throat (2 P.M.).

TUESDAY (14th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.).

WEDNESDAY (15th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.).

THURSDAY (16th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.).

FRIDAY (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.).

SATURDAY (18th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (13th).—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. J. Langton: Radical Operation for Inguinal Hernia—and afterwards.

TUESDAY (14th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Papers:—Dr. T. R. Bradshaw and Dr. W. B. Warrington: The Morbid Anatomy and Pathology of Dr. Bradshaw's Case of Myelopathic Albumosuria.—Mr. G. H. Makins: On Prevesical Hernia with the Relation of a Case in which Subacute Strangulation occurred.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (17, Bloomsbury-square, W.C.).—8 P.M. Prof. J. R. Green: Adverse Conditions and their Remedies in the Life of Plants.

WEDNESDAY (15th).—ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Mr. L. Wright: The Projection Microscope.

NORTH-WEST LONDON CLINICAL SOCIETY (North-West London Hospital).—8.30 P.M. Annual General Meeting. Election of Officers. Demonstration of Cases.

ROYAL METEOROLOGICAL SOCIETY (Institution of Civil Engineers, Gt. George-street, Westminster, S.W.).—7.30 P.M. Ordinary Meeting. Papers:—Mr. J. Brodie: The Prolonged Deficiency of Rain in 1897 and 1898.—Rev. H. W. Yorke: The Climate of Jersey.

THURSDAY (16th).—HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne-street, Edgware-road).—8.30 P.M. Dr. Mouillot: Modern Views on Gout in Relation to Treatment.

ROYAL SOCIETY.—Prof. Burdon Sanderson: The Electrical Concomitants of Motion in Plants and Animals (Croonian Lecture).

FRIDAY (17th).—EPIDEMIOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8.30 P.M. Paper:—Dr. W. H. Crosse: Blackwater or Hæmoglobinuric Fever.

SOCIETY OF ANÆSTHETISTS (20, Hanover-square, W.).—Papers by Mr. H. B. Gardner and Mr. A. Granville. Casual Communications.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (13th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. C. Stewart: Alternation of Generation and Recent Additions to the Museum.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. G. L. Cheatle: The Treatment of Wounds and their Complications.

TUESDAY (14th).—ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. G. R. Murray: The Pathology of the Thyroid Gland (Goulstonian Lecture).

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck-street, W.).—4 P.M. Mr. H. W. Dodd: Cases of Visual Disorder in relation to Diseases of the Nervous System.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. Taylor: Syphilitic Diseases of the Nervous System.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. E. Ray Lankester: The Morphology of the Mollusca.

WEDNESDAY (15th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. C. Stewart: Alternation of Generation and Recent Additions to the Museum.

EVELINA HOSPITAL (Southwark bridge-road, S.E.).—4.30 P.M. Mr. S. Stephenson: Clinical Demonstration on Ophthalmic Cases from the Wards (Post Graduate Course).

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Bliss: Chronic Pneumonia.

THURSDAY (16th).—ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. S. Gee: The Causes and Forms of Bronchitis (Lumleian Lecture).

CHARING-CROSS HOSPITAL.—4 P.M. Dr. W. Hunter: Pathological Demonstration (Post-Graduate Class).

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Still: Demonstration of Selected Cases.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square, W.C.).—4.30 P.M. Dr. M. Dockrell: Cases of Purpura and other Hæmorrhagic Affections.

LONDON TEMPERANCE HOSPITAL.—2 P.M. Dr. S. Fenwick: Clinical and Pathological Demonstration to Senior Students.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. G. L. Cheatle: The Treatment of Wounds and their Complications.

FRIDAY (17th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. C. Stewart: Alternation of Generation and Recent Additions to the Museum.

ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Prof. F. Gotch: The Electric Fish of the Nile.

SATURDAY (18th).—ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Right Hon. Lord Rayleigh: The Mechanical Properties of Bodies.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1898, which was completed with the issue of Dec. 31st, and the Title-page to the Volume, were given in THE LANCET of Jan. 7th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1898 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 6*d.*

To be obtained on application to the Manager, [illegible]ied by remittance.

"THE JUST POSITION OF BACTERIOLOGY."

UNDER this heading a letter has appeared in some London and many provincial papers, which letter is signed Maurice L. Johnson and contains a complete misrepresentation of THE LANCET. As a rule we do not pay any attention to these misrepresentations, but when we have reason to believe that no error is being made but that our words have been twisted with the wilful intent to prejudice the medical profession in the eyes of the public we do not always remain silent. Mr. Maurice L. Johnson, in his communication to the lay press, quotes from an article written by the late Dr. C. Egerton Fitz-Gerald of Folkestone which was published in our issue of Feb. 4th and which contains some passages reflecting upon the undue importance—in the writer's opinion—that is now attached to bacteriology. In the course of this article Dr. Fitz-Gerald had occasion to quote from Professor Virchow's address delivered under circumstances that will be fresh in the minds of many of our readers at the opening of the last winter session of the Charing-cross Medical School. Professor Virchow in this address said that every contagious disease must not yet be attributed to a micro-organism, and Dr. Fitz-Gerald, the purport of whose little article was to enlarge upon this text, alludes to Professor Virchow in the following terms: "It will be admitted that men of his eminence, age, and scientific attainments are far better able to calmly review and dispassionately judge of the value of new discoveries and researches than the pure scientist who, with some self-complacency, may choose to dub such views 'old-fashioned.'"

Mr. Maurice L. Johnson's letter quotes certain passages in Dr. Fitz-Gerald's article in which the position of bacteriology is slightingly referred to and asks the public to take a similar view upon the authority of THE LANCET. This is accomplished by attributing to the Editors of THE LANCET Dr. Fitz-Gerald's eulogy of Professor Virchow and making the subject of that eulogy Dr. Fitz-Gerald himself. We have the highest respect for the memory of our frequent correspondent the late Dr. C. Egerton Fitz-Gerald and have put that respect on record in our obituary notice, but we made no editorial comment whatever either upon his article or upon his scientific attainments. We have pointed out this fact to Mr. Johnson who writes regretting a "compositor's error." The explanation is unconvincing to us, particularly as the letter appears in the same mendacious form in so many different papers; but whoever made the mistake it is one that we feel should be pointed out in detail and at once or it will become the source of endless misrepresentation. Every faddist who wants to throw a brick at the medical profession, "the pure scientist," or ourselves, will certainly quote our supposed compliance with a belief that the pretensions of bacteriology have become exorbitant as well as our remarkable tribute of praise to Dr. Fitz-Gerald for having exposed those pretensions. We have experience in the methods of certain papers the proprietors of which have made abuse of the medical profession a part of their general policy.

THE THERAPEUTICS OF COMFREY.

To the Editors of THE LANCET.

SIRS,—Can any of your readers supply information as to the use of comfrey (root or leaves?) applied externally in the form of a poultice to tumours such as sarcomas which cannot be removed? How it is prepared? and has any benefit, even temporary, been derived? Also information as to the internal administration of chelidonium in similar cases.

I am, Sirs, yours faithfully,

March 6th, 1899. W. S.

ALCOHOL AS A FRIGORIFIC.

THE story goes that in the winter of 1786 Prince Potemkin, the magnificent Prime Minister to the great Empress Catherine of Russia, gave a grand banquet in his spacious palace at St. Petersburg in order to do honour to a saint who in his lifetime had been renowned for his asceticism. The Prince's dinners were celebrated alike for their sumptuousness and the multitude of guests invited, but on the present occasion all the previous efforts of the ambitious Amphitryon were placed in the shade. The tables were spread with the utmost profusion and it is on record that no fewer than 22,000 persons assembled to do justice to the fare. As may be imagined in such a hard-drinking age strong liquors were by no means lacking. Brandy, or more probably vodka, literally overflowed; the symposium gradually deepened into a furious orgie, and before long the entire company became more or less intoxicated. The weather that winter happened to be severer than usual. There was not very much snow, but a black frost had solidified every atom of moisture in the soil whilst to add to the general inclemency an icy north-east wind which cut like a knife was blowing furiously. When the drunken revellers emerged at length into the night air they were almost immediately overcome by the intense cold. All or nearly all were enveloped in furs, sheepskins, or other non-conducting wrappings which under ordinary circumstances would have sufficed to protect them, but owing to the fatal influence of the alcohol which they had imbibed the demon of Frost was able to penetrate their defences and seize upon their "vitals." Stupefied and incapable of directing their unsteady footsteps they wandered vaguely to and fro in a vain endeavour to reach the shelter of their homes; but very soon one after another they stumbled and fell to the ground and of those who thus embraced their mother Earth not one in 20 ever rose again. The number of those who perished is put down 16,000, but although this may be an exaggeration there is goo reason to believe that more than half of the carousers lost their liv on this memorable occasion. Now, whether the sad fate of Princ Potemkin's guests be authentic or not there is a moral in th tale which all who are wont occasionally to indulge in mor spirituous liquors than they are accustomed to would do well to bea in mind. Consumed in moderation alcohol does little or no harm healthy persons, while in many forms of illness it is undoubtedly very valuable medicament, still it cannot be denied that the limits physiological moderation are often exceeded by people who regar themselves as strictly temperate and are so esteemed. Whe alcohol has been ingested in a larger dose than the system can dispo of promptly the surplus becomes a source of danger to the ingesto Instead of acting as a stimulant and heat-producer it tends (wheth by inhibition and paralysis or not it is unnecessary now to inquire) bring about the congestion of internal organs at the expense of th periphery which is thus rendered comparatively bloodless an consequently colder than in the normal state. In this conditio with his blood irregularly distributed, the imbiber of surplu alcohol is peculiarly susceptible to the assaults of cold. It true that after a good dinner in a well-warmed room he may n feel in the least indisposed. On the contrary, when under suc circumstances the bottle has been circulating freely his feelings in a *probability will be distinctly* pleasurable; but no sooner is he expose to a low temperature than at once the sensation of well-being begin to vanish, the rapidity of its disappearance being in direct ratio t the quantity of alcohol which he has failed to assimilate. The it is that what are known as "chills" are so liable to attack th badly-protected organism. To guard against these subtle foes th greatest care is needed on the part of all who after spending the tim at a festival in heated rooms are compelled to face the night air whil returning to their domiciles. Too many wraps can scarcely be worn and if in spite of them a chilly feeling should make itself felt whil *in transitu* a warm drink on arrival at home will be found invaluable The ingredients of this "night-cap" are not of much importance Tea and coffee are suitable for such as can withstand the peculia effects of these beverages, or else cocoa, chocolate, soup, &c., may b taken. Whatever the potion may be the essential point is that i should be piping hot.

TESTIMONIALS TO QUACK REMEDIES.

THE following extract from an advertisement shows very well what chemical analytical record should *not* say:—

> POST'S *C. B. Q.*
>
> THE MOST EFFECTIVE CURE YET DISCOVERED FOR GOUT AN RHEUMATISM.
>
> *Extract from Certificate of Analysis.*
>
> * * * * *
>
> "I consider it to be perfectly harmless in use, effective in action and an admirable specific for the cure of rheumatic gout, sciatica lumbago, neuralgia, &c.
>
> "GRANVILLE H. SHARPE, F.C.S.,
> "Analyst; late Principal of the Liverpool College of Chemistry
> Member of the Society of Chemical Industry, &c., &c."

It would not be expedient, perhaps, to give in THE LANCET an additional notice of the above quack remedy (which occupied tw whole columns in the *Times* of March 6th) but the inquiry migh reasonably be made how a late Principal of the Liverpool Colleg of Chemistry and professional analyst (according to his own showing can have acquired the experience which can entitle him to use th language he does in the latter part of his certificate. Even as regard the preparation being "harmless" he can only define as to what h tried to find and did not find there. Its positive virtues he can kno nothing about. But if he will express a deliberate opinion upo what he knows nothing about, of what value is his statement as what he may be presumed to know?

"GLYCALYMPH."

To the Editors of THE LANCET.

SIRS,—I think it would be very desirable to find a shorter and mor easily pronounced name for glycerinated calf lymph, and I wou propose "glycalymph," which is shorter *by* 11 letters and much easi to say, the *y*, of course, retaining its sound in glycerine. Th descriptive words might be used in full for a few years in the notices vaccinate and in a few other cases, but in *by far* the greater number th word "glycalymph" would be preferable and would satisfy all requir ments.—I am, Sirs, yours faithfully,

J. P. H. BOILEAU, M.A., M.D. *Dub.*,
Late Brigade-Surgeon-Lieutenant-Colonel, Army Medical Staff.

Trowbridge, Wilts, March 6th, 1899.

THE TEETH OF THE ANNAMITES.

IN the *Revue Scientifique* of Feb. 18th M. Paul D'Enjoy gives som account of the method of blackening the teeth practised by th natives of Annam. All travellers, he says, on arriving in th country for the first time are astonished to find that *the teeth of th* natives are of a uniform lustrous black colour, like black enam This unusual condition is not the result of chewing betel, althou delusive statements to that effect are made by *the natives* for th purpose of misleading foreigners. The Annamites *abhor* white tee and have been known to say that a European with a bushy moustac and white teeth eating a piece of meat resembles a hungry cat. The process of blackening the teeth is elaborate and tedious. After being well washed they are rubbed first with powdered coral and then with rice vinegar. In the next place, the operator, using special small brushes, paints their entire surface with a mixture of honey, animal black, and powdered calamine (*tous d'aigle*) ground together. Several successive applications of this kind are made every day and afterwards the person operated on has to keep his mouth open until the material dries. This substance becomes a kind of varnish which forms a protective covering but does not penetrate to the interior layers of the tooth. The natives assert that their remarkable freedom from toothache is due to this practice.

CLUB PRACTICE IN AUSTRALIA.

To the Editors of THE LANCET.

SIRS,—I enclose you a copy of a letter which I received on Feb 20th. It may be of interest to your readers as giving further evidence of the deplorable state of affairs with regard to club practice in Australia. You can make any use you like of it.

I am, Sirs, yours faithfully,
F. DIAS.
Merton-park, S W., Feb. 22nd, 1899

[INCLOSURE.]

Victoria, Australia, Jan 10th, 1899

SIR,—I have read with interest Dr Wunderlich's and your letter on the National Deposit Friendly Society and it seems to me that you have both made out a good case for the society and I would like to become more acquainted with its working, &c. In order that I may be able to use this knowledge for a proposed conference between the friendly societies and ourselves. Personally, I have had considerable difficulty here in inducing the lodge I hold to agree to a wage limit That such was necessary you may judge when I tell you I have had on my list a member worth £33,000, and at present I have several worth from £8000 to £500 a year, exclusive of the bank manager, &c. By agreeing to take these (who were already on my predecessor's list) the lodge has given me power verbally to reject any other members, although, as they were careful to point out, their constitution (M.U.I O F.) does not permit them to reject any applicant on the score of wealth, hence their inability to give me a written agreement to do so. I get 20s. for attendance and medicine per member (which includes wife and family up to 16 years) per annum. I get no pay for fractures or minor operations except uterine, I am infinitely better paid than many men who get only 12s 6d per member per annum in the larger towns here. It is the abuse of the lodge system by the wealthy here (Australasia) which renders medical practice so hard and unremunerative. We are endeavouring to alter matters and have held an inter-colonial conference of medicos to consider the situation at which a wage limit of £200 a year was fixed upon Our next move is to have a conference between the friendly societies and ourselves in about three months time. Meanwhile we are endeavouring to form ourselves into a united body and to collect all information on friendly society matters, and it is for this reason I write to you, as the National Deposit Friendly Society seems to have conceded much that we are here seeking for.

Thanking you in anticipation and hoping I am not trespassing unduly on your time.

I remain, yours sincerely,
(Signed) ———.

JESSE FOOT, SURGEON.

To the Editors of THE LANCET.

SIRS,—Can you inform me if Jesse Foot, Surgeon, was connected with the Lock Hospital, London? I have a copy of his treatise on the Lues Venerea—lectures delivered according to the title-page in 1790 and 1791 in Dean-street, Soho, and published in 1792. I bought it a few days ago at a second hand bookshop in Colchester.

I am, Sirs, yours faithfully,
WM. H. HEWLETT, M.D Aberd.
Wivenhoe, Essex, March 8th, 1899.

⁂ Jesse Foot was a well known authority on his subject but does not appear to have been on the staff of the Lock Hospital (see the "National Dictionary of Biography").—ED. L.

"DOES ASPIRATION OF AIR THROUGH CHLOROFORM RENDER IT INERT AS AN ANÆSTHETIC?"

To the Editors of THE LANCET

SIRS,—Having seen a communication with the above heading in THE LANCET of Feb. 11th, in which Mr. A. Alison Bradburne asks if anyone has had a similar experience to his own with the chloroform that has been used in Krohne's modification of Junker's inhaler, I beg to say that my own experience to a certain extent agrees with his and that along with other members of the staff of the Keighley Hospital who have also failed to induce satisfactory anæsthesia with chloroform that had been previously used in the apparatus I now use a fresh supply of chloroform for *each administration* Having only tried this apparatus for a few months I *do not* feel able to speak very positively of its merits but I certainly think that by its use the chloroform is more quickly taken than by the open method and one learns to feel more secure against mishap in the knowledge that at no time is the patient getting more than a safe percentage of chloroform vapour.

I am, Sirs, yours faithfully,
JOHN D BERRY.
Keighley, Feb. 27th, 1899.

"THE NEW LONDON DISPENSATORY."

To the Editors of THE LANCET.

SIRS,—I have picked up an old book entitled, "The New London Dispensatory" by one Salmon, published "from the Red Balls in Salisbury-court, Fleet street, London, March, 1678." It is a bulky tome and apparently complete. Is the work of any value? Perhaps some of your readers may know.

I am, Sirs, yours faithfully,
C. R. WOOD, M B, M.D. Durh.
Frome, March 6th, 1899.

"WHAT IS ADVERTISEMENT?"

To the Editors of THE LANCET.

SIRS,—Many thanks for your kindly receipt of my letter *in re* the supposed interview with me reported in the *Echo*. I need not trouble you further but for the fact that the person mentioned therein as having called on me for "literary purposes" turns out *not* to have been the author of the said "interview" at all. I have just received (naturally to my great surprise) from an intimate personal friend who mainly gained his information from the study of my books the acknowledgment that he wrote all the articles and cast the third into the form of an interview with me, purely on his own initiative, for the purpose of making a more popular article in treating a difficult subject. This he did in utter ignorance that medical etiquette would be thereby infringed He is exceedingly sorry, and, needless to add, so am I; but I feel that I owe to the *Echo* newspaper the publication of this explanation.

I am, Sirs, yours faithfully,
HERBERT SNOW.
Gloucester-place, Portman-square, W., March 8th, 1899.

⁂ We withdraw the unfavourable comments upon the *Echo* which Dr. Snow's previous communication elicited from us.—ED. L.

WANTED A HOME.

To the Editors of THE LANCET.

SIRS,—Can you or any of your readers inform me of any institution where a child with infantile paralysis affecting both extremities would be received? He is intelligent and about four years of age. A small payment could be made.—I am, Sirs, yours faithfully,

J. LIONEL STRETTON.
27, Church-street, Kidderminster, Feb 28th, 1899.

◆

S. S. M. S.—1. Such an advertisement if brought before the notice of the General Medical Council at the time of its appearance might elicit a rebuke from that body. We doubt if the practitioner responsible for it would be struck off the Register. 2. We do not think it at all likely that the Council would punish a practitioner now for an offence committed ten years ago, unless, perhaps, it could be shown that during the whole decade his conduct had been similarly unprofessional. 3. The size of a practitioner's door-plate or notice board stating his professional hours, &c., has never been under the notice of the Council, and we do not think that in this case it would consider the boards as evidence of infamous conduct. 4 and 5. The advertisement published ten years ago was a proper reason for medical men refusing to meet the practitioner in question, but if he has since repented of his wrong-doing some of his professional brethren may hold it right to pardon him 6 and 7. There is no method of reparation open save to live a professional life that is conspicuously free from advertising, but if this has been done for ten years we should be unwilling to counsel great rigour.

S H, S.—Gerrard's Ureometer is one of the best and most convenient (Baird and Tatlock, 14, Cross-street, Hatton-garden) For sugar Johnson's Picro-saccharometer is accurate and reliable (C. E. Muller and Co., 148, High Holborn, W.C.).

P. L.—The point has not been put to us before. The answer will be found against the same initials next week

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received: *Westmorland Gazette, Cornish Times, Peterborough Standard, Norfolk Standard, Rangoon Times, Times of India, Pioneer Mail, The Morning, Hampshire Observer, Scotsman, Builder, Citizen, Architect, Western Morning News, Cheshire Observer, Newcastle Daily Leader, Bradford Observer, Daily Chronicle, Morning Leader, Yorkshire Post, Sheffield Daily Telegraph, Financial News, Scarborough Post, Manchester Guardian, Liverpool Daily Post, Public Health, Bristol Mercury, Brighton Gazette, Leeds Mercury, Sanitary Record, Middlesex Hospital Journal, Watford Leader, Nottingham Daily Guardian, Siam Free Press, North Eastern Daily Gazette, Local Government Chronicle, Mining Journal, Tunbridge Wells Advertiser, Hertfordshire Mercury, Hinckley Free Press, Hinckley Times and Bosworth Herald, Reading Mercury, City Press, Birmingham Argus, Kent and Sussex Courier, Cork Constitution, Citizen (Gloucester), Windsor Chronicle, East Anglian Daily Times, Surrey Advertiser, Local Government Journal, St. Helen's Advertiser, South Africa, Berkshire Chronicle, Clitheroe Advertiser, Bicester Advertiser, Weekly Free Press and Aberdeen Herald, West London Observer, &c.*

Communications, Letters, &c., have been received from—

A.—Dr. Aldersmith, Lond.; Prof. Clifford Allbutt, Cambridge; Mr. W. H. Allingham, Lond.; *Archives Générales de Médecine*, Paris, Editor of; Messrs. Armour and Co., Lond.; Dr. J. C. Armstrong, Treorchy.

B.—Dr. F. L. Benham, Lond.; Dr. J. Brunton, Lond.; Professor Burdon-Sanderson, Oxford; Mr. R. A. Bayliss, Bath; Berkefeld Filter Company, Lond.; Blackburn Infirmary, Secretary of; Bayer Co., Lond.; Breakfast Health Beverage Co., Redditch; Mr. E. Badcock, Lond.; Messrs. Burroughs, Wellcome, and Co., Lond.; T. B. Browne, Ltd., Lond.; Mr. C. Birchall, Liverpool; Birkenhead Borough Hospital, Secretary of.

C.—Mr. W. Coates, Manchester; Dr. Raymond Crawfurd, Lond.; Mr. B. F. Conolly, Lond.; Dr. Wallace Craskery, Eckington; Messrs. J. and A. Churchill, Lond.; Mr. H. F. Cheese, Lond.; Messrs. Crossley, Moir, and Co., Lond.; Messrs. Carnrick and Co., Lond.; Dr. Walter Colquhoun, Glasgow; Mr. A. Chopping, Colchester; Mr. J. Black Cameron, Lond.; Mr. F. W. Clarke, Chorlton-cum-Hardy.

D.—Mr. F. Davidson, Lond.; Mr. N. Davies, Cowbridge; Dr. Clement Dukes, Rugby; Mr. Davis, Lond.; Messrs. W. Dawson and Sons, Lond.

E.—Colonel Engledue, Byfleet.

F.—Messrs. Flynn and Co., Cork; Fromms Extract Co., Lond.; Messrs. H. Francis and Co., Lond.

G.—Mr. Charles Grant, Lond.; General Post Office, Lond., Secretary of; G. T. B.; G. P. E.; Dr. Gee, Lond.

H.—Mr. W. Herbert, Liverpool; Dr. T. Harris, Manchester; Dr. A. R. Hall, Lond.; Mr. H. W. Hunter, Cork; Hovis Bread Flour Co., Macclesfield; Mr. A. Helbig, Lond.; Mr. G. Hermanni, Lond.; Messrs. Hirschfeld Bros., Lond.; Hastings Urban Sanitary Authority; Mr. T. Garrett Horder, Cardiff; Mr. J. Heywood, Manchester; Messrs. Hawkes and Andrew, Williton.

J.—Mr. Raymond Johnson, Lond.; Mr. Robert Jones, Liverpool; Mr. T. R. Jesson, Leeds.

K.—Dr. Robert Kirk, Glasgow; Mr. B. Kuhn, Lond.; Messrs. R. A. Knight and Co., Lond.; K. H. A.; Mr. W. W. Keen, Philadelphia.

L.—Mr. E. W. Lamb, Crewkerne; Mr. H. K. Lewis, Lond.; Mr. C. J. Lownds, Lond.; Mr. C. H. Lee, Spilsby; Mr. Lowndes, Liverpool; Dr. Lee, St. Leonard's-on-Sea; Mr. P. G. Laver, Colchester.

M.—Mr. E. J. Moore, Castle Island; Mr. J. C. Meadowcroft, Lond.; Monmouthshire Asylum, Abergavenny, Clerk of; Mr. R. H. Mills-Roberts, Llanberis; Comte de Marillac, Lond.; Dr. W. Mitchell, Bradford; Dr. W. Mackie, Elgin; Dr. Macintyre, Glasgow; Mr. A. B. MacDowall, Lond.; Mr. L. Macfarlan, Newbiggin-by-the-Sea; Mr. J. Milne, Lond.; Mr. H. C. Marr, Lenzie; M. E. G.; Dr. F. Milward, Birmingham; Mr. Christopher Martin, Birmingham; Mr. T. Meredith, Coventry.

N.—Mr. N. H. Nixon, Lond.

O.—*Ormskirk Advertiser*, Editor of; *Orcadian*, Editor of.

P.—Mr. J. Pennington, Lond.; Mr. A. Phillips, Manchester; Messrs. Potter and Clarke, Lond.; Protene Co., Lond.; Messrs. Parke, Davis, and Co., Lond.; Proprietress, Lond.; Dr. Porter, Stockport; Mr. Y. J. Pentland, Edinburgh; Mr. J. B. Pike, *Loughborough*.

R.—Dr. J. Ryan, Finea; Royal College of Physicians of Ireland, Secretary of; Royal South Hants Infirmary, Southampton, Secretary of; Dr. H. D. Rolleston, Lond.; Messrs. J. Richardson and Co., Leicester.

S.—Mr. C. J. Symonds, Lond.; Mr. G. Stegmann, Lond.; Sanitary Institute, Lond., Secretary of; Spectacle-makers, Company of, Lond.; Mr. C. C. Skardon, Evershot; Stafford County Asylum, Medical Superintendent of; Messrs. Sparkes, Treherne, and Son, Lond.; Smith's Advertising Agency, Lond.; Sanitas Co., Lond.; Mr. Noble Smith, Lond.; Mr. Lionel Stretton, Kidderminster; Mr. J. Sellers, Lond.; St. John's Wood Provident Dispensary, Secretary of; Dr. Spence, Lichfield; Dr. S.; Messrs. W. H. Smith and Son, Manchester; Dr. Smeeth, Stockport; Dr. H. Scurfield, Sunderland; St. George's Hospital, Dean of; Messrs. Street and Co., Lond.; Messrs. A. F. Sharp and Co., Glasgow.

T.—Dr. J. C. Thresh, Chelmsford; Tasmanian Eucalyptus Oil Co., Lond.; Dr. J. C. Thomas, Port Melbourne; Tuborg Lager Beer Agency, Newcastle-on-Tyne; Dr. Turck, Chicago; Messrs. J. Turner and Co., Queensferry.

U.—University of Durham, College of Medicine, Newcastle-on-Tyne; Universal Food and Cookery Association; Union Assurance Society, Lond., Secretary of.

V.—Mr. J. W. Vickers, Lond.; Mrs. L. Veale, Harrogate.

W.—Mr. G. Wardle, Richmond; Miss Woodward, Folkestone; Mr. G. A. Wright, Manchester; Dr. A. L. Whitehead, Leeds; Dr. S. West, Lond.; Dr. Washbourn, Lond.; W. H. P.; Mr. M. Walsh, New Ross; West Riding Asylum, Clerk of.

X.—X-Ray.

Z.—Dr. Zavitzianor, Pera.

Letters, each with enclosure, are also acknowledged from—

A.—Mr. F. C. Angear, Chatham; Mr. W. F. Abbott, Addlestone; Mr. F. C. Allen, Ashton-under-Lyne; Apollinaris Co., Lond.; A. W.; A. S.; A. L.; Messrs. Allen and Hanburys, Lond.; Dr. R. Allison, Liverpool.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

The Lumleian Lectures

ON

BRONCHITIS, PULMONARY EMPHYSEMA, AND ASTHMA.

Delivered before the Royal College of Physicians of London

By SAMUEL GEE, M.D. Lond.,
FELLOW OF THE COLLEGE AND PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

LECTURE I.[1]

Delivered on March 9th, 1899

On the Causes and Forms of Bronchitis.

Mr. President and Gentlemen,—The Royal College of Physicians of London has never forgotten the exhortation addressed by Harvey "to the Fellows and Members of the said College *to search and study* out the secrets of nature by way of experiment." No doubt he used the word "experiment" in a wider sense than that which it bears at the present day, for in his time the terms "experiment" and "experience," originally *synonymous*, had not yet acquired the sharply distinguished meanings which we give to the words. My predecessors in this lectureship have usually drawn the material wherewith they have fulfilled their duty from their experience in the detection and treatment of disease, and the conditions of my life for many years past have put the necessity upon me of following in the same track to the best of my ability. How much more difficult a task this is than to compile lectures out of the unlimited data of that *factitious* experience which we distinguish as experiment is brought home to me when I recall the preparation of the *Goulstonian* Lectures which I gave in this room nearly 30 years ago. Experience cultivates a capricious soil, which too often yields a scanty harvest; the fruits of experience are *those* which nature happens to afford and no more. Our *hopes for the* future lie in the fields of experiment where *we can* work under conditions of our own making and can, as it were, propose questions to nature and compel her to answer them. Results so beneficial to mankind as those afforded by the antiseptic treatment of wounds and by the *serum treatment* of diphtheria make the followers of Hippocrates and Sydenham look with regret upon their methods, so slow when compared with those of experimental pathology.

Definitions.

Scattered through the Hippocratic treatises are frequent references to a doctrine that the brain resembles *a gland and* is the "metropolis" for separation or secretion (words which have almost the same meaning) of cold and viscid humours. When these humours have accumulated in excessive quantity the brain purges itself by discharging them upon the lower parts of the body—a process called catarrh, defluxion, or distillation of rheum, pituita, or phlegm. In the name of the pituitary body we find a survival of this doctrine. The diseases which result from defluxion of rheum have, says Plato, "many names, because the places subject *to the flux* are manifold." By the Hippocratic writers seven kinds of catarrh are enumerated; by the time of Celsus the number had been reduced to three. In the Salernitan verses these same three defluxions are enumerated, but the name catarrh is restricted to defluxion upon the lungs, catarrhus ad pulmones, pulmonary catarrh.

The change from ancient to modern doctrine is marked by a voluminous treatise in six volumes quarto, published between 1660 and 1664, and written by Schneider whose name has been given to the Schneiderian membrane. We must admire the divine leisure of the times which could allow any man to write such a book or any man to read it. This change in the doctrine of catarrh was brought about partly by the progress of anatomy and partly by Harvey's discovery which sapped the authority of the ancients.

Since Schneider's time catarrh has denoted excessive secretion of more or less altered mucus from a mucous membrane. Hence pulmonary catarrh signifies a disordered function of the pulmonary mucous membrane, the result being an excessive secretion. The corresponding lesion of structure—that is to say, inflammatory changes in the mucous membrane—is called "bronchitis," a word which was invented in 1814 by Dr. Charles Badham, a Fellow of this College, and which has to a great extent superseded the old phrase of "pulmonary catarrh." It is amusing to contrast the diminutive duodecimo of Badham with the gigantic work of Schneider. The use of the word "bronchitis" marks the predominant influence of morbid anatomy. Bronchitis and pulmonary catarrh although for the most part they denominate different aspects of the same disease yet do not exactly tally; bronchitis is not always catarrhal; for instance, it may be attended not by flux of mucus but by formation of false membrane.

Causes.

Bronchitis is a disease of much interest for the English people inasmuch as in our country a pulmonary catarrh is the commonest of disorders at all ages and in all ranks and conditions of life. In speaking thus of the frequency of bronchitis it is worthy of note that this opinion is derived from clinical experience and that bronchitis is not a condition which attracts much attention on the post-mortem table, where the severe forms only of the disease are recognised, or, indeed, one might almost say, can be recognised, without much more minute examination of the bronchial tubes than they usually receive. When we ask why bronchitis should be so common we are led to consider the causes of the malady. Let us begin with the simplest case possible and seemingly the most intelligible.

A number of men are working in a room when a large carboy of fuming nitric acid is broken. They all flee. After a time a healthy young man, having tied a wet towel round his mouth, goes back into the room and opens the windows. Symptoms of bronchitis immediately appear, painful soreness down the sternum and dyspnœa, his voice remaining natural. Next day he has a harsh dry cough and abundant small mucous râles all over both lungs; his temperature rises to 101·4° F., his pulse to 100, and his respirations to 56 in the minute. On the third day the temperature varies between 99° and 101°, the respirations fall to 44; the signs in the chest are much the same. On the fourth day the temperature falls from 100° in the morning to the normal in the afternoon; the râles have almost disappeared. On the sixth day he is quite well.

Bronchitis, being an inflammation, presumes irritation of the mucous membrane and in this case there was no reason for supposing that the irritation was originally due to anything besides the nitrous fumes, even if we admit the possibility that microbes might afterwards come to play their part upon a soil thus prepared for them. But the cause of bronchitis is seldom so simple as this.

Breathing dust has long been recognised as a cause of pulmonary catarrh: for instance, Ramazzini two centuries ago devoted several chapters of his book "De morbis artificum" to the diseases, chiefly pulmonary, which attend dusty trades. At the outset it seems to be necessary to distinguish between dust which is alive and inanimate dust. Taking inanimate dust first as being the less complex topic we must again distinguish between dust which contains soluble constituents and that which does not.

Insoluble dust is in most cases of mineral nature, yet the air of a cotton mill is smoky with vegetable dust. The bronchitis resulting from dusty trades is very chronic, insidious in onset and slow in progress. Insoluble dust is supposed to act as a merely mechanical irritant to the bronchial membranes, but can we say that any sort of dust is absolutely insoluble? And when we endeavour to look more deeply into the matter other doubts arise, as usual. We suspect that the tendency to bronchitis which prevails among workmen in dusty trades is often aggravated by intemperate habits in respect of alcohol and tobacco. Probably in some workmen there is an original disposition to suffer in this way, such as we see in many asthmatics who are very sensitive to dust. Moreover, the dust of unclean and ill-ventilated rooms will be very likely to contain morbific microbes and the irritation of the air-passages set up by inanimate dust will favour the operations of the many bacteria which are potent to cause bronchitis. It obviously would be very improbable that these microbes should swarm in impure air and should not be found in the upper air-passages of man. And thus, as a matter of fact, our mouths, becoming active and virulent, when, to quote the Virgilian phrase of which Sydenham was so fond, *qua data porta ruunt*.

Although it is probable that inanimate dust is sometimes noxious by reason of its soluble constituents yet it is not easy to point to many instances of this kind. The dust of ipecacuanha, which is often referred to, produces asthma rather than catarrh, but it may be that this is a distinction without real difference.

The topic of living animated dust follows in natural order. The best instance of this kind of dust is afforded by the pollen of grass which seems to have been proved capable of causing hay fever in some susceptible persons, though that in which the irritant power of pollen inheres is not known. And the question is complicated by the fact that in a few persons the mere odour of roses and some other flowers seems enough to provoke catarrh. although, since the famous experiment of Dr. J. Noland Mackenzie, with an artificial rose, we have learned how large a part in the production of such a catarrh can be played by the power of imagination. Moreover, the particles which convey the smell of flowers must be far too minute to be rightly called dust and therefore we will not pursue the subject here, but only remark that hay fever affords the best evidence of that idiosyncrasy which predisposes to catarrh.

The catarrh which is caused by the living dust thrown off by certain moulds and fungi is sometimes a much more serious affair. The best known of these fungi is the dry rot of deal wood—merulius lacrimans. The disease it sets up is sometimes fatal. Beside the catarrhal symptoms indicated by the epithet "lacrimans" there are signs of poisoning of the whole body. The fungus grows upon the mouth and fauces, whence we may assume that the morbific agent consists of living seeds which under favourable conditions will strike root in the human body, will increase and multiply, will become, in fact, true parasites, and will poison us with their secretions.

Grass pollen is morbific, dry rot is morbific and parasitic, but they are only *accidentally* so; it is not the purpose of their life to cause disease in man. But there are certain living particles called "microbes" which are *essentially* morbific and parasitic, which to the best of our knowledge are that and nothing else, which continue to exist by causing disease and for that sole purpose, as it seems to us—which are morbific or nothing at all because, being merely parasitic in animals, it follows that if these animals ceased to exist the microbes also would become extinct. Some of these microbes are found almost everywhere; they pursue the steps of men and are apt to attack us at all times and places. But some microbes thrive only under certain circumstances; the best known of these causes of bronchitis are typhoid fever and influenza. In some forms of bronchitis the disease is local and expends itself upon the mucous membrane; the catarrh is protopathic. But in typhoid fever and influenza the case is different, the catarrh is deuteropathic and secondary to infection of the whole system. These two diseases are members of the great class of specific fevers and we are compelled by analogical reasoning to believe that other members of that class which are still more powerful causes of bronchitis are also microbic in nature—for example, measles and whooping-cough. How they cause bronchitis is a question not yet ripe for answer, meanwhile we assume that some irritant is conveyed to the mucous membrane by the blood.

We have now passed from the simplest to the most complex causes of bronchitis so far as our knowledge will allow and yet by far the greater number of actual cases of bronchial catarrh remain unexplained. What is the explanation of a common cold? We can hardly doubt that chill by exposure of the body has often something to do with it, but how? Let us note that colds are seldom caught, as we say, in pure air—at sea, for instance—no matter how great the exposure. Let us note also that common colds are often contagious with an incubation period of about three days. You will remember the deeply interesting experience of the St. Kilda cold, a fact which seems to be well proven notwithstanding the incredulity of Dr. Samuel Johnson and which seems to show that persons who are not themselves suffering from catarrh may yet convey the disease to others, and that a cold past and gone confers temporary immunity. We have heard of late that upon some of the small islands in Torres Strait the natives until they took to wear clothes were exempt from coughs and colds. But it is difficult to understand how the mere fact of clothing pure and simple can have been the cause of those disorders. It would seem to be more probable that the inhabitants have been infected by their clothes or other means and that the catarrhs have been really due to the intruding foreigner who brought along with him his civilisation and his diseases.

THE CATARRH.

Of the signs which make bronchitis manifest in the living body the most important is the catarrh, the excessive secretion of mucus. We might expect that physicians would pay great attention to the sputa, and such has been the fact from the earliest times. A sharp distinction has been drawn, since Hippocrates at least, between transparent sputa and opaque sputa; chiefly for prognostic reasons based upon the old doctrine of the concoction of humours, opacity being the sign of maturity and a stage which the secretion must pass through before the catarrh can end in recovery. This distinction being of such prime importance in the opinion of ancient physicians, it is remarkable that they had no words in use to correspond with their ideas. "Phlegma," "blenna," "pituita," "mucus," all these words were used haphazard to signify matter constituting the sputa, whether transparent or opaque. In truth, the distinction is not of great value; however true it may be of acute coryzal secretions that the mucous discharge becomes muco-purulent on the way to recovery we do not always mark these stages in bronchitis even when acute, while in chronic bronchitis the distinction is of small importance, either prognostic or diagnostic. How common it is to see mucous and purulent sputa in the same spitting-pot; to see purulent sputa floating or lying in thin, transparent, colourless mucus: probably the different secretions come from different parts of the bronchial tract. How common it is to observe that sputa expectorated at different times of the day are different in character, the secretion being, for example, nearly pure mucous throughout the day, but much more purulent the first thing in the morning after sleep.

PITUITOUS CATARRH.

To the general rule that the distinction between crude and concocted sputa is unimportant there is one exception worthy of special note. Laennec, in his chapter upon pulmonary catarrh, has much to say concerning a form of catarrh which he calls "pituitous." He uses the word "pituita" in a sense of his own; he makes it signify colourless, transparent, stringy sputum, frothy at the top, and which when the froth has been removed resembles water stirred up with white of egg. We must all recognise the truthfulness of this description. Louis compared the sputum to gum-water, Borsieri to soapsuds. It is to be wished that the word "pituita" be used to denote this kind of sputum only, because there is no doubt that the catarrh which Laennec calls pituitous does present peculiar characters.

He remarks that pituitous catarrh is symptomatic of other pulmonary diseases besides mere bronchitis, especially œdema of the lungs and miliary tuberculosis. With respect to œdema of the lungs let us note that the albuminous or serous expectoration which occasionally ensues upon paracentesis for pleural effusion, and which depends upon acute œdema of the lungs, and which always brings danger and often death, has to the eye all the characters of pituitous flux. Testing the sputa can alone distinguish the two: serous expectoration is highly albuminous; pituita is not albuminous at all. With respect to tubercle let us note that not only miliary tuberculosis but also massive grey tuberculous infiltration may be attended by pituitous expectoration. A man, 35 years old, had a shivering fit on Sept. 6th. On the 8th he felt sudden pain in the right side of his chest, he coughed, and was feverish. On the 16th he was admitted to the hospital, being the eleventh day of his disease. Consolidation of the upper part of the left lung was found, and the previous symptoms having been those which most usually attend pneumonia it was thought that the lung was hepatised. But the consolidation did not clear up as was expected; on the contrary, the physical signs of disease increased, and by Oct. 10th (the end of the fifth week of illness) the breathing about the left nipple was cavernous. All this time the sputa were pituitous, a fact which seemed contrary to the notion of ulcerating tubercle; moreover, the expectoration was examined twice for tubercle bacilli, probably with insufficient care, and I am speaking of a time seven or eight years ago when there was less skill in this method of examination than at present; but, at any rate, tubercle bacilli were not found. Soon afterwards the pituitous sputum became mingled with muco-purulent masses; the physical signs were much more extensive; finally all the expectoration was muco-purulent and nummular and the man died on Dec. 25th after an illness of between three and four months. Post mortem the left lung was found to be solid with grey tubercle from apex to base; there were only two cavities and these of small size.

Besides pulmonary œdema and tubercle there are two other diseases of the lung which are often attended by pituitous expectoration—namely, the congestion which is consequent upon a dilated heart and contracting cancer.

Pituitous catarrh is sometimes "idiopathic"—a word which we need not be afraid to use provided we attach a definite meaning to it. The original and etymological meaning of the word is its true meaning and pituitous catarrh is idiopathic when it constitutes the whole of the disease. It is sometimes acute, sometimes chronic, and in either case is a very serious condition. The acute catarrh occurs at all ages and often in persons perfectly healthy who have shown no previous tendency to pulmonary disease. The secretion rapidly becomes so profuse that it puts life in jeopardy and will sometimes even kill by suffocation in a day or two. Yet for the first few hours the attack resembles a common cold with cough, and there are no peculiar symptoms attending the earliest stage which enable us to foresee that we have to do with the beginning of so formidable a disease. It does not always kill; sometimes it runs the course of ordinary severe bronchitis and ends in recovery.

Chronic pituitous catarrh is more common. It is serious on account of its obstinacy. To Laennec's admirable description of this disease there is nothing to add unless it be to say that it does sometimes attack persons in the prime of life. A Japanese, 25 years old, came over as a ship's steward to England and immediately upon his arrival began to suffer from shortness of breath and cough—a new thing for him. After these symptoms had lasted for 14 weeks he was admitted to the hospital. There were much dyspnœa and most abundant expectoration of pituita. Tubercle bacilli were not found. The physical signs were those of severe bronchitis. For days together he seemed about to die from suffocation, but under very careful treatment he improved until, without any obvious cause, the symptoms recurred in full severity. Another improvement was followed by another relapse and more than four months had passed away since his admission ere he could be discharged fairly convalescent. This was on May 8th; but on June 16th he was readmitted with all his former symptoms; he went out on July 16th. On Dec. 5th he was admitted once more and the time of the year was probably the reason why we could not get rid of him till Feb. 25th. He had now been a patient on and off for more than a year and as there seemed no end to this sort of thing the sister of the ward got up a small subscription and shipped him off to the antipodes

PECULIAR KIND OF BRONCHITIS.

There is a form of disease which may justly claim to be called catarrhal if we use that word in its strict etymological sense. Graves, speaking of the condition referred to, says: "When an old person reduced by some previous disease catches cold and gets in consequence a sudden and remarkable hoarseness so that he can only speak in whispers; when in addition to this he has cough, stridulous breathing, and copious muco-purulent expectoration, you may be sure that the case is a bad one and the patient in most imminent danger." He goes on to say that the disease is accompanied by considerable fever and that he did not recollect that he had ever seen an attack of this kind that did not terminate fatally. He narrates the case of an eminent country practitioner who "had got an attack of cold followed by hoarseness, which went on for two or three days without being attended to, until one evening he suddenly became alarmingly ill. He was found to be labouring under hoarse breathing, constant laryngeal cough, prostration of strength, and enormous muco-purulent expectoration. His pulse was very rapid, he complained much of oppression of the chest, and he died on the following night, more with symptoms of exhaustion than of asphyxia." Graves tells of another similar case in which the "breath became exceedingly fetid. The expectoration also exhibited a very remarkable change; it was greenish, ichorous, and had a most intolerable fœtor. He now began to manifest symptoms of awful prostration; his distress of respiration became intense, his eyes fixed, his extremities cold, and he expired in about 40 hours from the commencement of the attack."

But this form of bronchitis sometimes occurs in old people whose health has certainly not been "reduced by some previous disease." I saw a lawyer, 74 years old, with Dr. T. Robinson. He was in good health when one April, while waiting for a train at Wimbledon, he was exposed to a chilling east wind. Next day, April 8th, he lost his voice. On the 9th his breathing became a little affected and swallowing was very painful. His voice was not much more than a whisper. Seen by the laryngoscope the epiglottis was very red but not much swollen; the ary-epiglottic folds were not swollen; the glottis was widely open and through it there welled up much muco-pus. On the 10th he seemed better in all respects. He expectorated much brownish muco-pus which, both in colour and smell, reminded one of the sputum of gangrene; this phlegm came up with the least possible effort, hardly amounting to cough. The laryngoscope showed that the redness of the epiglottis was less and that there was no swelling whatever. The voice was much louder. But during the night he became worse; fever appeared for the first time and he complained of pain in the left side. The laryngeal symptoms were gone and his voice was natural, but his breathing became very frequent and he died at evening on the 11th. The fœtid expectoration calls for remark. Graves assumes that in his case the lung had mortified, but he gives no proof of this, and in my case the fœtor occurred within 48 hours from the beginning of the illness in a man previously healthy. Gangrene would hardly set in so rapidly as this. To suppose, in the absence of post-mortem examinations, that the smell is due to decomposition of the secretions—to a fœtid bronchitis, in short—would seem more probable.

Disease of this kind is not peculiar to the old. Some years ago I saw a boy, aged seven years, with Dr. Bland. The patient had been seized a day or two before with laryngeal symptoms which, when I saw him, deserved the name of croup, and the dyspnœa became so urgent that tracheotomy was demanded and performed. We could see that the epiglottis was not swollen but we could make out nothing more, for examination by the laryngoscope brought on vomiting. The dyspnœa was somewhat relieved but the boy died a few hours after the operation with all the signs of pulmonary dyspnœa. The only part which we were permitted to examine post mortem was the larynx; its mucous membrane was exceedingly red, but there were no false membranes and no œdema, nor were false membranes expectorated or seen during life. The laryngitis was a part (but at first the most obtrusive part) of more widely diffused inflammation. When tracheotomy set the laryngeal symptoms aside the bronchitis became manifest. Moreover, in this case there was no reason for suspecting measles. The analogy of the early laryngitis stridula of that disease will occur to your minds at once.

It is likely that the disease in question is essentially of the same nature as œdema glottidis—that is to say, a specific inflammation spreading rapidly, like erysipelas. Hippocrates uses this very word and in several places speaks of erysipelas in the lung, but to identify the disease thus designated by him is not easy.

DYSPNŒA.

To breathing with conscious effort we give the name of dyspnœa. It arises from a peculiar sensation which is not always of the same kind. Two sensations at least can be distinguished. One is sensation of want of breath and impels to inspiration; another sensation impels to expiration. The feeling of want of breath arises within the chest and seems to involve all the thoracic organs. The feeling which impels to expiration seems to arise from the windpipe—that is to say, a patient suffering from expiratory dyspnœa will refer this feeling to the manubrium sterni and region of the trachea. This tracheal sensation closely resembles the feeling which impels to cough and it is the cause of that expiratory groaning which is so common during the uneasy sleep of patients suffering from bronchitis, emphysema, or heart disease. I do not refer to snoring or stertor, which are inspiratory noises. Thus medical physiology requires two respiratory centres, one for inspiration and one for expiration.

It has been said that in bronchitis attended with laborious breathing the chief difficulty is in inspiration; that the expiratory act, on the contrary, is always accomplished with comparative ease; and that these phenomena of laborious breathing, particularly the long-drawn, exhausting, inadequate inspiration, are probably quite peculiar to obstructive bronchitis. But surely these propositions are far from being universally true. Even in slight bronchitis occurring in a man who never had bronchitis before the expiration may be much more forced than the inspiration in consequence of the provoking tracheal sensation spoken of before. In chronic bronchitis when the patient raises phlegm with difficulty the most obvious thing about the respiratory movements in many cases is the forced expiration. If we would see inspiratory dyspnœa in its highest degree and purity it is not to bronchitis, but to laryngitis, that we must look; to angina laryngea, not angina bronchialis. In mere bronchitis we seldom see anything like the inspiratory dyspnœa of croup.

LIVIDITY.

Lividity is not a marked symptom of bronchitis except in the worst cases. When we see a patient whose dyspnœa amounts to orthopnœa and whose lips are purple or almost black we suspect at first sight disease of the heart rather than disease of the lungs. Again, if we see great lividity in a case of bronchitis we suspect some complication—for instance, pulmonary emphysema, extensive collapse, broncho-pneumonia, scattered tubercle, or distended heart.

The phrase "suffocating catarrh" has been used in senses so varied that some persons have suggested that it should be wholly discarded. Even apoplexy and croup have borne that name. We can continue to use it only on condition that suffocating catarrh shall signify bronchitis in which the patient is in danger of being stifled by bronchial secretion thrown out more rapidly than it can be expectorated. The metaphorical phrase "paralysis of the lungs" has been applied to these cases of catarrhal infarctus. We meet with suffocating bronchitis under three conditions. First, in infants; and a main cause of their liability to suffocating catarrh is to be found in the shape of their thorax which, being almost circular on horizontal section is incapable of more than small lateral expansion. The only extraordinary enlargement which their chest can undergo is by vertical elongation, upwards by means of the accessory inspiratory muscles and downwards by excessive diaphragmatic contraction. Moreover, their ribs are often soft and rickety. Next, we meet with suffocating bronchitis in adults when they are attacked by pituitous catarrh in a severe degree. And, thirdly, suffocating bronchitis is common as an exacerbation of chronic bronchitis in persons who are for the most part advanced in life.

In these cases, post mortem, we often find that form of pneumonia which bears no name adopted universally. Our own Nomenclature gives us the choice of three names. We may use the name "lobular pneumonia," in contradistinction from lobar pneumonia; or "broncho-pneumonia" in contradistinction from pleuro-pneumonia; or catarrhal pneumonia in contradistinction from what has been called "croupous pneumonia." The name of broncho-pneumonia is to be preferred. Croupous pneumonia is what Polonius would have called a very vile phrase. It is amusing to note how the Lowland Scotch word "croup" (the cognate English word is "roup") which signifies a certain kind of noise, has come to be applied to a morbid exudation—a perversion due to foreign pathologists who could not have known the meaning of the word which they were using or abusing. And thus croup, having undergone this strange metamorphosis in the course of his travels abroad, comes back disguised to his native land and we receive him with open arms. Such are English ways.

Broncho-pneumonia is the last stage of inflammation extending downwards along the air-passages into the pulmonary lobules. Catarrh implies a mucous membrane; but the bronchiola which feed the pulmonary lobules with air possess no mucous membrane; in these parts, therefore, lobular hepatisation takes the place of bronchial catarrh. The difference in the products of exudation depends more upon the situation of the disease than upon any difference in its cause. The microbes found in lobular pneumonia are the same as those found in bronchitis although the relative frequency with which they are found is not the same in the two diseases. To the last volume of St. Bartholomew's Hospital reports Dr. Horton-Smith has contributed a valuable paper upon the bacteriology of acute broncho-pneumonia. He finds that the microbe most frequently present is pneumococcus, less frequently streptococcus, and still less frequently staphylococcus. He finds that the broncho-pneumonia of typhoid fever is due to these common microbes and not to the special typhoid bacillus. But he thinks that the broncho-pneumonia of diphtheria and influenza most frequently depends upon their several proper and peculiar microbes; and yet that in a few cases the pneumonia is not specific—that is to say, none but the common pyogenic microbes are found. One very practical truth has been well established—namely, that in measles the frequency with which broncho-pneumonia occurs is dependent upon the degree of impurity in the air breathed. The main cause of death in measles is broncho-pneumonia, and the mortality in some epidemics has been as high as 50 per cent. Thus any mysterious change of type or epidemic constitution seems to be resolved, so far as concerns measles, into the condition of the air breathed by the patients. Hence the necessity for isolation, for ventilation, and for cleanliness.

The pneumonic part of broncho-pneumonia is a post-mortem disease or, in other words, it can seldom be detected with certainty during life. In severe progressive capillary or suffocating bronchitis which threatens the patient with death we may assume that lobular pneumonia is present, inasmuch as it is the last stage of the disease. Neither symptoms nor physical signs help us much; the patient is too ill to bear prolonged examination; nor does it matter in the least whether we detect the pneumonia or not, for our treatment is the same in both cases.

CHRONIC BRONCHITIS.

Chronic bronchitis associated with emphysema, and in all respects like the disease common in old people, is by no means very uncommon in the young—that is to say, in patients under 20 years of age. But this is the case especially among the lower classes of the people; among the well-to-do chronic bronchitis is uncommon in the young. When we bear in mind that with asthma it is quite the reverse—that juvenile asthma is common among the well-to-do and uncommon among the lower classes—the suspicion arises that we have to do with what is essentially the same disease assuming different forms under different conditions of life. The poor are very careless with regard to their health and it is probable that through neglect what would otherwise be asthma becomes a chronic pulmonary catarrh.

The heart is dilated more easily in children than in adults and thus cases of juvenile chronic bronchitis gradually pass into a state wherein the symptoms of dilated heart predominate over those of the original disease. Some years ago I examined the body of a boy, 13 years old, who had suffered from chronic bronchitis since 18 months of age, when he had measles and whooping-cough. He was so deeply cyanotic that the question of malformed heart arose; his fingers were much clubbed and there was universal dropsy. The post-mortem examination showed emphysema of the lungs, especially of their anterior parts. The right side of the heart was much dilated and hypertrophied, but there was no valvular disease nor was there any malformation. The liver was nutmeg.

That predisposition which tends to make bronchitis chronic is often hereditary and is often acquired. In many persons a powerful assistant cause of the chronic bronchitis is alcohol. Sydenham alludes to this fact when speaking of "peri-pneumonia notha," which no doubt for the most part consisted of febrile exacerbations of chronic bronchitis. He says that the disease "affects those who are of virile age, or, what oftener happens, those who are older and who have been too much given to spirituous liquors, especially to brandy." The evil effect of alcohol is sometimes seen in persons who cannot be justly called intemperate and a marked diminution of the tendency to bronchitis will sometimes occur in patients who become total abstainers after having been in the habit of drinking not more than a usual quantity of wine. The swollen, deeply red, and irritated soft palate of many hard drinkers probably affords a clue to the nature of alcoholic bronchitis.

Post-mortem examination of the bodies of persons past middle life reveals the fact that their chronic bronchitis is seldom unassociated with chronic nephritis, arterio-capillary sclerosis, chronic endocarditis or pericarditis or myocarditis, and atheroma of the aorta, not to speak of pulmonary emphysema—lesions which constitute an important part of the condition which we designate "old age."

That a tendency to chronic bronchitis and a tendency to gout concur in many patients is a frequent experience and there can be no objection to our expressing this fact by calling the bronchitis gouty, provided the evidence of gout be sufficient. But I fear that gouty bronchitis is often talked about when the evidence of gout is small. Before the term "gouty" is predicated of any disease the reasons for the affirmation ought to be carefully examined. To define the word "gout" is not possible, the essential nature of gout we do not know. Doubtless there are satisfactory criteria or notes of gout, such as regular attacks in the hand or foot, tophi, and the discovery of uric acid in the blood. But medical men are often content with much lower probability than this when they pronounce a patient to be gouty and I am far from saying that they are wrong. Howbeit the name of "gout" has been extended in meaning so as to include a vast number of diseases, but whether these speculations are as sound as they are ingenious, whether they are solid structures grounded on truth or no more than the phantoms of a lively imagination I will not take upon myself to determine. Time will show. "*Medicina non ingenii humani partus est sed temporis filia.*"

PHTHINOID BRONCHITIS.

There is a form of chronic bronchitis which bears a close resemblance to tuberculous pulmonary consumption; the disease is nothing but bronchitis, yet the symptoms are those of phthisis pulmonalis. The interest of this topic is mainly antiquarian for us because it throws an important light upon the progress of pathology. Before the invention of auscultation the patients alluded to were necessarily believed to be suffering from pulmonary consumption, and, indeed, they were so suffering in the original sense of the phrase. For the epithet, "consumption" or "phthisis," related to the condition of the whole body, to the progressive emaciation in fact, while the word "pulmonary" indicated that the disease, whatever it was which caused the emaciation, was seated in the lungs. This was the sense in which our eminent Fellow, Richard Morton, used the phrase in his admirable book entitled "Phthisiologia." In the phthinoid or consumptive form of bronchitis there is an abundant expectoration of purulent sputa. The early physicians knew of no source of pus but an ulcer and hence they inferred that the lungs were ulcerated. The first man to discover that this was not the case was that singularly accurate observer Antony de Haen; but even after he had shown that the lungs, examined post mortem, were to all appearance sound, free from all ulceration, and yielding not a drop of pus on section, yet matters were not much advanced for practical medicine because the diagnosis could not be made during life. And here the subject stood until the time of Laennec. Perhaps you remember that Sir Thomas Watson confessed in his lectures that he once made this mistake and pronounced a young woman to be in the last stage of consumption who soon afterwards made a rapid and complete recovery, he having omitted to auscultate her chest. Even auscultation does not always enable us to distinguish these cases with perfect certainty, but since Robert Koch's discovery of the *tubercle bacillus* we have a potent auxiliary to diagnosis in the microscopic examination of the sputa.

CONCLUSION.

In conclusion, we will revert to the results of our search into the causes of bronchitis. We found it to be highly probable that most catarrhs are due to a specific infection and they often depend upon contagion spreading from man to man. This doctrine has very important bearings upon medical practice. It leads us to believe that the means by which we may prevent catarrh are to be found in ventilation and cleanliness, if, indeed, ventilation be not a kind of cleanliness. Experience confirms this belief. When epidemic catarrh prevails where do we find most of our patients? In those houses which are obviously the worst ventilated, even though they be the spacious houses of the rich. And where do our patients catch their catarrh? Either in houses of the kind which I have mentioned or in buildings where men most do congregate, especially in offices, shops, and churches. Large shops and stores, public museums and libraries, are ventilated as little as possible for fear of their contents being spoilt by smoke and dust. Many churches both in town and country are never properly aired for another reason—namely, because their architecture does not admit of it. Those "rich windows which exclude the light" do worse than this, they exclude fresh air. The revival of Gothic architecture has been, from the sanitary point of view, a great mistake. Our despised forefathers of the eighteenth century erected plain and simple buildings which could at least be well aired, well-lighted, and kept warm and comfortable; nay, even the much ridiculed churchwarden, with his brush and pail of whitewash, was a praiseworthy minister of health. Modern dwellings are no better than the churches. In the matter of domestic sanitation people have fixed their attention too exclusively upon the drainage and the water supply; light and air are not reckoned. Many of the large red-brick houses which have been built in great numbers at the West end of London and elsewhere during the last 25 years cannot be properly ventilated. The well of the staircase ought in every house to be a reservoir of pure air and to have an independent supply from without. But in many houses the staircase cannot be ventilated except through the rooms, and, in fact, it never is ventilated. Nor are the rooms themselves much better off; their heavily mullioned windows are designed with small regard to the transmission of light and air. The subsidiary and merely ornamental arts which do no more than please the eye are studied to the neglect of that far greater art which promotes the happiness and welfare of the whole man, the Art of Preserving Health.

The Goulstonian Lectures

ON

THE PATHOLOGY OF THE THYROID GLAND.

Delivered before the Royal College of Physicians of London on March 7th, 9th, and 14th, 1899,

BY GEORGE R. MURRAY, M.A., M.D. CANTAB., F.R.C.P. LOND.,

HEATH PROFESSOR OF COMPARATIVE PATHOLOGY IN THE UNIVERSITY OF DURHAM; PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE.

LECTURE III.[1]

Delivered on March 14th, 1899.

COMPENSATORY HYPERTROPHY.

MR. PRESIDENT AND GENTLEMEN,—The whole question of compensation and compensatory hypertrophy of organs in disease is of such great interest and practical importance to us that any facts which tend to throw light on the conditions under which they are developed are of value. In health we can by specially arranged exercises bring into operation the pathological law, that any muscle contracting intermittently against an increased resistance which it can overcome undergoes hypertrophy, and thus induce hypertrophy of the biceps or any other muscle. In some diseases our chief object is to favour and encourage compensating hypertrophy by every means in our power. In valvular disease of the heart adequate compensation in the form of "work hypertrophy" is of prime importance, the object of our treatment being to encourage and maintain its proper development and as long as possible ward off the disastrous effects of its failure. All hollow muscular organs develop compensatory muscular hypertrophy when their work is increased by some abnormal resistance to the expulsion of their contents which can be overcome by an extra effort. Other tissues also can undergo similar changes, an example of which is given by the condition of the blood in cyanosis. It has been shown by Toeniessen, Gibson,[2] and others that in the intense cyanosis of congenital heart disease the hæmoglobin is increased in amount and the red and white corpuscles are increased in number. The hæmoglobin may be increased up to 120 or 160 per cent. of the normal amount, the red corpuscles up to 9,000,000 (about double the normal number), and the white to 16,000 in each cubic millimetre of the blood. These changes may fairly be regarded as indicating a compensating hypertrophy of the blood which enables it to carry more oxygen in face of the adverse conditions under which the circulation is carried on. Marie regards a similar increase in the number of the red corpuscles which occurs in those who live at high altitudes as a similar compensation. The glandular organs of the body have also remarkable powers of development under the influence of appropriate stimuli, as, for example, the development of the mammary glands during pregnancy. Both secretory and excretory glands can undergo compensatory hypertrophy when a portion of the gland has been disabled by disease or design in such a manner as to throw an increased amount of work upon the remainder. The stimulus of working at higher pressure than normal here as in the heart leads to a development of a compensatory hypertrophy, such, for example, as is seen in one kidney after the removal or destruction by disease of the other.

---

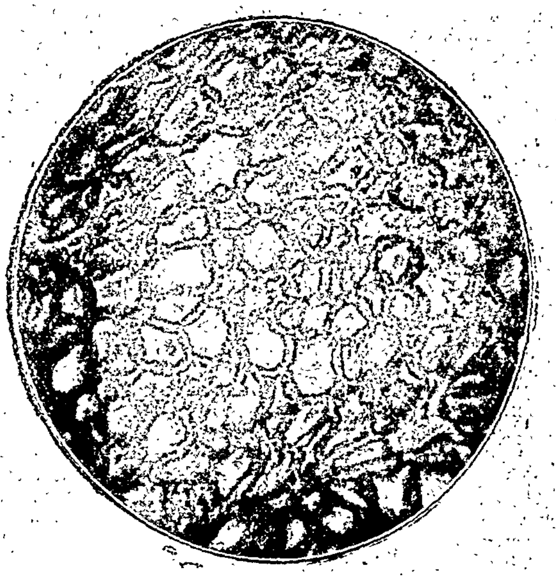
[1] Lectures I. and II. were published in THE LANCET of March 11th, 1899.

[2] THE LANCET, Jan. 5th, 1895.

It is important in all cases to ascertain the minute structure of organs which have thus developed a compensatory hypertrophy for it is not necessarily a simple hyperplasia or exact reproduction of the normal structure. In the kidney Lazarus-Barlow[3] states that there is hyperplasia of the cells and hypertrophy of the glomeruli, and he quotes Eckhart's statement that if the hypertrophy is the result of congenital absence of one kidney there is both hypertrophy and hyperplasia of both glomeruli and tubes; if later in life one kidney is destroyed or removed hypertrophy without hyperplasia of either glomeruli or tubes is found in the other. Owing to the special anatomical position and physiological properties of the thyroid gland it affords unusual facilities for observing some of the phenomena of compensatory hypertrophy. It is now a well-known fact owing to the work of Horsley,[4] Halsted,[5] and Edmunds[6] that when a portion of the gland is removed the remainder undergoes compensatory changes in virtue of which it is enabled to supply enough secretion to prevent the appearance of the symptoms of athyroidism. The portion removed at one time may be one-half or even three-quarters of the whole gland and Halsted has shown in the dog that successive portions, if removed on three or four separate occasions, may be excised until only one-eighth or even one-sixteenth of the original gland is left without symptoms of athyroidism being developed, so great is the power of undergoing compensatory hypertrophy. Although these changes are accompanied by an increase in size the hypertrophied remainder does not attain the size of the original gland, so that weight for weight it has to do more work than the original glandular tissue. Under these circumstances it is not so surprising that the structure of a piece of the gland which has undergone compensatory hypertrophy should differ somewhat from that of the normal gland. And this we find to be the case, for when sufficient hypertrophy has developed to supply as much secretion as is necessary we do not find a simple hyperplasia of the original glandular tissue but considerable change in structure throughout. The alveoli instead of being nearly circular become irregular in outline. This change is due to the folding of the wall which projects at different points into the lumen of the alveolus. In advanced hypertrophy the lumen may appear to be star-shaped or it may be almost obliterated by neighbouring folds of epithelium coming into contact. The appearance in places may then closely resemble that of a racemose gland. The epithelial cells themselves are also altered. They are considerably increased in size, the ordinary low cubical epithelial cells being converted into tall columnar cells. The result of these two changes is that in equal areas the secreting cells are greatly increased both in numbers and size in the hypertrophied as compared with the normal gland. The colloid lying in the gland is diminished in amount and appears to be more watery in consistence than normal. This change in consistence cannot, however, be accompanied by any deficiency in the active ingredients of the secretion as it is able to prevent the onset of any symptoms of athyroidism. The appearances just described are evidently those of glandular tissue working at high pressure and just able to supply the necessary amount of secretion without storing any in reserve in the alveoli as is usual in the normal gland.

In illustration of these changes I may refer to an experiment in which I removed the whole of the left lobe and the greater part of the right from a rhesus monkey. After the operation there was slight hebetude and harshness of the voice. No other symptoms developed although the animal was kept under observation for 14 months and then was killed as it contracted general tuberculosis. A piece of glandular tissue which had developed from the small portion of the right lobe left at the operation was found, weighing 0·42 gramme. Fig. 14 shows the changes in structure which had taken place. The folding of the epithelium giving a larger secreting surface is clearly seen and in some of the smaller alveoli near the centre the consequent irregular shape of the lumen is evident. The epithelial cells have become columnar in type while the colloid is scanty and seems to be watery in consistence.

FIG. 14.



Compensatory hypertrophy of the thyroid gland of a monkey, showing plication of alveolar wall, scanty colloid and columnar epithelium.

The remarkable results which have been shown by Dr. Rose Bradford to follow the excision of a portion of the kidney and which were so well described by him in his Goulstonian Lectures last year raise the question as to whether these changes in the structure of the thyroid are due entirely to the wants of the body acting as a stimulus to the compensatory growth of the gland or whether they are in any way due to some other local or general effect of the operation itself. If the compensating growth of the one lobe takes place simply in response to a call for more secretion to make good the loss of the other lobe no hypertrophy should take place if this want is fully supplied from other sources. This point may be tested by removing one lobe of the gland and giving thyroid secretion continuously for some time and then removing the other lobe for examination. If no changes indicating compensatory hypertrophy are found in the second lobe it goes far to show that the hypertrophy develops simply as the result of an insufficient amount of thyroid secretion being present in the blood. To test this point the right lobe and parathyroid were removed from a male bonnet monkey. For the next three weeks 12 minims of thyroid extract were given in the course of each week. Then as the animal became rather emaciated the quantity was reduced to half this amount for the next five weeks. Slight myxœdematous symptoms then appeared, but they diminished on increasing the dose to 24 minims in the week; this was continued for two and a half weeks when the animal died from dysentery. The left lobe was found to be pale in colour and only weighed 0·03 gramme. No parathyroid was found attached to it. Microscopical sections showed no signs of compensating hypertrophy even in its earliest stages. In another experiment the right lobe and parathyroid were removed and one minim *per diem* of thyroid extract was given by the mouth for 16 weeks and then the left lobe and parathyroid were removed. The right lobe with the parathyroid which was removed first weighed 0·3 gramme and was found to be abnormal in structure to start with, as it resembled a hypertrophied gland in structure.

[4] Brit. Med. Jour., Dec. 5th, 1896.
[5] Johns Hopkins Hospital Reports, 1896.
[6] Journal of Pathology, January, 1893.

Similar appearances were found by Halsted in the thyroid gland of several healthy dogs. The occasional occurrence of such changes in apparently healthy animals is at present difficult to explain. The interesting point in this case is that after the prolonged interval of 16 weeks during which the extract was given the left lobe was found to be paler in colour and it weighed 0 25 gramme. The microscopical structure was normal and showed no signs of commencing compensatory hypertrophy. If this lobe was originally in the same condition as the right the treatment seems to have restored it to a normal condition, and if not it at any rate showed no signs of compensating hypertrophy. As far as they go these experiments tend to show that if the proper amount of secretion is supplied after the removal of one lobe compensating changes do not take place in the other.

In connexion with this part of the subject I have tried the effect of prolonged administration of thyroid extract upon the healthy thyroid gland. It is well known that parenchymatous goitres often decrease in size when treated by thyroid extract. One explanation of this result is that a partial atrophy from disuse is established when the full amount of secretion is supplied from an external source. Two experiments have been made to ascertain if any atrophic changes could be induced in the healthy thyroid gland by supplying secretion ready made, as it were, and so doing away with the normal stimulus to secretion. The thymus atrophies after the first year of life from disuse and the thyroid does so itself in old age possibly for the same reason.

A small bonnet monkey was given one minim of thyroid extract *per diem* by the mouth for 44 days and then three minims for 31 days. The thyroid gland was then removed It looked small and pale in colour and with the two parathyroids weighed 0 11 gramme. The microscopical appearance of the gland was normal, the epithelial cells and their nuclei being stained as usual and the alveoli were well filled with secretion. In another similar experiment a male bonnet monkey was given one minim of thyroid extract for 44 days and three minims daily for 42 days. The thyroid gland was then removed and with the parathyroids weighed 0·14 gramme. The nuclei were all stained and the alveoli were well filled with secretion There was rather more fibrous tissue in the interalveolar spaces than is generally seen in the normal gland, but not a sufficiently well-marked increase to amount to a pathological change. The glands were certainly pale in colour and light in weight and appeared to have undergone some diminution in size, but no evidence of atrophic changes was found in the microscopical specimens. Possibly if larger doses had been given for a longer-period some more definite change in the structure of the gland might have been found.

GOITRE

The pathology of goitre is a subject of much importance for the disease is still endemic in this country in the valleys which drain the Pennine Range of hills east and west from the Border as far south as the Peak in Derbyshire Time will not permit me to discuss the origin of endemic and sporadic goitre, but I wish to draw attention to the interesting effects which have followed the treatment of simple parenchymatous goitre by thyroid extract. At first sight such treatment may seem somewhat superfluous, but experience has shown, and to that of others I can add my own, that this method of treatment frequently leads to a notable diminution in the size of the goitre. Adenomata, cystic adenomata, and other new growths are not influenced by the treatment though the parenchymatous enlargement which often accompanies them may be diminished. In the treatment of goitre it is advisable to begin with 10 minims of liquor thyroidei each night. In the course of a few days if the pulse is not accelerated beyond 90 or 100 this dose may be given twice and at the end of a week thrice daily. If well borne the dose may be still further increased. The treatment should be continued for three or four weeks to give it a fair trial and longer if the goitre continues to decrease in size. In several cases in which the general enlargement of the gland has been sufficient to cause dyspnœa by compressing the trachea, so that an operation had to be considered, the gland has been reduced to two-thirds or even one-half of its former size and all the symptoms of pressure removed and with them the necessity for an operation. The beneficial effects of this treatment may be due to the iodine which is present in combination with a proteid in thyroid extract, for iodine has long been used with good results in the treatment of goitr We have seen that the healthy thyroid of the monkey showe some signs of diminution in size under the same treatme and I would suggest that the decrease in size in goitre may due to part of the enlarged gland passing into a resting co dition and consequent diminution in size if there is not actual disuse atrophy as a result of the treatment.

EXOPHTHALMIC GOITRE.

Exophthalmic goitre, with its many varying phases, is disease of great interest from several points of view. Th various clinical types in which it comes before us ar the great difficulties in treatment which it often presen render a true solution of the problem of its patholog of the greatest importance. The circulatory and nervou systems have each in turn been considered to be fault, and it is only recently that attention has bee drawn to the important part which is played by th thyroid gland in the pathology of the disease. Th central and sympathetic nervous systems have been carefull examined in a considerable number of cases; in some the have been found quite normal, in others various lesions hav been described, but these have varied in different cases an on the whole appear to be rather secondary than primary i origin. I shall not describe the various lesions which hav been found, as I have already elsewhere[7] discussed thei relative importance. The lesions found in the thyroid glan are far more constant in character than any yet described i the nervous system and it is the most obviously disease organ to be found in a case of exophthalmic goitre. I nearly all cases of exophthalmic goitre there is a palpabl enlargement of the thyroid gland. On looking through m case-books I find notes on 70 cases of exophthalmic goitr which I have seen during the last nine years in the North o England where the disease is not uncommon. Of thes cases eight were men and 62 were women All th eight men had enlargement of the thyroid; of the 62 wome all except three had enlarged thyroid glands. Taking bot sexes together we find that only 4 3 per cent. of these case had no goitre. It has been shown by Maude that in som cases enlargement of the gland may be present at one tim and not at another, so that even in those three cases whic were only seen a few times there may have been som enlargement at some other time during the course of th disease which had escaped observation. In any case, in 9 per cent. of my cases there was either enlargement of th gland at the time when the case was seen or there was distinct history of enlargement at an earlier stage.

The enlargement of the thyroid gland in exophthalmi goitre is as a rule uniform. In cases of long duration it may be irregular in shape and consistence owing to the develop ment of fibrosis leading to the formation of irregular strand and masses of hard fibrous tissue in some parts of the gland The veins on the surface are large and their walls are thin In well-developed cases the goitre is very vascular and the arteries are dilated and tortuous, indicating that there was liberal supply of blood during life. On section the cu surface presents a uniform appearance; it is lighter in colou and exudes less colloid than a normal gland. The microscopical appearances have been very clearly described by Greenfield,[8] Stewart and Gibson,[9] Edmunds,[10] and Abram.[11] The general appearance is that of a gland in a state of great secretory activity and has been aptly compared by Greenfield to that of the mammary gland during lactation. The number of alveoli is not only increased by the total increase in size of the gland but in equal areas more secreting tissue is seen than in the normal gland. In many places the lumen of the alveolus is irregular in outline owing to folds of the alveolar wall covered with epithelium projecting into it, so that even when the gland is but slightly enlarged there is a marked increase in the amount of the secretory epithelium. The lumen of the alveolus is in consequence diminished in size in some cases to a considerable extent. The actively secreting part of the gland is thus increased at the expense of the storage room which is so ample in the normal gland. The epithelium which lines the alveoli and covers these folds is changed in type, for the cells instead of being flat or cubical are tall and columnar. There is less secretion to be seen lying in the and a free exit is provided for any secretion which may find its way into the wound, such symptoms will in all probability but seldom arise.

[11] THE LANCET, Nov. 16th, 1895.

It is now well known that thyroid extract has a bad effect on patients with exophthalmic goitre. Under its influence the pulse becomes more frequent and the other symptoms are increased. In some instances where other treatment had been followed by marked improvement the administration of thyroid extract has been followed by a relapse into the former condition. In my opinion it should never be given in exophthalmic goitre as it is *only adding fuel to the fire.* The results of surgical treatment of exophthalmic goitre undertaken with the object of reducing the amount of secreting tissue by removal of one lobe, or of inducing atrophy by ligature of some of the arteries which supply the gland, are of great interest. Unfortunately, the operation itself though sound in principle is at present by no means free from risk. The steady improvement, however, which has resulted in many cases in which it has been successfully performed affords still further evidence that the symptoms of exophthalmic goitre are due to the over-activity of the thyroid gland.

It is a fact of considerable interest that along with the enlargement of the thyroid gland in exophthalmic goitre other ductless glands may be increased in size. The thymus gland is very often enlarged; in all the cases recently examined at St. Thomas's Hospital Dr. H. Mackenzie[18] has found the thymus persistent and enlarged, the microscopical structure being normal. Exophthalmic goitre and acromegaly are sometimes found to occur together. I have recorded two examples of this and collected records of three others.[19] In acromegaly the pituitary gland is enlarged and the enlargement seems to be analogous to that of the thyroid in exophthalmic goitre, so that we have the remarkable fact that all these three ductless glands may be simultaneously enlarged. We know no explanation of this but it suggests that possibly some common factor may be the cause of the enlargement. That some association exists between the thyroid and pituitary glands is further shown by the enlargement which takes place in the latter when the former is removed or disabled by disease.

These facts all indicate that in the treatment of exophthalmic goitre attention should be directed to the thyroid gland. Time will not permit me to discuss the question of operative treatment, but there can be little doubt that removal of part of the enlarged gland is a rational method of treatment and when the risks of the operation are diminished it should be more frequently employed in severe cases in which medical treatment has failed to do good. Of medical treatment much has been written. In my own cases inunction of red iodide of mercury ointment over the goitre and belladonna given in large doses internally so as to check the hypersecretion of the gland have been of most service. If the palpitation is excessive convallaria has proved more useful than any other member of the same group of drugs. Where there has been great nervousness the bromides have done good. In only one case have I seen decidedly good effects from taking thymus. In this case three tablets of dried thymus were taken each day for nine months, for the last six and a half of which the red iodide of mercury was used as well. As a result of this treatment the pulse-rate, which varied from 132 to 143, fell to 84; the thyroid gland, which had been considerably enlarged, returned to its normal size; the tremor became much less; and the exophthalmos was diminished.

In conclusion, Mr. President and gentlemen, allow me to thank you for the kind help which you have given me by your attention in my endeavour to place before you some of the facts which help to explain the function of the thyroid gland and the practical uses to which such knowledge can be put in the treatment of disease, and I trust that the wishes of the founder of this lectureship have thus been carried out in the spirit, if not in the actual letter of his bequest.

THE BRISTOL MEDICAL MISSION.—The annual meeting of the Bristol Medical Missionary Society was held on March 9th under the presidency of the High Sheriff (Mr. O. Wills). The honorary secretary reported that during 1898 7536 out-patients had been treated and 1880 patients had been visited at their homes. The total income for the year was £732 and the expenditure amounted to £695.

ABSTRACTS OF

Three Lectures

ON

THE JOINTS OF MAMMALS CONTRASTED WITH THOSE OF MAN.[1]

Delivered before the Royal College of Surgeons of England on March 6th, 8th, and 10th, 1899,

BY F. G. PARSONS, F.R.C.S. ENG.,

HUNTERIAN PROFESSOR.

LECTURE I.

Delivered on March 6th, 1899.

IN this lecture the temporo-maxillary and shoulder-joints as well as the articulations in connexion with the clavicle were treated. In the temporo-maxillary joint special stress was laid on the fact that in man the external lateral ligament of the jaw ran downward and backward and was attached below to the posterior part of the outer side of the neck of the condyle. The occasional appearance of a post-glenoid process in man's skull was pointed out as well as the fact that the long axes of the condyles ran backward and inward. In the lower Primates it was shown that the glenoid cavity became more and more flattened by the non-appearance of the eminentia articularis or pre-glenoid process, while the post-glenoid process was *constantly present* and was situated *only* at the outer part of the back of the cavity in the catarrhine monkeys. In the lemurs, on the other hand, it was directly behind the centre of the condyle and in these animals the long axis of the condyle was quite transverse.

The suggestion was made that *the obliquity of the transverse axis of the condyle in man was due to the fact that in the higher Primates the post-glenoid process checked the backward movement of only the outer part of the condyle.* The backward direction of the external lateral ligament was found to be present in monkeys as in man, and it was shown that when the mouth was opened this ligament became tense and checked the backward movement of the neck of the condyle; the jaw was then converted from a hinge into a lever of the first class and the condyle moved forward on to the eminentia articularis without the necessity for any action of the external pterygoid muscle. The various mechanisms of the jaw in the different orders of the Mammalia were then dealt with in detail, and among other things it was shown that the inter-articular meniscus was present in all mammals until the Edentata were reached in descending the scale. In this order the structure was shown to be absent in the armadillo as it was also in the Tasmanian devil (Dasyurus) among the Marsupialia. In the Monotremata it was also wanting. This absence of the meniscus among lower mammals the lecturer regarded as telling against the likelihood of its representing the quadrato-jugal bone of lower vertebrates and he inclined to the belief that it was simply a pad adapting the joint to various different kinds of movement. In reviewing the clavicular articulations it was pointed out that when a clavicle was present it was connected with the dorsal side of the presternum and that in a generalised mammal there was usually a rod of cartilage which connected the two bones. In this rod an ossified nodule was frequently found and this the lecturer regarded as the homologue of the sternal epiphysis of the clavicle of the Primates. Synovial joints might be developed between the cartilaginous rod and the sternum and in some instances between it and the bony clavicle. The inter-articular fibro-cartilage of man was shown to be a constant structure in the Primates and the possibility of this being a mere fibrous ingrowth from surrounding tissues to adapt the joint to various kinds of movement was discussed. The coraco-clavicular ligament, it was stated, was single below the higher Primates and in some animals—e.g., Dasypus and Bradypus—was very long. The acromio-clavicular joint existed only when the clavicle was fully ossified, otherwise the bony ends were connected by fibrous tissue which in the case of the three toed sloth (Bradypus) had entirely disappeared

---

[1] These lectures will be published in full in the Journal of Anatomy

In the shoulder the coraco-humeral ligament was described as being peculiar to the Primates and the lecturer's experience made him think that it had little or no morphological connexion with the distal end of the pectoralis minor The three gleno humeral ligaments of man were called attention to and it was stated that the inferior one was unsatisfactory and difficult to recognise The tendon of the biceps in man was free in the joint cavity, but in every other mammal in which it was intracapsular a reflection of synovial membrane passed from its ventral border to the ventral part of the capsule The lecturer stated his opinion that the upper of the three gleno humeral ligaments in man, lying as it did anterior (ventral) to the tendon of the biceps, was the remains of the reflection which in other mammals connected the biceps with the capsule The middle gleno humeral ligament of man was shown to be more or less persistent all through the mammalian class, sometimes, as in Rodentia, being very prominent and sometimes indistinguishable but always when present running from the attachment of the biceps tendon to the lower part of the lesser tuberosity of the humerus A ligament corresponding to it in position was shown in the shoulder joint of the Monotremata and it was pointed out that this ligament was of great functional importance in the mechanism of the joint of those animals

LECTURE II

Delivered on March 5th 1899

IN this lecture the elbow, wrist, and hip joints were dealt with In the elbow the presence of an oblique ligament passing from the internal condyle to the radius just behind the tubercle was noticed and the name of "oblique radio-humeral ligament" was suggested for it It lay superficial to the capsule and checked pronation It was frequently found among the Primates, Carnivora, and Rodentia A distinction was drawn between the elbow used only for support and that used for prehension The ungulate elbow was taken as a type of the former and it was noticed that the radius lay entirely in front of the ulna, that its head was transversely elongated, that there was no orbicular ligament, and that the lateral ligaments were both attached to the radius The human elbow was taken as a type of the form adapted to prehension and drawn attention to, and it was shown that in the lower Primates these were less well seen and that in other mammals they were not present at all The lecturer had been unable to find any evidence supporting the theory that the ilio femoral ligament represented a degenerated scansorius or gluteus quartus muscle, he regarded the ligament in question as a thickening of the capsule due to the gradual assumption of the erect posture The presence of the ligamentum teres was next drawn attention to and it was shown to be absent in the orang, many Insectivora, the Pinnipede Carnivora, a few of the Ungulata, some of the Edentata, and both examples of the Monotremata The lecturer expressed his ignorance of the factors which determine the presence or absence of this structure, but stated that it did not necessarily vary with the presence or absence of the gleno humeral ligament of the shoulder In the Cape hyrax and the armadillo the ligament was shown to be continuous with the pubic portion of the capsule instead of being free in the joint, while in some animals, such as the horse, goat, hyrax, and Cape jumping hare, it was continuous through the cotyloid notch with extra capsular structures—a fact tending to confirm Sutton's view that the ligamentum teres was the remnant of an extra capsular muscle

LECTURE III

Delivered on March 1[illegible]th 1899

IN this lecture the knee and ankle joints were described. In dealing with the lateral ligaments of the knee it was shown that in almost all mammals the fibres of the external lateral ligament showed a twisting in such a way that those attached posteriorly to the femur became superficial as they descended and finally were the most anterior at their attachment to the fibula In some animals a twist in the opposite direction was evident in the internal lateral ligament The low attachment of the internal lateral ligament was shown to favour rotation and in the bat's knee, which was a perfect hinge, it was pointed out that the lateral ligaments were attached just below the joint cavity In the armadillo, which had very free rotation of the knee, the internal lateral ligament was attached to the middle of the shaft of the tibia The oblique ligament of Winslow was stated to be practically a human characteristic Five varieties of the ligamentum mucosum were demonstrated (1) in which it was quite unconnected with the femur as in the lemur, (2) in which it was feebly connected with the femur, as in man, (3) in which it formed an antero posterior partition between the two condylo tibial articulations, as in many monkeys and the otter, (4) in which it completely subdivided the knee into three joints, two condylo-tibial and a trochleo patellar, as in the three-toed sloth (Bradypus) and the Ornithorhynchus, and (5) in which it subdivided the knee into two unequal joints, the condylo tibial of one side being shut off from the rest as in not at all improbable that the kidney has an internal secretion, though absolute proof is not yet forthcoming. In some few cases in which I have used the renal extracts they have been followed by an increase in the amount of urine and an improvement in the general condition. The use of renal substance extracts is still in a purely experimental stage. Judging by the analogy of myxœdema, it would be in the cases of chronic renal cachexia only that we should look for striking results, and this requires early and correct diagnosis. In acute uræmia there is so little time to act that recourse must be had to other and more active measures.

The task set before me is finished. My choice of granular kidney was inspired by the hope that what had interested me might prove of interest also to others. I trust I may not have misjudged. I have not hesitated to express my own opinions, even at the risk of appearing egotistic, though I trust with sufficient modesty to escape the charge of dogmatism. On a subject so full of difficult and contentious questions I cannot expect that my views will commend themselves to all. Yet defined opinions challenge criticism and criticism tends to advance knowledge.

PARALDEHYDE AS A RESPIRATORY SEDATIVE.

BY WILLIAM MACKIE, M.A., M.D. ABERD.

SINCE I first suggested the use of paraldehyde in spasmodic asthma,[1] now over six years ago, I have had frequent occasion to administer the drug both in purely functional respiratory troubles and in dyspnœic conditions arising from various causes, in many cases even where complicated with grave organic lesions. In no case where I have used it have I ever had occasion for regret, but, on the other hand, have always been pleased, and often more than pleased, with the result. I am glad to find that Dr. Macgregor[2] has found it equally satisfactory in the cases in which he has used it. I may say that the suggestion of its use in asthma has not been altogether a dead letter. Dr. Hearder,[3] of West Riding Asylum, Wakefield, in 30 cases of asthma, many of which were complicated with severe organic disease, found that it came quite up to the level of expectation and I have on several occasions had private inquiries from medical men as to the propriety of prescribing it in particular cases. To those I have uniformly replied that paraldehyde is a safe drug and may be freely given under almost all circumstances. So assured of its value in dyspnœic conditions generally have I become that I have long ceased to take notes of particular cases, but the two following, both of which were complicated with grave organic lesions, come fairly within the range of memory.

CASE 1.—A woman, aged 34 years, with chronic kidney disease (large white) for some years in the last stages suffered from gradually increasing œdema of the lungs with corresponding dyspnœa, restlessness, and eventually sleeplessness. After failure of the admissible hypnotics (sulphonal being one) and sedatives in what was considered legitimate doses, one drachm of paraldehyde given diluted in water repeatedly gave three or four hours' sleep without perceptibly affecting the other symptoms but to all appearance with much temporary relief.

CASE 2.—A spare but plucky woman, aged 50 years, had from the month of June of last year onwards much dyspnœa with bronchial spasm and some expectoration. She had had to my knowledge for at least six years valvular disease of the heart, both aortic and mitral, but this was the first appearance of anything like marked dyspnœa. The case was in the circumstances one of some anxiety and a consultant who saw the case at an early stage "ventured to hope" that the attack might prove a temporary one, but neither of us had really much hope of eventual recovery. Many drugs were tried with little result. At last the following formula was hit on: one drachm of tincture of strophanthus; eight minims of solution of nitro-glycerine; 36 minims of solution of strychnia; one and a half drachms of paraldehyde; and one and a half ounces of infusion of calumba. One drachm of the mixture in water to be taken occasionally but not oftener than once in six hours. This from the first gave marked relief. During an illness of six months the woman clung tenaciously to the "little bottle" and from time to time had the mixture repeated. For the last two months she has been able to be about again and for that time has required nothing. It might be doubted whether the paraldehyde in the above mixture was to be credited with the result, but from close observation of the case I am strongly of opinion that it was the paraldehyde which gave the relief.

As with most drugs of the kind I have found paraldehyde when frequently exhibited in the same case eventually fail to produce results in ordinary doses, but I am decidedly of opinion that this tendency is much less marked in the case of paraldehyde than of many other drugs. In some cases, however, no such tendency has been observed after prolonged use. I have never seen fainting on its exhibition, as occurred in some of Dr. Macgregor's cases, but I have usually prescribed it mixed with equal parts of syrup of orange peel or syrup of hemidesmus and always ordered it to be given freely diluted with water. Where tinctures are present, as noticed by Dr. Hearder, it becomes fairly miscible in water with other drugs.

FURTHER STATEMENT AS TO RESULTS OBTAINED BY OPERATION FOR CANCER OF THE BREAST.

BY W. WATSON CHEYNE, M.B. EDIN., F.R.C.S. ENG., F.R.S.,
PROFESSOR OF SURGERY IN KING'S COLLEGE; SURGEON TO KING'S COLLEGE HOSPITAL, ETC.

THREE years have now elapsed since I published in the Lettsomian Lectures and subsequently in THE LANCET[1] the results which I had up to that time obtained by extensive operation in cases of cancer of the breast, the operations being carried out in accordance with the pathological and anatomical facts contained in the researches of Heidenhain and Stiles. At that time I was able to mention 61 cases which had been operated upon at periods varying from one month to six years; in 21 of these from three to six years had elapsed since the date of the operation. As three years and more have now elapsed (from three to nine years) since these 61 cases were operated upon it seems to me desirable to state as far as I can what is their present condition. I need not reprint the list of cases here, the numbers which I give are those under which the cases are described in the former paper in THE LANCET.

In the first place, let us take those cases in which at the time of my last publication three years or more had elapsed since the date of the operation. These were 21 in number, and it will be remembered that at that time recurrence had taken place in nine, while on the other hand 12, or 57 per cent., had remained well for over three years. Of the latter, 11 were at that time alive and well and one had died from acute bronchitis, without any trace of recurrence of the disease, three years and five months after the date of the operation. At the present time nine of these patients are, I know, still alive and well. One I knew of up till about a year ago, when she was also well, but she has left her former address and I have not yet been able to trace her. One only has died, and the cause of death is stated to have been hæmorrhage from cancer of the intestine; apparently there was no recurrence in the region of the breast. The following are the cases, giving the time which has elapsed since the operation.

No. 1 (*of former report*). Alive and well; nine years. 4. Reported to have died from cancer of the intestine about six years after the operation. 5. Alive and well; eight years and three months. 6. Alive and well up to a year ago (seven years); since lost sight of. 11. Alive and well; seven years and three months. 13. Alive and well; seven years and two months. 14. Alive and well; seven years and one month. 15. Alive and well; seven years and one month. 16. Alive and well; six years and 10 months.

---

[1] THE LANCET, Feb. 15th and 22nd and March 14th, 1896.

19 Alive and well, six years and one month 21 Alive and well, six years

The results thus remain very much the same as before In only one case has the disease reappeared in those who were well three years ago and from what I hear it is quite possible that this may have been a fresh cancer altogether and not a recurrence of the one removed from the breast I may add that quite recently a patient on whom I had operated in October, 1889, came to the hospital for another trouble altogether and was quite well as far as any sign of cancer was concerned, and still remains so, and if this case be added to the above list my percentage of successes remains practically the same as in my former paper

Let us take next the cases in which at the time of my last publication three years had not yet elapsed since the operation These were 40 in number, and at that time 10 had shown signs of fresh disease (it may be remembered that one of these was really an inoperable case and that in one I only assumed from what I was told that there was a recurrence, further, apart from the inoperable case, several of them were very bad cases to start with) one died from the operation two had been lost sight of and 27 had not then had any recurrence Let us trace the fate of these 27 cases

No 26 Cannot trace her 27 Alive and well, five years and three months 30 Alive and well, four years and 11 months 31 Alive and well, four years and 10 months 32 Alive and well, four years and 10 months 35 Alive and well four years and eight months 37 Died from internal recurrence about two and a half years after the operation 39 Alive and well, four years and four months 40 Alive and well four years and three months 42 Alive and well, three years and nine months 43 Alive and well, three years and seven months 44 Alive and well, three years and seven months 45 Alive and well, three years and seven months 46 Alive and well, three years and seven months 47 Alive and well, three years and six months (a very bad case) 48 Died from recurrence 49 Died from recurrence 50 Alive and well, three years and six months 51 Died from influenza and acute pneumonia two and a half years after the operation No sign of external or internal disease 53 Died from recurrence internally about 18 months after operation 54 Alive and well, three years and four months 55 Alive and well, three years and four months 57 Died from recurrence 58 Died, recurrence (?) 59 Alive and well, three years and two months 60 Died 18 months after the operation, recurrence in liver (a very bad case) 61 Alive and well, three years and one month

Thus of the 27 patients who had had no recurrence at the time of my last publication, 18 are still alive and well and one died without recurrence In other words of the 37 patients who lived after the operation and the fate of whom can be traced 19, or over 50 per cent, remained free from recurrence 16 certainly had recurrence one probably died from recurrence and in one I do not know the result This gives us a total in the 61 cases of 30 patients who remained free from recurrence, 29 of these having passed the three years limit, one died from the operation and three have been lost sight of The results therefore in cases where they are ascertainable are about 51 per cent of successes—i e, of patients remaining alive and well for over three years

As regards the value of the three years limit—or indeed, of any time limit—it is interesting to note that of the 11 cases alive and well at the time of the last report (three years or more after the operation) only one has shown signs of fresh disease and it is doubtful whether that was a recurrence or a new development Further of the 20 patients alive and well at the time of the last report one year or more (from one year to six years) after the operation 17 still remain well This shows the great chance of freedom which patients alive and well a year after the operation have gained by the thorough procedure which I advocate

It may be of interest if I add a further list of the patients operated upon up to the end of 1897 which brings the totals up to 99 I need not give the more recent cases as up to a year the chances of recurrence still remain considerable while after a year they are comparatively slight as has just been shown

I may say that the statements as to prognosis in this list represent the impression left on my mind at the conclusion of the operation and which I put down at the time It refers essentially to the state of matters found as regards the breast glands &c, and was hardly influenced by other considerations such as the age of the patient, the duration of the disease, &c

The result of these 38 fresh cases in which from one to three years have elapsed since the operation is the following,—26 patients remained well without recurrence, one refuses to say how she is but appears well, in one the result is unknown, one died suddenly about a fortnight after the operation, seven died from recurrence, one (in whom there had been recurrence) has probably died, and one (in whom also there had been slight recurrence) has been operated upon and appears well The total is 99 cases in which from one to nine years have elapsed since the operation and of these 56 certainly have as yet had no recurrence

It will be quite evident from the nature of the cases described that there has been no selection of cases from the point of view of obtaining good results by operation A number of the patients operated upon were, to my mind, cases in which it was very doubtful whether an operation should be performed or not and I could easily by selection of cases have obtained a very much higher percentage of successes I had only to refuse to operate on the cases in which the prognosis seemed to me to be bad as indicated in the above list and the result would have been over 80 per cent of successes But such selection, however it might help to establish the operation, would not have been fair to the patients and in several instances where I have thought that early recurrence must take place I have been agreeably surprised to find that the patients remain well As a matter of fact I have only refused to operate upon patients in whom it was evident that removal of the disease was quite impossible either on account (1) of the presence of internal deposits, or (2) of deposits externally in situations which were irremoveable (as, for example, in the ribs, in glands behind the sterno-mastoid, &c) or (3) of extreme weakness Short of that I think that every patient should have the chance of operation even although the local disease seems to be so extensive that the probability of the existence of internal deposits is very great and, as I have just said, I have been agreeably surprised in several instances to find that the patient remains well

I need not again describe in detail the operation which I perform as I have already done so on more than one occasion, but there are some points with regard to it on which I should like to lay stress

Exploratory incisions—One not unfrequently meets with cases in which, either on account of the early period of the disease and the consequent small [illegible]ze of the growth or on account of the great size of the b[illegible]st the deep-seated position of the growth and the diffic[illegible] in manipulating it or, again, on account of the very diffu[illegible] and extensive nature of the growth there is considerable doubt as to the diagnosis Under such circumstances an exploratory operation is of course proposed, and considering the great importance of early operation in cancer an exploratory operation should be at once proceeded with instead of waiting to see what the effect of external or internal remedies would be The operation however, should not be an exploratory *incision* into the swelling If an incision is made into a cancer the cancer cells escape from the alveoli in which they are present soil the knife the fingers of the operator, the skin of the patient and the surroundings generally, and the result may very possibly be that the wound made afterwards with the view of removing the breast and glands may be infected by cancer cells which have escaped from the incision This is not by any means a purely theoretical danger I have already referred to cases of auto infection in my Lettsomian Lectures and I have since on more than one occasion had similar experiences more especially where glands have burst during removal and where the result has been a diffuse cancerous infection of the wound in spite of the greatest care having been taken to clear out all the material which had escaped from the gland Hence, in the case of an exploratory operation the suspected swelling should be *excised along with an area of apparently healthy tissue around* and it should only be cut into after its removal from the body and from the vicinity of the operation It is best if it can be managed, that the incision into the swelling should be made by someone who is not directly associated with the operation afterwards or if it be made by the surgeon that he should not touch it with his fingers and should afterwards discard the instruments which have been employed Should the swelling

SECOND SERIES OF CASES OF CANCER OF THE FEMALE BREAST, 1896 and 1897 (VERIFIED BY MICROSCOPICAL EXAMINATION), IN WHICH THE FIRST OPERATION WAS PERFORMED BY MR. WATSON CHEYNE.

No.	Age.	Date of operation.	Nature of case.	Result.
62	37	11/3/96	Extensive scirrhus of right breast below and internal to nipple. Adherent to skin and muscle. Two other nodules in breast. Numerous glands in axilla and also in posterior triangle of the neck. Swelling (fibro-adenoma) in left breast. Noticed for three years. Very bad prognosis.	Recurred locally and generally within a year. Inoperable.
63	40	8/4/96	Scirrhus behind the left nipple of the size of a two-shilling piece; adherent to skin but not to the deeper parts. Several glands of moderate size in the axilla. Noticed for five months. Fair prognosis.	Alive and well; two years and 10 months (a cyst was removed from the right breast in August, 1898, but there was no sign of cancer anywhere).
64	42	15/4/96	Seen six weeks before with large scirrhus in right breast, but as the patient was just going to be confined the operation was deferred. On returning the swelling had increased in size, there were large glands in the axilla, and there was a suspicion of a deposit in the liver. Disease noticed for ten weeks. Very bad prognosis.	Died from cancer of the liver six months later.
65	51	29/4/96	Scirrhus of left breast about the centre, involving skin and muscle. A good many glands. Noticed for several months. Bad prognosis.	Alive and well; two years and nine months.
66	43	6/5/96	Pretty large scirrhus behind nipple. Glands only slightly affected. Noticed four months. Good prognosis.	Alive and well; two years and nine months.
67	61	2/6/96	Scirrhus at outer part of breast. Some small glands. First noticed two months ago. Good prognosis.	Alive and well; two years and eight months.
68	42	3/6/96	Very diffuse thickening of right breast occurring very rapidly. I was uncertain of the diagnosis and therefore excised a portion of the thickened tissue. Even with the naked eye I was still not sure of the diagnosis as between tubercle and cancer. Microscopical examination showed a rapidly-growing cancer. The breast and glands were therefore removed some days after the exploration. *Very bad case.*	Recurred in sternum and internally in the pleura and mediastinum. Died one year and two months after the operation.
69	71	10/6/96	Small scirrhus at the outer side of left breast. Several small glands. Noticed two months. Good prognosis.	Continued sickness and retching after the operation for several days and a good deal of flatulent distension. No rise of temperature. Stitches removed on June 19th. Patient allowed to get up on a couch on June 20th. Shortly after getting up became livid and collapsed; recovered when put back to bed. At 8.30 P.M. on the same day was seized with severe dyspnœa and died in two minutes. On post-mortem examination there was a clot in the right ventricle extending into the pulmonary artery but not adherent. There was no sign of pulmonary embolism. There was old-standing tuberculous disease of the lungs. There were healed cavities in the lungs and adhesions between the lungs and the chest wall. The colon was much distended. There was extensive diffuse thickening of the wall of the sigmoid flexure and rectum, so that the lumen of the bowel was in parts very narrow. There was no sign of cancer internally.
70	49	10/6/96	Scirrhus above the right nipple of the size of a Brazil nut. Puckering of skin. Numerous small glands. Noticed 18 months. Fair prognosis.	Alive and well; two years and seven and a half months.
71	67	23/6/96	Small scirrhus in upper and outer quadrant of left breast. Good many glands in axilla. Noticed a month. Good prognosis.	Alive and well; two years and seven months.
72	55	23/6/96	Large cancerous mass in centre of right breast, adherent to the skin. A good many moderate-sized glands. Noticed for six months. Bad prognosis.	Alive and well; two years and seven months.
73	60	1/7/96	Small scirrhus at outer side of right breast. A good many small glands. Noticed five weeks. Good prognosis.	Alive and well; two years and seven months.
74	49	19/9/96	Scirrhus at outer part of left breast of the size of a Brazil nut. Several small glands. Only noticed a fortnight ago. Good prognosis.	Alive and well; two years and four and a half months.
75	40	2/10/96	Extensive diffuse scirrhus of left breast with large glands in axilla. Only noticed recently. Very bad prognosis.	Recurrence externally and internally; died in about nine months.
76	49	9/11/96	Small scirrhus to inner side of the right nipple. Two or three glands. Noticed for six months. Good prognosis.	Alive and well; two years and three months.
77	40	17/11/96	Very extensive diffuse scirrhus of the breast. Axilla full of glands and some in the posterior triangle of the neck. Very bad prognosis.	Recurrence in abdomen; died four months later.
78	53	15/12/96	Swelling in left breast just above nipple of the size of half-a-crown. A few small, hard glands in axilla. Noticed for two years. Doubtful prognosis.	Alive and well; two years and one and a half months.
79	43	16/12/96	Diffuse cancer in right breast. Large glands in axilla. Arm painful and swollen. Noticed 18 months. Bad prognosis.	Small nodule noticed in region of scar last November. Removed. Patient looks well and has no further sign of recurrence.
80	53	16/12/96	Large tumour in left breast with large glands. Noticed for six weeks. Bad prognosis.	Died from recurrence internally (lungs, &c.) one year and nine months later.
81	39	16/12/96	Large scirrhus involving upper and inner segment of right breast, adherent to muscle. Large glands in axilla. Noticed for 10 months. Bad prognosis.	Alive and well two years and one month.
82	58	5/1/97	Large scirrhus of left breast at upper part. Glandular affection only slight. Doubtful prognosis.	Alive and well; two years and one month.
83	35	27/1/97	Largish tumour towards centre of breast. Several small glands. Bloody discharge from nipple noticed for a year and swelling for several months. Doubtful prognosis.	Alive and well; two years.
84	45	4/2/97	Diffuse scirrhus of left breast. Several nodules in the breast. Axilla full of glands. Glands also removed from the posterior triangle of the neck, but apparently not diseased. Very bad prognosis.	Alive and well; two years.
85	38	10/[illegible]/97	Scirrhus at lower part of left breast ulcerated, glands moderate in size and few. Noticed some months. Doubtful prognosis.	Alive and well; one year and 10½ months.

SECOND SERIES OF CASES OF CANCER OF THE FEMALE BREAST, 1896 AND 1897 (VERIFIED BY MICROSCOPICAL EXAMINATION), IN WHICH THE FIRST OPERATION WAS PERFORMED BY MR. WATSON CHEYNE—(*Continued*).

No.	Age.	Date of operation.	Nature of case.	Result.
86	39	11/3/97	Very extensive diffuse scirrhus of left breast. Glands only slightly affected. Bad prognosis.	Has become a "Christian scientist" and "does not search for disease." Has seen no medical man since the operation. Will not say anything as to her health but leads an active life. Looks well and there is presumably not much the matter with her.
87	40	15/3/97	Small scirrhus in left breast. Several small glands in axilla. Noticed for a few weeks. Good prognosis.	Alive and well; one year and 10½ months.
88	65	16/3/97	Small scirrhus in left breast and small glands. Noticed a week ago. Good prognosis.	Alive and well; one year and 10½ months.
89	43	14/4/97	Scirrhus of the size of a walnut in lower and inner part of left breast, adherent to pectoral. Small glands in axilla. Noticed four months. Fair prognosis	Alive and well; one year and nine and a half months.
90	51	27/6/97	Large mass in left breast and large glands in axilla. Noticed six months. Bad prognosis.	Died from cancer in the liver about 11 months later.
91	61	1/7/97	Small scirrhus in upper part of right breast, adherent to muscle. Glands small. Noticed six months. Good prognosis.	Alive and well; one year and seven months.
92	50	3/7/97	Tumour of the size of an egg in upper part of right breast, adherent to skin. Glands not much affected. Noticed two years. Doubtful prognosis.	Has left former address and cannot trace her.
93	58	3/7/97 10/7/97	Scirrhus in both breasts; on the left side large ulcerated, and adherent to the muscle; on the right side a small mass. Glands in both axillæ, largest on the right side. The left breast noticed for 10 months. The breasts removed at a week's interval. Bad prognosis.	Alive and well, one year and seven months.
94	47	9/7/97	Small tumour in breast and small glands. Good prognosis.	Alive and well, one year and seven months.
95	42	14/7/97	Fairly large scirrhus in upper part of left breast. Glands noticed for five months. Good prognosis.	Died from recurrence in mediastinum and pleura 14 months later. No external recurrence. Post-mortem examination showed numerous masses of cancer in both lungs varying in size from a pea to a two-shilling piece. Left lobe of the liver also diseased. Double aortic disease.
96	64	13/10/97	Largish mass in centre of breast. A good many glands. Noticed five months. Doubtful prognosis.	Alive and well; one year and three and a half months.
97	45	13/11/97	Diffuse cancer at outer part of left breast and a smaller nodule towards the inner side. Many glands, but small. Noticed nine months. Good prognosis.	Alive and well, one year and two and a half months.
98	40	12/11/97	Small scirrhus of right breast and a few glands. Noticed two months. Good prognosis.	Alive and well; one year and two and a half months
99	60	24/12/97	Small scirrhus behind nipple. Large glands in axilla. Noticed six months. Doubtful prognosis.	Alive and well; 13 months.

turn out to be a cyst or a patch of mastitis the excision which has been carried out is the best possible procedure and, on the other hand, should it be a cancer there is less risk of infecting the subsequent wound by excision than by incision. It is of course possible that, even where the tumour is excised as described, lymphatic vessels containing cancer cells may be cut across, but the cells in these lymphatic vessels are few and as a rule more adherent than in the original growth, and they are therefore less likely to be spread over the surface of the wound. Nevertheless, it is well in all cases after exploratory operations to take special precautions against the subsequent infection of the wound and when a tumour has been removed and the bleeding has been stopped a small sponge should be stuffed into the wound which is then closely stitched up. The skin, the hands of both the operator and the assistant and the skin of the patient should again be thoroughly disinfected as at first, and the instruments used should be laid aside and not again employed for an operation till they have been thoroughly boiled.

Removal of skin.—One of the most important parts of the operation is the free removal of skin. This should in the first place be carried out quite independently of the question of how the wound is to be closed afterwards, otherwise one is very apt not to take enough skin away. All the skin over the breast proper should be taken away, however small the growth, and where the tumour lies to one side of the breast special incisions must be made around it in order to get well wide of it. In the accompanying figures I have represented some of the incisions which should be employed in cases of tumours situated in different parts of the breast (see Figs. 1 to 5). In these figures the cross indicates the position of the cancer and the dotted lines the lines of incision in each case. The figures speak for themselves but I may note that they are drawings of the virgin breast and that in a large pendulous mamma the lines would be much further apart. The best way of determining the upper line in the latter case is to raise the breast and see where the fulness begins above and make the line of incision about an inch above that unless where the cancer lies towards the upper part when the incision must be in the form shown in Fig. 4.

I believe that in the free removal of the skin lies one of the chief reasons why I have had so seldom local recurrence after my operations. And, further, not only should the skin be freely removed in the manner represented, but the skin incisions when made should not go straight down to the muscle. After the skin incisions have been mapped out, the skin and just sufficient fat to enable it to retain its vitality should be dissected up and the muscular fibres should not be exposed till just below the clavicle above, beyond the middle line in front, over the origin of the abdominal muscles below, and over the edge of the latissimus dorsi muscle behind. The fat with the outlying lobules of the mamma and the lymphatics and vessels contained in it are thus separated from the skin and are then removed along with the fascia or muscle beneath. Another advantage of this free undermining of the skin which is necessary in order to remove the outlying lobules of the breast is that one can generally succeed, possibly with a little extra undermining in places, in bringing the edges of the skin together with the employment of some force. In some cases I have had to skin-graft the surface or part of the surface left, and the results obtained by skin-grafting are most excellent; but in the majority of cases I succeed, in spite of the free removal of skin which I advocate, in stitching up the whole wound. No doubt at first there is some compression of the side of the chest from the skin which is drawn so tightly over it, but in the course of a few weeks the skin gradually accommodates itself and in three or four months the feeling of tightness and the actual tightness of the skin have gone.

Removal of the breast.—What has just been said as to the method of dissecting up the skin indicates to what extent the breast should be removed and I need only remind the reader that the breast extends far beyond any part that can be felt by the fingers, and to remove the breast only as far as one can feel the edge of it, as has been lately suggested, would be to leave breast tissue all around the area of the operation.

Removal of deep fascia.—None of the pectoral fascia or the fascia over the muscles must be left behind in the area of the wound. If the whole muscle is not taken away a superficial layer of it at least must be dissected off so as to insure the proper removal of the fascia and the lymphatic vessels which run in it.

Removal of muscle.—It is about the question of the pectoralis major muscle that the main controversy arises and the chief advocate of the removal of the whole of the pectoralis muscle, at least of the whole of the thoracic origin of the muscle, is Halsted of Baltimore. In fact, it is practically only in this point that his operation differs from mine. I remove the lower part, say half of the muscle, in all cases—that is to say, all the muscle which lies behind the cancer from a little a the cancer down to its lower edge; and I only take awa whole of the muscle, or even the whole of the pectoral o of the muscle, where there is evident disease of the m itself. Halsted, on the other hand, removes the pec origin of the pectoralis major in all cases, his reaso

FIG. 1.

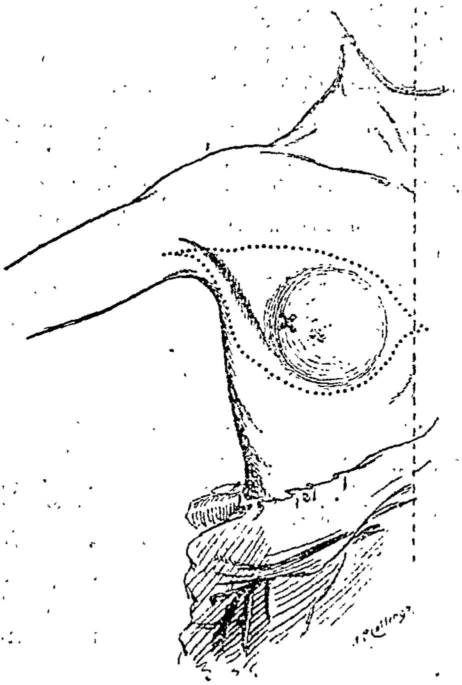

FIG. 2.

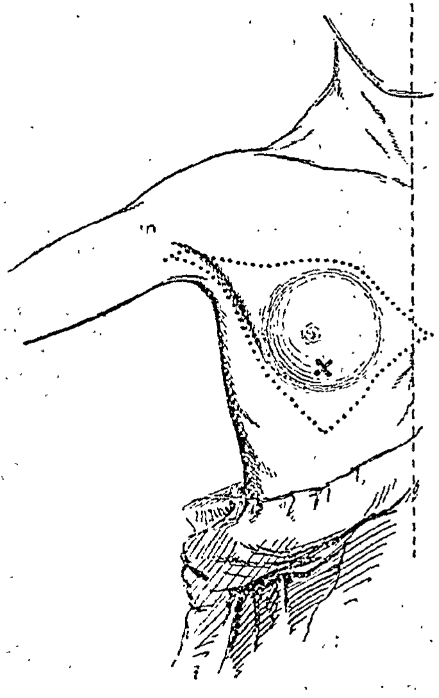

FIG. 3.

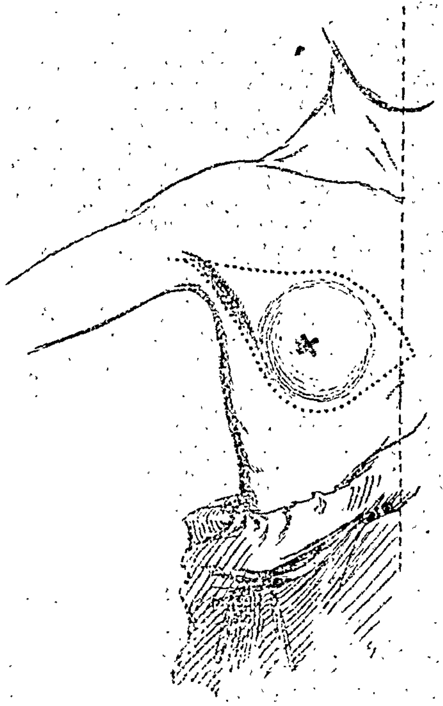

FIG. 4.

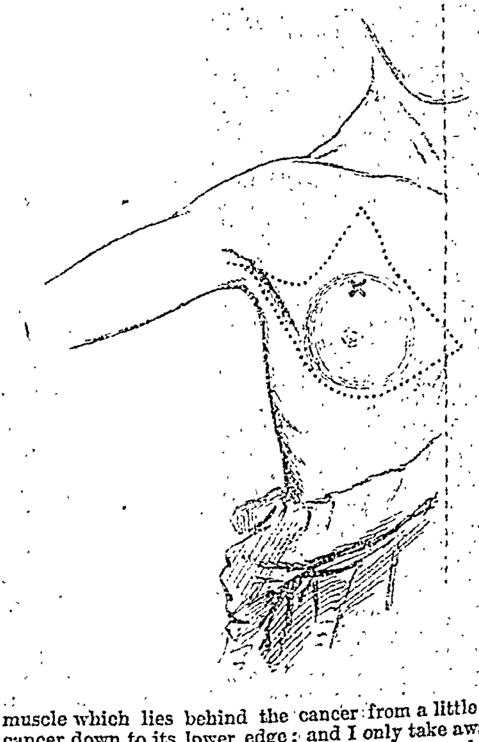
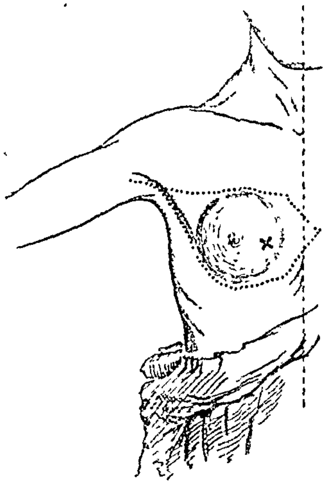


doing so not being so much the removal of diseased tissues as with the view of opening up the axilla fully so as to get away all the glands. Indeed, Halsted goes further and not only removes the pectoralis major but also the pectoralis minor, or at least he divides the pectoralis minor and turns it aside. From the point of view of clearing the axilla I consider that the removal of the whole of the pectoralis major muscle and more especially of the pectoralis minor muscle is quite unnecessary, and I am afraid that the tendency may come to be to attach too much importance to the removal of muscle and too little importance to the removal of the outlying lobules of the breast and of the skin in these operations In my own experience when the lower half of the pectoralis major muscle has been taken away it is quite easy to completely expose the axilla and the removal of the pectoralis minor muscle is quite unnecessary for this purpose. The fascia over the pectoralis minor muscle should of course be removed, as well as that over the pectoralis major, and when it has been detached from the upper and lower edges of the muscle, the muscle which is quite narrow where it passes over the axilla can be pulled upwards and downwards so as to afford a free view of the contents of that space. After detaching the fascia over the under surface of the pectoralis major it can be lifted up so that one can see quite up to the clavicle, and then the costo-coracoid membrane, the fat over it, and the fascia over the pectoralis minor can be removed and one can see right up to the apex of the axilla. The pectoralis minor can be hooked down and one can see behind it at the upper part, and hooked up and one can see behind it at the lower part and thus the whole of the axilla can be easily cleared. I think that my results fully justify my contention that it is unnecessary to remove the whole of the pectoralis major muscle and the pectoralis minor in all cases; in fact, my results are practically the same as those obtained by Halsted.

FIG. 5.



Removal of glands.—The thorough clearing of the axilla is of course an absolutely essential part of this operation. When the lower part of the pectoralis major muscle with the overlying breast has been detached and turned forward, the fascia is dissected off the serratus magnus muscle along with the superficial fibres of that muscle and then separated from the latissimus dorsi and thus the whole of the fat and glands in the lower part of the axilla are raised in one mass up to the level of the vessels. The breast then being allowed to hang over the side, the pectoralis major and minor muscles are held out of the way and the fat is dissected downwards and inwards from the upper part in front of the vessels and nerves till the vein is exposed. The sheath of the vein is then opened and stripped off from the arm up to the apex of the axilla and then the fat and glands below are also detached. In this way the whole of the glands in front of and below the axillary vein are removed and there only remain the glands and lymphatics which run up behind the vessels towards the posterior triangle of the neck. The vessels and nerves must therefore be lifted up, and this mass of fat and glands lying in the triangular space between the vessels in front, the scapula outside, and the chest wall inside, should also be taken away.

Another question which has to be considered is whether and when it is necessary to clear out the posterior triangle of the neck. The lymphatic infection in cases of breast disease follows two lines; in the one case, and that most commonly, the infected glands run up in the immediate neighbourhood of the axillary vein and generally towards the pectoral side of it to the apex of the axilla and thence they pass on to the root of the neck in front, and then probably into the anterior mediastinum; a second course which the lymphatic vessels take is upwards in the fat behind the vessels to the posterior part of the posterior triangle of the neck. This is, as a matter of fact, a decidedly less frequent direction than the former; in fact, in a recent paper Halsted, who now always removes the fat and glands from the posterior triangle of the neck and has them carefully searched microscopically, states that only in about 34 per cent. of the cases in which this has been done has he found evidence of disease in that region. Hence it is clear that it is not always necessary to remove the glands from the posterior triangle of the neck, and as a matter of fact the rule which I follow is the following—assuming, of course, that there is no enlargement to be felt there before the operation. I do not clear out the posterior triangle of the neck unless I find that in the fat behind the vessels running up in the direction of the posterior triangle there are enlarged glands. In that case I assume that the course of the lymphatic disease will tend towards the posterior triangle and that therefore it ought to be cleared out; but where I find no evidence of disease in the fat and glands running up behind the vessels I do not think that it is necessary to prolong the operation and to increase the shock to the patient by opening up the posterior triangle of the neck and, as a matter of experience, I have hardly ever seen a recurrence in the glands of the posterior triangle of the neck.

Another question which arises out of this is how far the presence of infected glands in the neck is a contra-indication to operation at all. Halsted himself does not admit that it is a contra-indication—in fact, he looks forward to a time when not only will the breast and the triangles of the neck be cleared out but also the anterior mediastinum. For my own part I am inclined to doubt whether it is worth while operating on a patient in whom there is marked enlargement of cervical glands and I should put it in this way. If there is enlargement of glands in the posterior part of the posterior triangle I do not consider that that is necessarily a contra-indication to radical operation provided that the patient is in a state to stand a prolonged operation. On the other hand, if at the root of the neck in front of or beneath the sterno-mastoid there are glands of considerable size I do not believe that it is worth while subjecting the patient to a radical operation, for I can hardly think that in such cases the results as regards recurrence will justify it. Although Halsted advocates this procedure there is no evidence in his paper as to the results in the cases in which it has been carried out and without such evidence we cannot, of course, form any opinion on the matter.

After-treatment.—There is one point as regards the after-treatment of these cases which is of very great value and which we owe to the late Mr. Edward Cotterell. Instead of fixing the arm to the side, as was formerly done after the operation, with the result that there was a good deal of contraction and that a considerable time elapsed before the patient could use her arm at all freely, he fixed the arm at right angles to the chest by means of a special splint. This is, I think, a great advantage and I always carry it out, but instead of a splint I find that it is [illegible] to place a large pad of salicylic wool in the [illegible] at about right angles with the [illegible] arm on a pillow. Even after [illegible] keep the arm out from the [illegible] as a right angle, for some deal of the contraction which follows these extensive operations is avoided and the patient recovers the use of her arm much more quickly than when it is bound to the side.

Taking the results which I have given in this paper along with the results obtained by Halsted, Butlin, and a variety of other operators, I think that we are justified in drawing the following conclusions. 1. Taking cases of all kinds together, not merely selecting favourable cases for operation but operating on all cases in which operation is possible with the exceptions which I have already mentioned, we may, I think, reckon that about 50 per cent. of the patients will remain free from recurrence if the operations are carried out on the lines laid down by Heidenhain and Stiles. 2. That even in the cases which do recur recurrence is considerably delayed and the patient enjoys a considerable interval of good health. 3. That the repeated operations which take place after the old operation are now very rare, recurrences when they do appear being usually in inoperable situations. 4. It will be evident from my results that the chance of recurrence is extremely slight after these extensive operations in patients who have remained well for from one to two years, and after three years there is only one example in my list of fresh cancer, and in that case there is no evidence that that was one of recurrence of the original disease rather than a fresh development. 5. I may add my firm conviction that *the patient's chance lies in the first operation.* If this fails, either from imperfect removal of the disease or on account of the extent of the disease in the first instance, further operation, however extensive, is seldom successful. This is my experience. I see a good many cases which have been operated upon elsewhere and in which recurrence has taken place, especially cases in which the old operation has been performed, and in the few in which I have been tempted to give the patients another chance by an extensive operation the results have been almost uniformly disappointing. Where a cancer is quite small patients and practitioners are very apt to be content in the first instance with a small operation thinking that if recurrence takes place an extensive removal can be performed afterwards. This is, I am satisfied, an utter fallacy, and the performance of a partial operation in the first instance takes away the patient's best and often her only real chance of getting rid of the disease.

Harley-street, W.

NOTE ON THE

PRODUCTION OF SYMPTOMS OF THYROIDISM IN A CHILD AT THE BREAST BY THE ADMINISTRATION OF THYROID EXTRACT TO THE MOTHER—I.E., THROUGH THE MILK.

BY BYROM BRAMWELL, M.D., F.R.C.P., F.R.S. EDIN.,
PHYSICIAN TO THE ROYAL INFIRMARY, EDINBURGH; LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE AND ON CLINICAL MEDICINE IN THE SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, EDINBURGH.

IN one of my cases of myxœdema treated by thyroid extract the breasts filled with rich milk during the course of the thyroid treatment. This fact seemed to suggest that thyroid extract might be usefully employed in nursing women with the object of increasing the flow of milk, but the following case in which thyroid extract given to the mother (who was suffering from exophthalmic goitre) repeatedly produced well-marked symptoms of thyroidism in the infant she was nursing shows that the remedy would have to be given for such a purpose with great care and caution. The notes of the case are as follows.

A married woman, aged 34 years, who was nursing her child, aged six months, was admitted to the Edinburgh Royal Infirmary on Dec. 17th, 1894, suffering from exophthalmic goitre. The disease had developed six months previously—i.e., immediately after the birth of the child she was nursing at the time of her admission to hospital. The delivery was easy. The child had clubbed feet; this caused the mother much mental distress, and (? as the result of this mental distress) the symptoms of exophthalmic goitre quickly developed. On admission, with the exception of the clubbed feet the child was normal in every respect. The mother presented all the classical symptoms of exophthalmic goitre. On Dec. 24th thyroid extract (two five-grain tabloids daily) was administered to the mother. On Jan. 1st, 1895, it was noted that "the child has been sweating profusely for several nights past. It is looking ill and has been sleepless. It has vomited every morning for the past three days. Until a few days ago it was perfectly well, and has in fact never been ill since its birth." The question at once arose whether these symptoms in the child were due to the thyroid extract which the mother was taking. The thyroid was consequently stopped for five days. The child immediately improved, was much less restless, slept better, sweated less, and did not vomit. On Jan. 3rd it was noted that "the child is very much better," and on the 4th that "it is perfectly well." On the 9th thyroid extract was again given to the mother. The next day (the 10th) the child vomited, was restless, did not look well, and sweated profusely. The thyroid extract was consequently stopped. On the 12th the child was all right again. On the 13th two tabloids of thyroid extract were again given to the mother. On the 14th the child was again sick, looked ill, sweated profusely, and was restless at night. On the 15th the child was weaned and after this date remained perfectly well until the 25th, when the mother was discharged from the hospital.

Remarks.—There can, I think, be no doubt that in this case the administration of thyroid extract to the mother produced symptoms of thyroidism in the child, the thyroid extract being conveyed to the child through the milk. This was noted on three occasions and it is evident that the point—whether thyroid extract given to the mother can produce symptoms of thyroidism in her child at the breast—is not merely of theoretical but of distinct practical importance.

Edinburgh.

A CASE OF BLACKWATER FEVER COMPLICATED BY DYSENTERY.

BY A. T. WOOLDRIDGE, L.R.C.P. LOND., M.R.C.S. ENG., L.S.A.

THIS case presents some features of special interest; it is that of an officer, aged 26 years, who was in Ceylon in 1892 on a shooting expedition and there developed malarial fever. He had fever on the ship all the way home but did not lie up. On arriving in England he had a bad attack of malaria. In August, 1897, he went out to the Niger and was there only six weeks when he was attacked with dysentery. He remained there 14 months and had three distinct attacks of dysentery and several of malarial fever. He had not previously had blackwater fever. Last October he had a bad attack of fever on his way to England. He had never quite recovered from the dysentery.

On Nov. 25th, 1898, he went to Aldershot to mess and became chilled. Next morning he felt very shivery, came home, and went to bed. I saw him for the first time at 11.30 A.M. on Nov. 27th when he had just had a severe rigor. He was then in the hot stage. His temperature was 104° F. He was jaundiced and had been vomiting. His urine was like porter when viewed in bulk. In the evening I saw the patient in consultation with Lieutenant-Colonel A. Clarke, R.A.M.C. His temperature was then beginning to fall. His urine was claret-coloured. Neither the spleen nor the liver was enlarged and he had no pain in the loins. I should mention here that on Nov. 26th the patient took no quinine and on the morning of the 27th just before I saw him he took a five-grain tabloid of sulphate of quinine and immediately rejected it. On the 28th he was vomiting green fluid almost incessantly. At noon he had a slight rigor. His temperature was 104·2°. The urine was red by transmitted light, had an acid reaction, and contained albumin. Under the microscope no blood corpuscles could be seen. Early on the morning of the 29th I saw the patient in consultation with Mr. W. H. Crosse, late Principal Medical Officer Royal Niger Company. We took some blood-slides and on examination at Guy's Hospital by Mr. Crosse and Mr. Pakes hæmatozoa were found to be present. The patient passed a small quantity of slightly smoky urine which was loaded with albumin. The dysentery still continued; on this day the motions were 10 in number, liquid, dark, mixed with slime and blood;

and horribly offensive. In the evening the headache was less and the jaundice was less marked. The nausea and vomiting, however, were most distressing and the vomit was still bright green. From Nov. 30th to Dec. 4th there was no hyperpyrexia and the fever seemed to be taking on a quotidian type, falling to normal or below it every day and rising to about 99·4°. During this time the patient seemed better, took his nourishment, and slept well. The jaundice was less but he was very anæmic. The vomiting ceased and the dysentery abated a little, the motions being partly formed for some days. The urine remained clear and there was no albumin. On the evening of Dec. 4th, however, his temperature began to run up again and by 4 P.M. on Dec. 5th it had reached 103°. His urine became claret-coloured again, was albuminous, and had a specific gravity of 1012. Under the microscope, according to the report of the Clinical Research Association, "the deposit was seen to consist of a brownish granular débris, apparently the result of the disintegration of blood discs. Hyaline, granular, and epithelial tube-casts were present, but not in any quantity. Leucocytes were not markedly increased in number. Some crystals of uric acid were present. No torulæ were found." By the evening his urine was clearing again and was only slightly albuminous. On Dec. 6th the urine was of the colour of brown sherry. Blood from the peripheral circulation on being examined by Mr. Crosse was found to contain no parasites but nucleated red cells. On Dec. 8th the patient was much worse. His temperature went up to 104° and his pulse to 112. There was no hæmoglobinuria. There was no sign of any lung complication or hepatic abscess. The spleen could just be felt. On Dec. 9th he suddenly fainted and became pulseless while lying quietly in bed; he soon rallied, however, after administration of some stimulant. He vomited twice. His temperature, which was 93·8° in the morning, rose to 102° in the course of the day. Between Dec. 9th and 12th the fever seemed to take on a more remittent type, as it never dropped lower than 99·4° and there was a daily rise of a degree or more. The patient's colour improved and his lips were not so white. There was no action of the bowels on Dec. 10th and 11th. On the 12th there was one motion of the consistency of a poultice, dark brown, without blood or slime, still somewhat offensive. The urine was now averaging about 50 ounces a day and there was no albumin. On the 16th his temperature fell to below normal for the first time. He got up on the 22nd. The temperature fluctuated somewhat until Jan. 7th, 1899, when the maximum was 98·6°. On Jan. 14th he went out of doors.

The treatment for the first 10 days was sulphate of quinine by the mouth in doses varying according to the amount of pyrexia present. He also had a few doses of bicarbonate of soda which relieved the nausea considerably. For the tenesmus I found starch and opium enemata very successful. On the eleventh day I stopped the sulphate of quinine and gave him 18 grains of the bi-hydrochlorate of quinine hypodermically every day, gradually reducing the doses until Dec. 16th, when I stopped quinine altogether and substituted for it iron jelloids (Warwick). At a later stage I prescribed salol in 10-grain doses and the character of the motions was greatly improved thereby, becoming normal in appearance again by the middle of January.

The chief points of interest appear to me to be: (1) that the patient was debilitated by dysentery and by previous attacks of malarial fever; (2) that he had never had blackwater fever before; and (3) that he had had no quinine just before the onset of hæmoglobinuria. I believe this to be the only case on record in which a person has had his first attack of blackwater fever in England. Another point is that there was at no time any tendency to suppression of urine. The course of his temperature showed the fact mentioned by most writers that in blackwater fever the temperature follows an erratic course and that one form of fever tends to merge into another.

Camberley, Surrey.

DEATH OF A CENTENARIAN.—A man named Kohn, said to be the oldest man in Vienna, died there on Feb. 28th, at the age of 112 years, according to a certificate signed by the public notary and by the secretary of the Jewish community of Fraunkirchen, in the county of Wieselburg, in Hungary. He enjoyed talking of his reminiscences of the Napoleonic wars in Austria-Hungary. He married a second time when he was 67 years of age and went to Vienna

NOTES ON A CASE OF DIVERTICULUM OF THE BLADDER.

BY G. A. WRIGHT, F.R.C.S. ENG.,

AND

WILLIAM COATES, M.R.C.S. ENG.

THE patient, a man, aged 38 years, was first seen by Mr. Coates on Oct. 28th, 1898. The patient was complaining of a constant desire to pass urine, of pain in the lower part of the abdomen, of headache, and of feverishness. He stated that in early life he had had three attacks of gonorrhœa and also syphilis. 11 years ago he had painful micturition and his medical attendant advised him to pass a catheter regularly. This he had done ever since, at first twice daily but with increasing frequency until now he passed his catheter twice every hour. He used a No. 12 Jaques. It was never cleansed or disinfected and only rarely lubricated; it was carried in his pocket wherever he went. During the course of these 11 years he had several attacks of hæmorrhagic cystitis but he had never been in bed for more than 10 days. He habitually took considerable quantities of alcohol. When seen the patient was very ill; the temperature was 102° F. and the pulse was 116, small and weak. He had a constant desire to urinate and the urine was very foul, hæmorrhagic, and muco-purulent. The tongue was coated. On abdominal examination a swelling was noticed in the region of the bladder reaching midway between the umbilicus and the pubes. It was irregular in outline, hard, and prolonged on the left side into the inguinal region. It was less marked on the right side. On passing a Jaques catheter about two ounces of urine were drawn off, and on withdrawing the catheter half an inch a further half-ounce came away. The withdrawal of urine made no appreciable difference in the abdominal swelling. A sound passed into the bladder could not be moved freely; no stone was felt. The patient's condition improved slightly after the use of drugs and antiseptics and washing out the bladder, but after two days' treatment he was still so weak and ill that the question of operation became imminent.[1]

On Oct. 31st the man looked very ill; his temperature was about 99·8° and his pulse was quick and feeble. He was tremulous and he had a constant desire to pass urine. His urine was not then very foul. The local condition has been described above. There was nothing abnormal felt per rectum. On passing a large sound into the bladder it could not be depressed, though no obstruction to its entry into the bladder was felt. We thought that possibly the case was one of extravasation around the bladder from the giving way of its inflamed and softened walls, possibly a perivesical inflammation or perhaps a case of diverticulum, the latter view being supported by the results of catheterism. In any case a suprapubic operation was advised. This was declined at the time, but it was agreed to on Nov. 3rd when the man's condition was much worse; he had great pain and hiccough, though his pulse was better. On cutting down upon the bladder above the pubes it was found so hard and thick that it was with difficulty that a knife was pushed into it. On passing a finger into the cavity a diverticulum was found on the right side of about four times the size of the bladder. The bladder itself was pushed away to the left and was only made out by examination with a sound passed through the urethra. The diverticulum lay behind and to the right. A rubber drainage-tube was passed into the diverticulum and it was washed out. The man lingered for a few days and died. At the necropsy the kidneys were found to be suppurating. There was no obstruction to the urethra. The diverticulum opened into the bladder near the orifice of the right ureter.

We have thought this case worth recording as an example of diverticulum of the bladder occurring without any obvious cause of obstruction to the escape of urine. It appears to exactly correspond with the case recorded by Sir John Erichsen. In the present instance the chronically inflamed and constantly irritated bladder seems to have undergone the changes which might be expected to occur as a result of mechanical obstruction and a weak spot in the bladder wall yielded and formed the sacculus. It is an interesting and rare result of misuse of a catheter.

ST. PANCRAS INFIRMARY, HIGHGATE.

A CASE OF DISPLACED OVARIAN CYST WITH TORSION AND HÆMATOMA OF THE PEDICLE.

(*Under the care of Dr. J. SMEDLEY BODEN.*)

IT is remarkable that the cyst of the ovary in the following case had not interfered in any way with the three confinements which took place after its presence had been diagnosed. The enlarged uterus had evidently excluded it from the cavity of the pelvis, for when an ovarian cyst of moderate size complicates a pregnancy danger chiefly arises from the cyst becoming impacted in the pelvis and so interfering with the entry of the head. With a large cyst the danger is more likely to come from rupture during parturition. The suddenness of the onset in this case was very suggestive of torsion of the pedicle of an ovarian cyst.

The patient was a widow, aged 42 years, who had had six children and one miscarriage; the latter occurred 11 years ago and since then she had had three full-term confinements. 14 years ago she was in the Samaritan Hospital for sickness and abdominal pain and was then told that she had an abdominal tumour. Three years later she was in the Royal Free Hospital where she was examined under an anæsthetic, *the result of which examination, thanks to the courtesy of* the registrar, Dr. Boden is able to give verbatim: "A tumour is felt, smooth on the surface, elastic, elongated transversely, and occupying the posterior cul-de-sac. It can be pushed up and felt by the hand on the abdomen and seems as large as a good-sized fœtal head. There is also a swelling felt in, and a little posterior to, the right broad ligament. There seems to be a slight interval between the two tumours, but they are undoubtedly connected. The uterus is quite small and can be readily felt normally placed." The patient had been under treatment twice since for similar attacks, the last time in 1896, when she vomited a considerable quantity of blood. Menstruation had been regular up till the attack in 1896 in which hæmatemesis occurred; since then it had been scanty and occurred at intervals of several months only.

On April 6th, 1898, Dr. Boden was called to see the patient who, whilst reaching up to sweep the walls of a ward with a long broom, had been suddenly seized with violent pain in the left side of the abdomen which doubled her up and induced early vomiting. On getting her to bed the recti abdominis were found to be tense; the abdomen was generally tender, especially in the right inguinal region, where pressure produced acute pain shooting up into the left loin. Under appropriate treatment the peritonitis subsided and by the end of a week tenderness was confined to a dome-shaped swelling above the middle of Poupart's ligament on the right side. As soon as the localised tenderness allowed this was made out to be a fairly mobile, soft, fluctuating tumour situated behind and to the right side of the uterus and was diagnosed as a cyst of the right ovary.

The patient being desirous of having something radical done she was prepared for operation on April 29th. The operation lasted one hour and a quarter and ether was administered throughout. Dr. Boden exposed the anterior surface of the tumour by a median incision five inches long; on endeavouring to bring the cyst up out of the abdomen adhesions were found between it and the omentum, small intestines, cæcum, and vermiform appendix; these appeared to be recent and were all separated by careful sponging, no ligatures being required. On reaching the pedicle and separating its adhesions it was found to be twisted so that two complete rotations of the cyst were necessary to straighten it, and between its layers was found a swelling of the size of a bantam's egg containing tarry fluid. The pedicle was transfixed on the uterine side of the hæmatoma and ligatured and the cyst was removed. In now passing the hand down into the pelvis to ascertain the condition of the other ovary the stump already made was felt attached to the left side of the uterus. The right ovary was then found normally placed and was removed as it showed cystic change. In spite of the many adhesions the peritoneum was fairly dry by the end of the operation so that no drainage was considered essential. The abdominal walls were sutured in layers with silk. The tumour was a multilocular cyst with two main loculi, giving it the shape of a cottage-loaf; the smaller of the two dipped into the pelvis behind the uterus. Its weight untapped was just over two pounds. The after-history was satisfactorily uneventful and the patient has now for some time resumed her duties as ward scrubber.

Remarks by DR. BODEN.—This case seems to be worthy of reporting not only on account of the unusual condition of the parts found at the operation but more especially from the fact that the patient, who had had an ovarian cyst certainly since 1886 when she was in the Royal Free Hospital, had nevertheless been four times pregnant subsequently to that date. She had a miscarriage in 1886. Three full-term children were born since, one in 1887, one in 1889, and the last in 1890. I have been unable to obtain any record of the actual confinements. She was attended from a hospital maternity and as no record of the case was made the existence of the cyst was probably overlooked. The patient herself states that there was nothing unusual about her last confinements except that she had rather longer times with her last three than with her earlier children. The cause of the last attack of peritonitis would appear to have been the rupture of a vessel within the pedicle of the cyst. I must in conclusion express my indebtedness to my colleagues Dr. Chilcott and Mr. Chatterton—the former for his assistance at the operation and the latter for administering the anæsthetic.

PETERBOROUGH INFIRMARY.

A CASE OF SWALLOWING STONES.

(Under the care of Dr. CANE.)

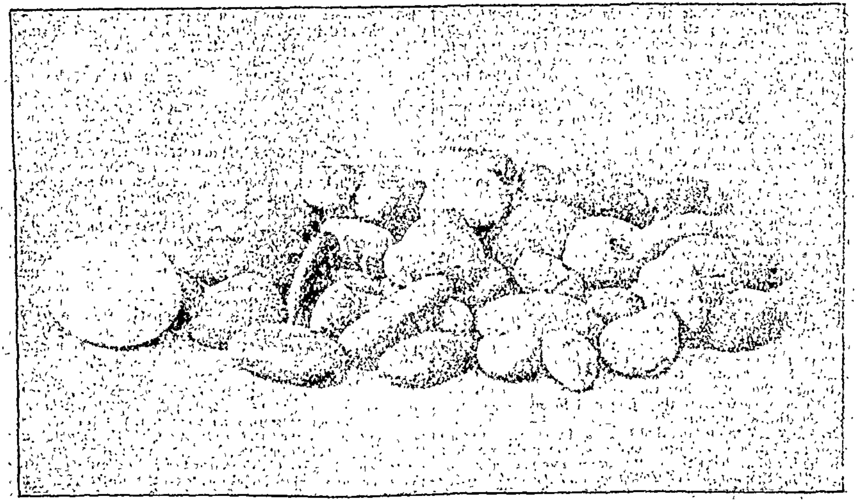
IF a foreign body has been swallowed and has reached the stomach it will in all probability be able to pass unobstructed through the rest of the alimentary canal, and if it should be arrested at any point such arrest is in all probability due to some accidental cause and not merely to the size of the body.[1] In the case reported below the practice of swallowing pebbles had continued for many years without harmful result, but the patient had evidently exercised care in the choice of the stones to be swallowed and it is not improbable that all his symptoms arose from the jagged-edged stone which had to be extracted from the rectum, for sharp points and edges are liable to interfere with the onward passage of the foreign body. We know of no other case in which the practice of swallowing foreign bodies has been carried on for so long a time and with so much impunity. For the notes of the case we are indebted to Mr. Vernon C. Bensley, house surgeon.

A man, aged 32 years, tall and powerfully built, was admitted into the Peterborough Infirmary on Feb. 13th, 1899, at 11.30 P.M., for intestinal obstruction caused by the impaction of pebbles. His history was as follows. When 14 years of age he saw a juggler performing at some country fair. Amongst other items on this man's programme was the swallowing (?) of stones and glass, the latter substance being only chewed. These remarkable feats had such a strong fascination for the lad's brain that he went straight home and swallowed 12 pebbles which he passed per rectum next morning without any ill effects. At his next attempt he managed to swallow 20 stones. In the year 1885 he enlisted and saw active service in Egypt and in the Soudan, taking part in various engagements and receiving a wound of the hand at the battle of Tel-el-Kebir. He remained with the colours for six and a half years, and during this time he occasionally amused his officers and the men with his juggling feats which included the swallowing of stones. After retiring from the army he was placed in the reserve for six years, and during this time he made juggling his sole profession, travelling with Barnum and Bailey's show in the summer and on his own account in the winter. He gave great satisfaction to the show proprietors who offered to take him to America, but this was refused. In this way, he said, he performed in most of the towns of England, Scotland, and Wales. He also took to chewing glass and swallowing the powder, but this he found very distasteful to his teeth and gave it up. The stones which he swallowed during the day he used to pass the next morning or sometimes in the afternoon and always without the slightest pain or discomfort. Occasionally he would have to assist their passage out of the rectum with his finger, but there was never any further difficulty. The number, weight, and size of the stones he swallowed varied very much. He once swallowed, he said, stones to the weight of nine and a half pounds at one performance. On Feb. 10th he gave a performance and as usual passed the stones the next morning, on which day, in the morning, afternoon, and evening, he gave three performances in the market place at Kettering. On the next morning he failed to pass them. The afternoon came and still the stones were not passed, and in the evening he felt paroxysmal collicky pains in the abdomen. On the next day (the 13th) he consulted Dr. W. J. Johnson of Shefford, who very kindly sent a report of his condition at that time, from which Mr. Bensley has taken the following extract:—

---

[1] Maylard: Surgery of the Alimentary Canal, p. 329.

"On Feb. 13th, at 6.30 P.M., the patient was in a common lodging house, sitting on a low form and, doubled up with pain. He said that he had swallowed some 13 dozen pebbles weighing about five pounds and a half. His bowels had not been open since the 11th although he had had a frequent desire to defecate, but without effect with the exception of passing 'blood and slime' and six pebbles. On examining his abdomen there was found a large tumour in the right iliac fossa causing bulging of the abdominal wall in this region and quite perceptible to the eye. The pebbles could be felt and the fingers could be got between them, and crepitus was felt. His pulse was rapid (about 100) and small and his temperature was 99·8° F. He had taken one ounce of castor oil about two hours previously. At 9.30 P.M. he was in much the same condition, but his pulse was more rapid and was smaller and his temperature was 100·8°. He had removed six more pebbles from his rectum and there were no more within reach of his finger. Considering his bad hygienic surroundings it was thought to be advisable to send him to the Peterborough Infirmary. Before he started for the infirmary he was given 20 minims of tincture of opium and one ounce of brandy."



The contents of the rectum photographed. To the left is seen a pigeon's egg by which the size of the stones can be estimated. The reduction in size is a little over one-third.

The patient arrived at the Peterborough Infirmary at

pain. There had been no vomiting, but he was rather collapsed. His pulse was 108 and his temperature was 99·8°. On examining the abdomen there were evident distension of the large bowel and diffuse tenderness, most marked in the right iliac fossa. No tumour could be felt. Mr. Bensley found in the rectum, closely packed together, a number of pebbles, and at once proceeded to extract them with the finger, that being the most harmless instrument in his possession. The extraction of the first five or six was difficult owing to the contraction of the sphincter ani, but when this relaxed their extraction was accelerated. These manipulations were carried out without an anæsthetic and caused some pain, but this was found to be due to the fact that one stone had a jagged edge and after it was extracted there was no more pain. A good deal of flatus was at the same time expelled. There were two stones which could only just be touched with the tips of the fingers and these were brought down with the aid of a scoop. In all 66 stones were extracted; an operation which gave the patient great relief and he passed a good night and next morning he passed six more stones. On the evening of the same day 12 more stones were extracted and on the following morning he again passed seven, making 91 stones in all, which weighed exactly two pounds. The man was discharged from the infirmary on the 18th quite well. He earnestly promised that he would never swallow another stone.

Remarks by MR. BENSLEY.—The above case is, I think, of great interest in that it shows the remarkable tolerance of the walls of the human alimentary canal to foreign bodies. The stones vary much in size, the largest being one and a half inches in length, one inch in breadth, and half an inch in thickness. They have all with one exception rounded edges and it would appear that much time must have been spent in their selection. They are well shown in the accompanying illustration, on the left of which will be seen a pigeon's egg which was placed there in order to display the relative sizes of the stones. The only similar case I know of is the habit which the South African native labourers in the diamond mines have of swallowing diamonds. It is said that thousands of pounds worth of diamonds are annually recovered with the aid of castor oil. I regret that a Roentgen ray photograph could not be obtained. In conclusion, I have to thank Dr. W. J. Johnson for his report of the case and also Mr. A. C. Taylor, the secretary to the Peterborough

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Myelopathic Albumosuria.

A MEETING of this society was held on March 14th, Mr. **THOMAS BRYANT**, the President, being in the chair.

Dr. T. R. **BRADSHAW** and Dr. W. B. **WARRINGTON** contributed a paper on the Morbid Anatomy and Pathology of Dr. Bradshaw's case of Myelopathic Albumosuria. An account of the clinical features of this case was read by Dr. Bradshaw before the Royal Medical and Chirurgical Society in April, 1898, while the patient was alive. Large quantities of albumose were present in the urine for more than a year and some months before death indications of softening and fragility of the ribs, sternum, and vertebræ appeared. The diagnosis made was multiple myeloma—a condition which had been found at the necropsy of patients in former cases of albumosuria but which had never been recognised during their lifetime. Death took place in August, 1898, and the diagnosis was confirmed by the post-mortem examination. The affected bones were brittle, their deeper parts being occupied by a soft round-celled mass and the osseous tissue reduced to a mere shell. Their form, however, was not altered and there were no tumours anywhere. The new growth was submitted to a careful microscopical examination, the results of which were given *in extenso* in the paper. The kidneys were the seat of chronic interstitial nephritis of a moderate degree. The clinical history and the morbid anatomy differed materially from osteo-malacia but corresponded with the description of former cases of multiple myeloma. Only six well-attested cases of albumosuria with bone disease had been published when Dr. Bradshaw read his first paper on the present case. In some of them the bone disease had been altogether overlooked during life, and in the others it had been considered to be osteo-malacia. The present was the first case of albumosuria in which the diagnosis of multiple myeloma had been made and confirmed at the necropsy. Dr. Bradshaw and Dr. Warrington reviewed the six previous cases and pointed out their general similarity to the present one. They laid special stress on the importance of the remarkable reactions of the urine in these cases, and expressed their opinion that the cases of multiple myeloma with albumosuria were of an entirely different nature from those in which albumose does not occur in the urine. For cases of albumosuria with new formations in the marrow they proposed to adopt the term "myelopathic albumosuria."

Dr. **PARKES WEBER** said that in its main features the case described in the paper corresponded with one which he had published under the title of "General Lymphomatosis of Bones" in the *Journal of Pathology and Bacteriology* for January, 1898. In both cases the patients were old men with increasing kyphosis, with severe pains in the bones and progressive debility. Pneumonia was present at the time of death in his and in other published cases and Dr. Bradshaw's patient suffered from pneumonia in the course of the disease but recovered from it. In Dr. Parkes Weber's case nothing abnormal was noticed in the urine when the patient first came under observation, but unfortunately no subsequent observations were made. Possibly, however, albumose might have been present before death, as in a case observed by Senator albumose only made its appearance late in the course of the disease. In Dr. Weber's case there were deposits of calcium phosphate in the kidney, probably not associated with the bone tumours but with the presence of a small adenoma of the kidney. Although it was most easy to account for the presence of albumosuria by supposing that the albumose was formed in the new growth it was difficult to see why albumosuria did not occur in association with lymphomatous growths in other organs of the body.

Dr. A. T. H. **WATERS** (Liverpool) said that he had seen the patient during life. Such cases must be very rare as he had never come across any other in either private or hospital practice. It was possible that they did occur and were overlooked. Now that attention had been drawn to them and that observers had such a careful description to guide them as that given by Dr. Bradshaw and Dr. Warrington probably they would be more often met with. Cases were most likely to come under the observation of the surgeon or to be found in the infirmaries. It was most important to determine whether the presence of albumose was to be regarded as indicative of a certain specific disease.

Dr. **BRADSHAW**, in reply, said that out of 16 cases of multiple myoma on record albumose was only detected in six. Round-celled growths in other parts of the body did not cause albumosuria and they might occur in bones without albumosuria, and he thought that the change in bones which caused albumosuria in the six cases in which it had been found was something *sui generis*.

MEDICAL SOCIETY OF LONDON.

Radical Operation for Inguinal Hernia.

A MEETING of this society was held on March 13th, Mr. **EDMUND OWEN**, President, being in the chair.

Mr. **JOHN LANGTON** read a paper on the Radical Operation for Inguinal Hernia and afterwards traced the history and progress of the surgical treatment of inguinal hernia from the earliest times, observing that surgeons even in comparatively modern times had not viewed with favour operation for the cure of hernia. Up to 1835 no attempt was made to occlude the canal and it was not until Mr. John Wood introduced his improved operation in 1857 that any great success was attained. Mr. Wood claimed 70 per cent. as successes, but Dr. Cheever of Boston stated in 1870 that in America the statistics showed that barely 25 per cent. were permanently cured and reported 20 cases of operation with two deaths. Mr. Langton described four methods of procedure which appeared to involve definite principles as distinct from mere modifications of detail: (1) reconstruction of the inguinal canal with transplantation of the vas deferens and its vessels to the upper angle of the incision so as to form a new inner ring; (2) operations in which the whole or part of the sac was utilised to form a pad or buffer within, or close to, the inner ring so that the peritoneal fossa usually met with is converted into a convex buffer; (3) ligature of the sac close to the inner ring, its excision, and the reconstruction of the inguinal canal; and (4) partial removal of the sac, its ligation and torsion, its withdrawal through the conjoined tendon and the inner pillar of the external abdominal ring, and its retention in this situation by suture. He remarked that it was impossible to determine the exact method to be adopted until the parts were exposed and the conditions were thoroughly examined. He himself preferred and practised whenever possible the operation first described with certain modifications. He described this operation in detail. Kangaroo tendon was used as a continuous rather than as an interrupted suture, the coaptation of the canal being thereby made more complete. Drainage was needed only when hæmorrhage had been profuse or when a cavity was left after removal of a large hernia. In males between 10 and 15 years of age, especially when omentum presented, Mr. Langton's practice was to drag down a considerable piece, returning it into the peritoneal cavity after securely ligaturing it. Rest and maintenance of the recumbent position for a month were most important elements in the after-treatment. Passing on to discuss the question of suppuration he commented upon the widely divergent remarks recorded by various operators in this respect. At St. Bartholomew's Hospital the proportion of suppurative cases amounted to 16·5 per cent. One of the main causes of this, he suggested, was insufficient cleansing of the skin prior to operation. Most surgeons would agree that this complication tended to lessen the full benefit of the operation, though there were surgeons who held the opposite opinion. With respect of the mortality of the operation the danger had been rendered practically *nil*. At St. Bartholomew's Hospital during the six years ending 1898 there were only two deaths in about 650 cases of reducible hernia, one from septic pneumonia and one from scarlet fever. Of 48 cases of irreducible inguinal epiplocele operated on two died, neither death being directly due to the operation. The mortality had greatly improved since 1880. Owing to the high mortality in infants and in extreme old age operations should not be performed at the extremes of life except for pressing reasons. Mr. Langton discussed the various substances used for sutures, he himself preferring kangaroo tendon, and he had not had a single nstance of suppuration. When this did occur the formation of pus was comparatively slight and did not end in he suture coming bodily away as with silk. During he last five months he had performed 30 operations for the cure of hernia; 27 of these had healed by first ntention, while in three superficial suppuration occurred. The hospital records showed that operation for inguinal hernia was performed much more frequently in males than in females. As a possible explanation he mentioned that, according to the tables of the City of London Truss Society, out of 10,770 patients applying for trusses 9900 were males and only 870 were females. Moreover, there were other reasons for more frequent operations in males, such as entrance into public services, their more laborious work, and the constant risk of strangulation. The curative operation was one adapted for girls, in whom it was more simple than in males. Referring to the advisability of a truss after the operation he observed that no part of the treatment excited greater divergence of opinion than that. He himself always advised the use for a time of a supporting instrument, an opinion which was confirmed by experience, seeing that patients who applied for relief at the Truss Society owing to failure of the operation were those who had not worn any support. Of 138 cases 78 were advised not to wear a truss, while 60 were recommended to wear one for a limited period. In private practice he always recommended a truss. The operation was contra-indicated—(1) when the age was less than six years; (2) when there was co-existent organic disease; (3) when the hernia was so large that the abdominal cavity was unable to receive or retain under moderate pressure the extruded viscera (in such cases a palliative operation to retain the hernia aided by a truss might secure the patient from the chance of strangulation); (4) when the patients were very old; (5) when the tendino-muscular walls were weak and bulged for a considerable area on coughing; and (6) when septic peritonitis the result of strangulated hernia was present. Mr. Langton called attention to the almost insurmountable difficulties in the way of obtaining an estimate of the permanent results of the operation. Two years was the shortest period within which an opinion could be expressed. Statistics gave most conflicting results. The records of the City of London Truss Society showed that in the last six years 242 patients upon whom operations had been performed were treated for failure of the operation, from which it might be inferred that the total number of failures must be very considerable. In private practice the results were better known and were encouraging, 80 per cent. being successful at any rate for several years.

The PRESIDENT objected to the use of the term "radical cure," he himself always calling it the "operation for the radical cure." He often operated on children under six years of age and asked the Mr. Langton whether he would rigidly adhere to that limit under particular circumstances, as, for instance, in a child, aged three years with careless parents and hernia steadily increasing in size. For suturing he preferred a material which could be used for everything, such as silk, which, in his experience, did very well.

Mr. STANLEY BOYD observed that it would be very useful if surgeons could learn the ultimate results of their operations. He insisted on the importance of leaving the peritoneum smooth and tense, a point about which he was always very careful. He always applied torsion to the sac, but in one case the bladder was unfortunately included, with a fatal result. The next important structure was the transversalis fascia which should be closed by a continuous suture. He urged that the muscular arch should be restored as far as possible to the normal arrangement, thus materially assisting in preventing relapse. He used a fishing gut stitch to close the external oblique, removing any superfluous fat. For the last two years or more he had always operated by a flap, putting three knots on the fishgut suture, which was a continuous one, cutting off the ends close to the knot. Since he had done this he had not had an instance of a stitch reappearing on the surface. He agreed with Mr. Langton as to removing a piece of omentum. He confessed to having had some cases of suppuration and observed that there was no operation in which suppuration gave so much trouble. He thought the best plan was to give an anæsthetic and to take out some of the external stitches, passing through the internal oblique and transversalis and placing a tube in contact with the neck of the sac. He observed that it would be interesting to discuss the causes which underlay the greater frequency of femoral hernia in the female after puberty, especially as the sexual differences in the pelvis were as marked in a five months' fœtus as they were afterwards. He himself had fixed three years as the limit of age for operation in infants, that being the age at which children had acquired control over the bladder. Personally, he never recommended a patient to wear a truss unless the abdominal structures were unusually weak.

Mr. OSBORN asked Mr. Langton how long he thought patient ought to wear a truss after operation, a practice of which he approved, though patients were often disappointed, having looked forward to being enabled to dispense with its use after the operation. In young children a hernia would often disappear with a truss without any operation.

Mr. LANGTON, in reply, congratulated the President on the fact that his name did not appear on his list of London surgeons responsible for the failures to which he had alluded. In praising kangaroo tendon he did not wish to decry silk and fishing gut. He did not wish to lay down any hard-and-fast age limit. In his paper he had stipulated that if the child were well cared for he would not advise an operation. His experience at the Truss Society was that in most instances when a truss was applied to a child the rupture was not heard of again. He agreed that the limit of three years was not a bad one on the whole. He concurred in the importance of leaving the peritoneum tense and smooth. The inclusion of the bladder when torsion was applied to the sac was an accident which might happen to anyone, but he always opened the sac and passed his finger into the peritoneal cavity before applying torsion. (Mr. BOYD remarked that this was his invariable practice also.) Mr. Langton confirmed the remarks which had fallen from Mr. Boyd on the vital importance of arching over the fibres of the internal and oblique transversalis. In private practice he often ordered gymnastic exercises with the object of increasing the musculature and tension of the abdominal walls. He pointed out that femoral hernia occurred principally in women between puberty and the menopause, so that the influence of parturition was probably a factor in its production, though even during this period hernia in a pregnant woman was inguinal in 99 per cent. of the cases.

CLINICAL SOCIETY OF LONDON.

Hydatid Cysts in the Lung and the Liver removed by Operation.—Pancreatic Cyst treated by Drainage.—Removal of Malignant Tumour involving the Frontal Bone.—Erasion of the Ankle-joint.

A MEETING of this society was held on March 10th, the President, Mr. LANGTON, being in the chair.

Mr. H. BETHAM ROBINSON described a case of Hydatid Cysts in the Upper Lobe of the Right Lung and in the Liver both successfully removed. The patient was a boy, aged six years, who was admitted under his care into St. Thomas's Hospital on June 7th, 1898. There was nothing to note in the previous history except that for some time he had had a cough. When first noticed, three years before, the abdominal tumour was of the size of a marble and had gradually become larger without any pain. Up to his admission there had been no suspicion of the existence of a cyst in the lung. On examination he was found to have a firm rounded cystic swelling in the right hypochondriac and lumbar regions, reaching almost to the middle line and to the level of the umbilicus below. There was a rounded nodular projection on its inner side just under the umbilicus. The liver dulness began at the seventh rib in the nipple line and was continued down over the tumour. The whole swelling moved with respiration and it could be grasped between the hands placed in front and behind. The urine was slightly albuminous. The chest on examination showed that the upper part of the right side in front bulged. The percussion note was dull down to the third rib and dulness was also present high in the axilla and over the apex of the lung posteriorly. Over the dull area in front the breathing was tubular and vocal resonance increased, but behind all sounds were diminished. No crepitations were elicited on coughing. There was no elevation of temperature, so the physical signs were suggestive of a hydatid in the lung. On June 22nd the liver hydatid was operated on by an incision in the linea semilunaris. The liver came well below the costal margin and a cyst was seen springing from the inferior surface having the [illegible] on its upper surface malt and other alcoholic liquors. The merit of this work is that it does not deal with a difficult subject ponderously but in a way that should be clear and intelligible to the class of reader—namely, the medical student—for whom it is primarily intended.

Text-book of Medical and Pharmaceutical Chemistry. By ELIAS H. BARTLEY, B.S., M.D., Ph.G., Professor of Chemistry and Toxicology in Long Island College Hospital. Fifth edition. Revised and enlarged. London: H. Kimpton. 1899. Pp. 738.

IT is not easy to write for the benefit of the student of medicine a text-book within the bulk of that before us which will embrace not only pure chemistry but also physics, physiology, and pathology so far as these refer to chemistry in accordance with the requirements of his study. Yet the author has succeeded in stocking his book with most of the information of the kind indicated in a volume which is certainly not beyond the dimensions of a companion or manual. The first edition was published in 1885 and the present is the fifth edition, so that in a little over 12 years five issues have been demanded. This of course is evidence of the esteem in which the book is held. It is written essentially for medical students in the States during their attendance upon lectures. This in no way detracts from its use as a lecture companion in this country, as well as a book of reference. The author is evidently fully aware of the necessity of making the student feel how important a knowledge of chemistry is in connexion with medical study. He does not burden the reader with a host of irrelevant facts, but, on the other hand, amplifies those points in chemical structure and composition which border on chemistry and physiology and which will be found a help to clinical study. The work is divided into five parts, Part I. dealing with Chemical Physics, Heat, Light, and Electricity; Part II. with Theoretical Chemistry (the mathematics of the science); Part III. with Inorganic Chemistry; Part IV. with Organic Chemistry; and Part V. with Physiological and Clinical Chemistry. Quite apart from other sections the last might form a separate handbook on practical pathology and physiological chemistry since it is so serviceably and suitably treated. The official names of medicinal chemicals are given according to both the United States and the British Pharmacopœias. On the question of nomenclature the author has not employed the abbreviated method suggested by the American Association for the Advancement of Science. He adds, however, an appendix embodying the rules drawn up so that students may become acquainted with the proposed changes. We have found one or two trifling misprints in the book, as, for instance, HCl_2 on page 111 and "celluloes" for cellulose on page 607. The analytical processes described are good, but the author appears to ignore what is acknowledged to be the best method, as it is the most scientific, for the estimation of uric acid in urine—namely, that devised by Hopkins. In this process the uric acid is precipitated as acid ammonium salt with ammonium chloride, the pure salt so separated being titrated with standard permanganate in the presence of diluted sulphuric acid. The plan of the book in regard to the order in which the facts and theories of chemical science should be presented to students—namely, theory first and facts afterwards—is one which we are rather inclined to approve. The author has found space for a short description of the newly discovered elements, argon and helion. The style is clear and intelligible. As we have already indicated the author has dealt dexterously with a mass of facts retaining as far as possible only that important portion of the science which is of direct concern to the medical student. The requirements of the medical student are fully understood, which is not surprising since Dr. Bartley has had experience as a teacher in Long Island Hospital for a number of years.

---

1. *Mad Humanity, its Forms, Apparent and Obscure.* By L. FORBES WINSLOW, M.B. Cantab., D.C.L. Oxon. London: C. A. Pearson, Limited. 1898. Pp. 450. Price 7*s*. 6*d*.
2. *Primer of Psychology and Mental Disease.* By C. B. BURR, M.D. Second Revised Edition. For Use in Training-schools for Attendants and Nurses. Philadelphia: F. A. Davies Company. 1898. Pp. 116. Price 2*s*.
3. *The Story of the Mind.* By Professor JAMES MARK BALDWIN. London: Geo. Newnes, Limited. Pp. 260. 1899. Price 1*s*.

THE above works are all popularly written for the information of general readers or for nurses and attendants on the insane, or for students commencing psychology. The first work portrays some of the commoner and more superficial appearances and symptoms of prevailing types of insanity with the aid of photographs of lunatics. Dr. Winslow believes that the increase of insanity in the past decade, as shown in official lunacy returns, must be real rather than apparent. Increased alcoholic intemperance is given the first place in the causation of mental disease. A sketchy account of "madhouses" and their past history and of the present condition of lunacy opens the work; curiously enough no account is given of the philanthropic work of Pinel in France or Tuke in England, who were pioneers in the "humane" movement of lunacy reform. The writer thinks that "in order to become a useful *physician* it is necessary to become a good *metaphysician*," and plentifully is the text mingled with discursive matter and digressions illustrative of this attitude; and then the author invokes poetry to his aid. There is much "padding" of this sort throughout the book. Sensational accounts are given of "strange lunacy cases" and of the "madness of genius." These are scarcely satisfactory from the critical and scientific standpoints. As examples of the "madness of genius" there are mentioned Samuel Johnson, Schiller ("love made Schiller mad" is the writer's dictum), Robert Burns (an example of dipsomania and melancholia), Shelley (a case of demonomania), &c. Even the Wizard of the North is not spared: the vigorous sane genius of the "Waverley Novels" and "Marmion" is made to illustrate this madness of genius in company with Shakespeare; and after moralising and poetising on the "mental degeneration of the human race" the book concludes with a characteristic poetical quotation from Bryant. The work cannot be commended to the physician, the alienist, or the general reader.

Dr. Burr's Primer has reached a second edition within four years. It gives an outline of psychology (27 pages), followed by brief and simple descriptions of the ordinary types of insanity (33 pages) such as come under the observation of asylum nurses and attendants. Then follows a concise but practical account of management of cases, under the headings of Feeding, Nursing and Personal Attendance; Exercise, Employment and Diversion; Sleep and Rest; Faulty Habits; Mechanical Restraint; and Guarding against Suicidal and Violent Impulses; with homely and good advice on these points. Some general suggestions and a useful index conclude this little work which may be recommended to nurses and attendants in public and private asylums.

Professor Baldwin's work is conceived in a true scientific spirit and is cast in a good mould. The "Story of the Mind" in its manifestations in the adult, but especially in the young, is well told. The author is well known for his valuable contributions to psychology in the special direction of "Mental Development in the Child and the Race." The scope of the work is, for a primer, ambitious. Under such headings as the Mind of the Animal, the Mind of the Child, &c., charming accounts and descriptions are given which while popular are also accurate and suggestive. Chapter V., on Child Psychology, may be read with profit and pleasure even by our psychologists and neurologists. Simple experiments in psychological time-measurement are given. The short chapters devoted to education and suggestion (including hypnotic conditions) in children and adults and the training of the mind in childhood may also furnish valuable *hints to teachers in our elementary schools.* Professor Baldwin's philosophy is cheery and optimistic; we have seldom read a more thoughtful and suggestive little production. It can be strongly commended to students of psychology, to the general reader, and to all who take an interest in the study, training, and mental upbringing of the young. The low price at which this little work is produced is remarkable and the general get-up of the book is a credit to the publishers.

LIBRARY TABLE.

A Code of Rules for the Prevention of Infectious and Contagious Diseases in Schools. Issued by the Medical Officers of Schools Association. Fourth edition. London: J. & A. Churchill.—We learn from the preface to this useful little book that eight years have elapsed since the publication of the last edition and owing to the many changes which have occurred and advances which have been made in sanitary and medical science the statements in the book have been thoroughly revised. Thus, the quarantine periods allotted to small-pox and scarlet fever have been reduced but special attention is drawn to the fact that disinfection of both the patient and his clothing must be carried out at *the commencement* of the quarantine period. In the case of diphtheria and ophthalmia it is pointed out that only a bacterioscopic examination will in many instances afford opportunity for definite diagnosis.

Bailey's Index to the Times. Published monthly. London: Eyre and Spottiswoode. January and February, 1899. Price 3*s.* per number.—This is one of the best and fullest indices which we have seen, the cross-indexing being particularly good. This point has not been so fully carried out in the February number as in the January issue owing to the necessity for saving space on account of the increased matter due to the meeting of Parliament. But even so the index is quite full enough for all practical purposes.

JOURNALS.

The Quarterly Journal of Microscopical Science. Edited by E. RAY LANKESTER, F.R.S., ADAM SEDGWICK, F.R.S., and W. F. R. WELDON, F.R.S. With 10 Lithographic Plates and Engravings on Wood. London: J and A. Churchill. February, 1899. Price 10*s.*—This part contains only two articles, the first by Arthur Dendy, D.Sc., Professor of Biology of Canterbury College, New Zealand, entitled Outlines of the Development of the Tuatara, Sphenodon (Hatteria) punctata (which occupies nearly the whole of the number), and the other by J. W. Jenkinson, M.A., an Abstract and Review of the Memoir by G. Hieronymus on Chlamydomyxa labyrinthuloides. Dr. Dendy was induced to study the development of the Tuatara by the examination of the parietal eye in some embryo Australian skinks which present an optic cup similar to that of the paired eyes. He has with the coöperation of Mr. Henaghan, the principal keeper on Stephens Island, secured a magnificent series of embryos the majority of which have been hardened in Kleinenberg's picric acid after removal from the egg and preserved in alcohol. The island where the Tuatara is found is densely covered with scrub of various kinds; the soil is good on the ridges and in the gullies it is of a light brown colour, largely composed of oxide of iron. Petrels and the lizards are both very numerous, and occupy the same hole, living together in peace. The breeding season commences in November on Stephens Island and each female lays about 10 eggs. The males are much more frequently met with than the females. Dr. Dendy thinks the eggs take about 12 months to develop and that they are laid in November. We must refer our readers to the original for the details of the development of this lizard. *They are there very completely given and the description is* illustrated by 10 plates with numerous drawings on each.

Archives Générales de Médecine.—This old-established journal now makes its appearance under the form of a new series commencing last January and concurrently with this alteration in the style of issue valuable improvements have been introduced. It is brought out on the 1st of each month in parts containing 128 pages, illustrated with plates and engravings, and forms at the end of the year two volumes of about 800 pages each. The editor is Dr. Émile Boix, 13, Rue des Saussaies, Paris. The publishers are MM. Asselin et Houzeau, 2, Place de l'École de Médecine. The annual subscription for the postal union is 25 francs. The articles in the March number are on Paralytic Vertigo (by Dr. F. Gerlier); on the Influence of the Nervous System in Diseases of the Skin (by Dr. E. Leredde); on Feebly-acting Chronic Localised Infections (by Dr. J. Brault); on a case of General Staphylococcus Infection (by Dr. J. Marty); on Vascular Lesions (by Dr. E. Coulon); and on the Anatomy of the Lung (by Dr. E. Rabaud). According to Dr. Gerlier paralytic vertigo especially attacks shepherds who milk cows and has only been discovered in Switzerland and Eastern France within the last 25 years, but it is endemic in Japan.

Revista Medica de S. Paulo.—In the January number of this Brazilian journal Dr. Adolpho Lutz continues his articles on the Bites and Stings of Various Insects; Dr. Pedro de Almeida Magalhães gives the first part of a paper on *Heart Murmurs in Beri-beri*, with an account of five cases; and Dr. Victor Godinho and Dr. Guilhermo Alvaro write on the Treatment and Prophylaxis of Tuberculosis.

La Grèce Médicale.—In the February number Dr. Timoleon Triantaphyllides of Batoum continues his articles on the Malarial Diathesis in the Caucasus; Dr. N. Saltas of Aivali describes a case of Progressive Pernicious Anæmia cured by subcutaneous injections of citrate of iron (4 c.c. of a 4 per cent. solution every second day for a period of 38 days); Dr. Mantzavinos of Laurium gives details of an incomprehensible case in which a girl, 18 years of age, made an apparently unfounded charge of rape against a man who had previously been requested to marry her and had refused to do so; there was recent laceration of her hymen and on examination a hen's egg was found in the vagina.

Rivista Universale di Medicina, Chirurgia e Scien Affini.—We have received the first two numbers of this new Italian monthly journal which, as its name indicates, makes a special feature of selections from contemporary periodicals. The original articles include a long paper, not yet concluded, by Dr. Enrico D'Anna on the Application of Electricity in Disorders of the Blood-vessels, such as phlebangiectasis, erectile *tumours*, varix, aneurysm, and angioma. The journal is conducted by Professor Vincenzo Morini and Dr. A. Bretschneider, consists of about 60 pages, and is published on the 15th of each month at 11, Via Firenze, Rome.

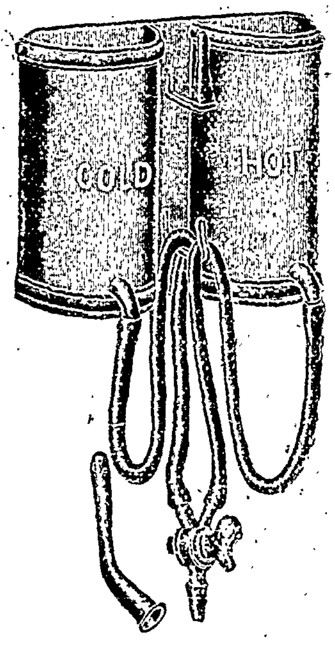
Clinica Ostetrica.—This journal, the first number of which appeared last January, is described in the sub-title as a review of Obstetrics, Gynæcology, and Children's Diseases. It is edited by Professor Felice La Torre of the University of Rome, contains 56 pages, and is published monthly by the firm of I Fratelli Capaccini, Porta Cavalleggeri, Rome. The original articles in the January number are on Tuberculous Peritonitis in Women (Professor F. Durante), on the Suckling of the Infant by its Mother (Dr. F. S. Rocchi), on the Etiology of Disorders of Digestion in the Infant (Professor L. Concatti), and on Insanity in Women during Pregnancy, Childbirth, and Suckling (Dr. B. Vespa).

Mercy and Truth.—In the March number Mr. Jukes contributes a further paper on his work at Dera Ghazi Khan in the Punjaub, together with a plan of the Maxwell Gordon Memorial Hospital. The principal illustration is a portrait of the late Bishop J. S. Hill of West Africa.

New Inventions.

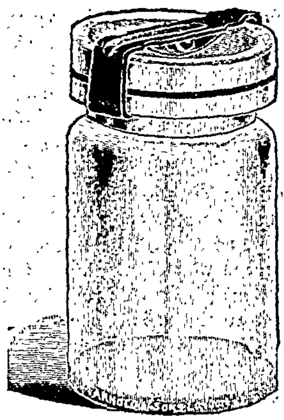
AN ALTERNATING DOUCHE.

VARIOUS contrivances have been suggested for the application of rapidly alternating heat and cold to different parts of the body. An instrument of this kind for the treatment of chronic prostatitis has been introduced by Dr. Scharff of Stettin under the name of the "thermopsychrophor" and it was briefly noticed in THE LANCET of Nov. 12th, 1898 (p. 1305). Another apparatus on a similar principle, devised by Dr. Heinrich Schmidt and intended for use in gynæcology, is represented in the annexed illustration. It consists of two irrigators joined together, one for hot and the other for cold water. To each is attached a long piece of india-rubber tubing, both of which meet in a three-way stopcock. A nozzle fitting on the stopcock is inserted into the vagina, and the hot douche is allowed to run for about half a minute, after which the tap is given a quarter of a turn and the hot is then succeeded by the cold douche, which is continued for a quarter of a minute. This should be done, using the hot and cold douches alternately, four or five times consecutively, and the process repeated several times daily. Of course, the water may be either medicated or not, at the discretion of the practitioner in attendance. Dr. Schmidt recommends that at the outset the temperature of the water should be 86° F. in the one irrigator and 64° in the other. He states that the apparatus may be obtained from any druggists' sundriesman or any dealer in surgical instruments.



THE SAFETY VALVE BOTTLE.

A SPECIMEN of a new pattern of bottle which has been introduced by Messrs. Arnold and Sons of West Smithfield has been sent to us for inspection. The construction of the "Safety Valve Bottle" is quite simple and will be readily understood from the accompanying illustration. The rubber ring which is outside the neck of the bottle is pressed down by the cover and held air-tight by the clamp. The clamp is easily removed by lifting the lever without injuring rubber, cover, or clamp and can be used over and over again. The bottle is made in different sizes and is very suitable for ligatures, sponges, ointments, powders, &c.



KANTHACK MEMORIAL FUND.

THE following is a list of the subscriptions which have been received for the Kanthack Memorial Fund, concerning which we have already written in THE LANCET. Dr. J. H. Drysdale, 25, Welbeck-street, W., is acting as honorary secretary.

THE BRISTOL ROYAL HOSPITAL FOR CHILDREN AND WOMEN.—The thirty-third annual meeting of this institution was held on March 10th under the presidency of the Mayor. The report stated that during 1898 3143 patients had been treated, and of these 636 children and 39 women had been admitted as in-patients. The financial statement showed that the total expenditure, which includes the Convalescent Home in connexion with the hospital at Weston-super-Mare, amounted to £4048. The receipts were £2900. The accumulated deficit of the last four years now amounted to £2771.

THE LANCET.

LONDON: SATURDAY, MARCH 18, 1899.

THE questions raised by the deputation from the Council of the Poor-law Medical Officers' Association recently received by Dr. FARQUHARSON, M.P., afford food for reflection to the framers of statutes, to guardians of the poor, to the medical profession in general, and to the Poor-law medical service in particular. The principal object of the deputation was to draw the attention of the legislature to certain results which have ensued from the operation of the Poor-law Superannuation Act (1896) to the serious detriment of the Poor-law Medical Service. It is sufficiently heart-breaking work to labour amongst the poorest of the poor who need food more than medicine; but if we add to this the lowest of possible salaries and the most critical of masters the lot of the parish medical officer is certainly not an attractive one. As regards the salary, it is fixed at a figure considerably lower than any payment made for similar work and wholly out of proportion to the duties performed or the trouble and responsibility involved in their execution. In many of the eastern districts of London the work engages nearly the whole time of one assistant. It not infrequently happens that for £30 or £40 a year a medical man is required to attend several times a week at some appointed place and be at the beck and call, at all hours of the day and the night, of the relieving officer and the poor. And woe betide the hard-working medical officer who thinks at 9 P.M. perhaps that he will have his dinner before he attends to a summons which might probably have been equally well sent in the morning.

These things may well afford food for reflection to the whole profession, for it is an ominous sign of the times that there is no dearth of candidates for these posts. But if a man be asked why he applies for a position like this he probably says, "As an introduction to practice." Another, if he be asked why he retains a post of this kind replies, "To prevent another medical man from diminishing my meagre livelihood by setting up in the neighbourhood." The guardians are probably not aware of these considerations, but, taking full advantage of them, they adopt a "market value" line of argument and question the need of giving a higher salary when candidates can be procured at a lower one. These gentlemen forget that by supplying really competent medical aid for the poor they shorten the time during which the poor remain on the rates, and that the greatest inducement to really efficient service is to be found in the contented mind of an official satisfied with his lot and his remuneration.

Until lately there was one redeeming feature in the conditions of the Poor-law medical service—namely, the small pension to which a medical practitioner who had been for more than 10 years in the service could look forward in his declining years. It is true that before the enactment of the Poor-law Officers' Superannuation Act this pension was given at the option of the guardians who happened to be in office at the time of his retirement, but the medical officer could generally rely on a just consideration at their hands if his relations with them were fairly amicable. However, it was hoped that the passing of this statute would improve matters in this respect, by giving the medical man a right to a pension which before was optional. The amount to which he is entitled under this statute is based on the length of his service—one sixtieth of his average salary and emoluments for each year of service, whether under the same or a different board of guardians. In order to meet this charge on the rates a certain percentage is deducted compulsorily from each officer's salary at the time when it is paid—usually every quarter.

This statute was very carefully drawn up and its framers were confident of its beneficent effects for all concerned. However, in actual practice it is found to fail in the very direction where it was expected to accomplish most—at least, so far as the district medical officers are concerned—owing to the action of certain boards of guardians. So far is this the case that unless something in the way of amendment of the law is speedily introduced a very grave injustice will be done to a very deserving and already underpaid body of men, and serious harm to the service generally.

As regards the financial basis contemplated by the Act—which it may be remarked in passing applies to all Poor-law officers, medical and non-medical alike—the deductions from all officers' salaries do not go to form a special fund, but are entered in the debtor and creditor account of the parish to which the official belongs, any pensions payable at the time appearing on the other side. It was contemplated that in the long run the one would balance the other. But an officer is entitled to claim as a basis of his pension any years of service previously spent in other parishes, and the guardians with whom an official is serving at the time of his retirement, who thereafter pay the pension, seem to imagine that they are paying a charge which properly belongs to another board At any rate, when the election of a medical officer is in question the guardians in many instances have, it is alleged, taken this question of the possibility of superannuation into consideration in a manner which seems to us to be unjustifiable—a manner which was not contemplated in the framing of the Act, and one which is certainly not conducive to the efficiency of the Poor-law medical service. It is alleged, for instance, that certain boards have selected younger candidates who have not previously held office under the Poor-law and who could not therefore claim such large pensions as those who had had previous service. Now, other things being equal, it is certainly not conducive to the efficiency of the Poor-law to have inexperienced and untried officials. Medical work in connexion with the Poor-law requires considerable experience for its efficient performance. Not that medical science itself is different, but, to mention one aspect alone, the detection of, and dealing with, malingerers, to decide exactly how much of a person's illness is assumed, and precisely what amount of work he or she is fit for, requires not only a skilled [illegible] intelligent, but also problems form part of the daily work of the Poor-law medical officer.

But there is yet another way in which the Superannuation Act seems likely to jeopardise the best interests of the service and to fall most unjustly on the present holders of office, especially in certain rural districts. When a Poor-law medical officer does not reside within his district it is the custom that his appointment shall only be for a limited time—usually one or three years—at the end of which it has hitherto been customary for him to be re-elected as a matter of course. Now, undoubtedly it is more convenient, other things being equal, that the medical officer should reside inside, or within easy access of, his district; but in certain places, especially in country parishes, this is not possible or expedient. A large number of district Poor-law medical officers have held office under these conditions for many years and the arrangement has worked satisfactorily for all concerned. Their re-election each year has been merely a matter of form. But since the introduction of the new statute it has been alleged that in several such instances where a medical man has had a long and blameless record, but where he was approaching the age at which his pension would become due—namely, 60—his re-election has not taken place, and consequently he has lost all chance of his pension. These posts are nearly always held by men settled in practice who cannot, therefore, seek office elsewhere, even if there were a chance of their election, which, as we have just seen, is very slender. The extreme injustice of such a proceeding is obvious. Very often special arrangements have been made by the medical officer and a special assistant has been engaged for the work; moreover, compulsory deductions have been made from the officer's salary in view of the pension to which he would be entitled.

How the most carefully framed statutes may fail in actual practice is a fact well known to legislators. But we venture to think that a greater flaw than this has rarely been revealed. The remedy lies in two directions. In the first place, the deductions from salaries in view of pension from all parishes should go to form a common fund. In this way one parish could not feel that it was paying a pension which really belonged to another. Secondly, the limitation of office to a short period should be abolished. If a medical officer is eligible both in qualification and residence to discharge the duties for one year there seems to be no adequate reason why he should not be eligible to discharge them for a longer time. In general terms a very large proportion of the problems connected with the administration of the Poor-law are of a medical nature, and certainly it is a short-sighted policy which selects as a medical adviser to a board of guardians a young medical man wholly inexperienced in such matters, or which constantly changes such adviser as soon as he is beginning to learn his work. Such a state of matters as we have here depicted is detrimental to the best interests of the Poor-law service and unjust to the individual. It certainly requires the attention of the legislature without delay.

◆

IT is now nearly 10 years since the disease known as "influenza" appeared in epidemic form in this country, after an interval of 43 years. There are difficulties in ascertaining the exact chronological order in which different parts of the country were attacked with the complaint, for although cases were not actually recognised and reported until towards the end of December, 1889, yet subsequent reflection convinced many medical men that they had met with cases considerably anterior to that time. Since that epidemic the community has been rarely, if ever, entirely free from the disease and recrudescences have from time to time occurred, although they have not assumed such proportions as were reached in the early part of 1890. It forms an interesting study, although not a consoling one, to look back over the 10 years in order to ascertain how far medical science has advanced as regards the recognition, treatment, and prophylaxis of the malady.

Dr. SISLEY's book on "Epidemic Influenza" and the able report presented to the Local Government Board on the epidemic of 1889-90 by Dr. H. F. PARSONS give an excellent *résumé* of the information which had been collected up to that time. The fact that this epidemic was the first that had visited this country since the establishment of a central health authority renders such a report particularly interesting. The first point which strikes us is that the type of the disease has undergone constant alterations, and the varieties of symptoms which present themselves are so numerous that it is difficult to recognise them as forming instances of the same disease, the clinical course of which during the epidemic just referred to was so characteristic. Experience has shown that the complications are so diverse that their importance outrides that of the original malady, and indeed they may be even mistaken for it and thus the difficulties of diagnosis may be manifestly increased. Various hypotheses were suggested as to the etiology of epidemic influenza, such as the theory that it was due to climatic conditions or to some "aerial poison" or "miasm"; other observers contended that it was zoogenous in origin—that is to say, derived from "equine influenza," or that it was carried by migratory birds; another suggestion was that the disease had a dietetic origin, being disseminated by means of Russian oats. These theories have, however, one by one been discarded and it is now generally acknowledged that the bacillus discovered by Dr. PFEIFFER in 1892 is the causal factor and, as we have already pointed out,[1] Dr. FINKLER maintains that the presence of this microbe in the sputum should form an essential part of the diagnosis in doubtful cases.

It is frequently difficult to distinguish between a "febrile catarrh" and an attack of influenza; both have many symptoms in common, although the mode of onset and the danger of complications differ considerably. Unless care is taken in the diagnosis needless alarm is often created. If therefore means for the detection of Pfeiffer's bacillus can be easily carried out a valuable help in this respect is at hand. There is an article on this subject in the monthly report (February) from the Department of Health, of the City of Chicago. After quoting from the *Medical Age* to the effect that influenza seems to have a strange attraction for some people, and every febrile catarrh of whatever kind is called "la grippe"—"gastric cases, headaches, sore-throat, coryzas, are all grippe"—the results are given of some experiments carried out by Dr. F. E. WYNEKOOP, First Assistant Bacteriologist of the department. These results only take the form of a "preliminary report," but Dr. WYNEKOOP has demonstrated that after the observer has become familiar with the appearance of the Pfeiffer bacillus under the microscope it may be readily identified in the sputum and mucus of a patient suffering from influenza by direct examination without awaiting the result of cultivation. We have before expressed our opinion on this proposal and trust that further investigation will be made in order to test the clinical value of such bacteriological examinations.

---

[1] THE LANCET, Jan. 14th, 1899, p. 103.

Dr. OSLER, following the opinions of many competent observers, states that the respiratory system is peculiarly likely to be involved, whilst others, although agreeing with this statement, believe that the main force of the disease is expended on the nervous system and much has been written on the "neuro-pathology" of influenza. Dr. GOODHART[2] draws attention to the fact that there is no record in former times of the long series of nerve disorders following influenza with which we are now but too familiar and which will be found by our successors when in the stress of epidemics yet to come they study, as we do to-day, the recorded experience of the past. It is undoubtedly true that influenza has shattered the nervous systems of a large number of its victims, in some cases permanently, in many for several years after it has run its course. These subsequent events may lead to the diagnosis of influenza after the event, the primary attack being so vague that no conclusion could be arrived at until the train of nervous symptoms suggested the true nature of the original disease.

Whilst we may claim to have made considerable advances during the past 10 years in the knowledge of the etiology and pathology of influenza we can show but little improvement in our methods of treatment and prophylaxis. This can cause no surprise, as the disease is probably transmitted in a similar manner to pulmonary tuberculosis through the mucus and secretions derived from the respiratory tract, which Dr. PFEIFFER has shown is the home of the active germ. That being so, prophylactic measures are accompanied by the same difficulties as is the case with regard to "consumption." Most risk is therefore run in ill-ventilated buildings, and although the healthy may be attacked, yet any mode of life which tends to lower the vital powers at the same time renders the individual more prone to infection. Statistics testify to the frequency of the disease and to its heavy mortality, particularly in the alcoholic and also in the over-worked and aged.

As respects treatment no specific has yet been discovered and much the same measures are now adopted as in the epidemic of 1890 and even in earlier outbreaks. In THE LANCET of Jan. 11th, 1890, commenting on the means which might be adopted we said: "The lines originally laid down by Dr. PEACOCK do not appear to have been very materially modified by anything that has since been written, and they resolved themselves mainly into directions for symptomatic treatment. He recommended for the simple form the use of diaphoretics, anodynes, stimulants, and tonics, and although the list of remedies falling into these groups has of late years been largely increased the main principles remain the same." These words hold good of our treatment during the present epidemic; the experience of over nine years, since the above was written, has simply corroborated Dr. PEACOCK's statements. Complications must of course be treated as they arise, but the most difficult to control are probably the form of pneumonia occurring in connexion with influenza, which is usually of a particularly virulent character, and the nervous symptoms, which are also singularly rebellious to all therapeutic measures.

* * *

THE answer given by Mr. CHAPLIN in the House of Commons, in response to a question by Mr. CHANNING on Feb. 9th as to what action the Government intended to take on the recommendations of the Royal Commission on Tuberculosis so as to prevent the sale of milk from tuberculous cows prepared us for the issue of regulations by the Local Government Board under the Dairies, Cowsheds, and Milkshops *Order of 1885. This issue* has been accompanied by a circular of advice and instructions bearing upon the question of the seizure and control of meat of tuberculous animals placed on sale as human food; and a separate order has also been issued declaring that any disease of the udder certified by a veterinary surgeon to be tuberculous in character shall be deemed to be a "disease" for the purposes of the Dairies and Cowsheds Order. The issue of these several documents is of distinct importance. In the first place, it makes the fact quite clear that the Government have no present intention of resorting to fresh legislation on the subject of tuberculosis, notwithstanding that the recommendations which were made by the second Royal Commission on Tuberculosis and which were held to be essential to the proper control of that disease in so far as its communication to man is concerned were stated to be *dependent on new legislation. From several statements* which have been made it would almost seem that this disinclination to take new statutory powers has some connexion with an alleged uncertainty as to the effect of tuberculin when used for diagnostic purposes in the bovine *animal*, but as the use of this preparation has only a remote concern with any measures necessary for the purposes of human health we must express our great regret that a number of measures which would tend to control tuberculosis in man have been neglected owing to a consideration which is altogether of a secondary character. And even as regards the regulations and the Order issued we could have wished for action which showed greater concern for the protection of public health than we find in these documents, but at the same time we are glad to note that they indicate a distinct step in advance, and we trust that before long the intelligence of the country will demand more advanced measures in the direction of precaution and of the prevention of disease than are possible in the present state of [illegible] unless the vaccination officer

that in the future the objections raised by the anti-vaccinationists' counsel will not be allowed to hoodwink the magistrates. Law is in no sense an accurate science and it is altogether impossible to predict what any given exponent or administrator of it may at any given time elect to interpret into any given section of the Vaccination Acts. Although under existing arrangements evasions of justice should be far less frequent than heretofore, it is very essential that the vaccination officer shall see that each of the steps taken in relation to any given child shall be in exact accord with the Acts and the Vaccination Order. Each vaccination officer throughout the country should take care that he is provided under Article 12 of the Vaccination Order, 1898, with a copy of the resolution appointing him to office. With this in his possession he will be in a position to take such proceedings as he deems desirable. He should, however, be sure of his ground in every case and he should not hesitate to seek legal assistance whenever he considers it wise thus to fortify himself. An average vaccination officer is not quite a match for a clever barrister, unless, that is to say, he has had extensive experience in conducting vaccination prosecutions; and it may be well, in the first few cases at least, for the vaccination officer to avail himself of his powers to procure expert assistance. It is, too, incumbent upon clerks to boards of guardians to make themselves thoroughly familiar with the terms of the new Vaccination Order and to follow all the decisions which may be given with regard to it. And, lastly, the public vaccinator must do his share towards the successful issue of any proceedings by conducting each step of his action with regard to children whose names are forwarded to him by the vaccination officer in exact accordance with the terms of his instructions. Unless he does this and, moreover, keeps an accurate record of his dates, &c., he is not following out the terms of his contract or assisting the cause of vaccination as he should do.

THE INFECTIOUSNESS OF PHTHISIS.

AT the Folkestone County Court on Tuesday last a case of direct interest to the medical profession as well as to hotel-keepers and their patrons the public was heard before Sir William L. Selfe. It was a claim by the Leas Hotel Company against the executors of Mr. Radclyffe Radclyffe-Hall, a gentleman who died in the hotel in October last. It appeared that the deceased went to Folkestone from Cannes and stayed at the Leas Hotel for a few days on his return to this country. He was in very weak health and the late Dr. C. E. Fitz-Gerald saw him on the day before that on which he died and subsequently gave a certificate that death was due to tuberculosis. He informed the manager of the hotel that the disease was infectious, although it was not included in the list of notifiable diseases, and advised that the furniture should be removed, the bedding destroyed, and the room disinfected. The estimated cost of this altogether was £19 13s. 6d. and a claim for this amount was made against the executors who disputed liability. It was stated that the articles of furniture had not been destroyed, the wall-paper had not been removed, and the woodwork had not been repainted. But the room had been disinfected and shut up for a month and afterwards left to air for a fortnight. The plaintiffs therefore amended the claim and asked to be awarded the sum for the rent of the room during the time when it was not occupied. Mr. Yunge-Bateman, the medical officer of health of the borough, gave evidence that tuberculosis was now regarded by the medical profession as infectious and said that they were trying to get it recognised as such. In his opinion all that Dr. Fitz-Gerald had recommended was essential in the interest of the public, as it would be unsafe for any other person to occupy the room until it had been thoroughly purified. A long legal argument ensued as to a customer at an hotel being liable to pay anything under such circumstances, and it was also contended on behalf of the defendants that the cause of death had been wrongly given by Dr. Fitz-Gerald, inasmuch as the deceased had been suffering for years from a bladder complaint and had undergone a serious operation two years ago for that complaint and his illness was simply general debility consequent upon that operation. He had been attended by several eminent physicians and it had never been said that he had chest disease, although one had advised him to be careful of his chest. The solicitor for the plaintiffs and the barrister for the defendants were unable to cite any case as a precedent and His Honour said that the case was quite new in his experience. He held, however, that hotel-keepers were entitled to compensation under such circumstances and that he could not go behind the certificate of the cause of death given by the medical man who attended the deceased in his last illness. It was not shown that the Leas Hotel Company had really lost anything by being unable to let the room as it was closed during the dull season, and it was admitted that there were several other unoccupied rooms in the hotel. The only sum which they were legally entitled to recover, in his judgment, was the 15s. paid for disinfecting the room and he gave judgment for that amount. Counsel for the defendants then asked for leave to appeal, contending that it raised a point of very great importance to hotel patrons, but His Honour declined to grant leave as the amount was so small. If the application was pressed he should give costs against the defendants on the higher scale. The judgment was therefore acquiesced in.

"CRAW-CRAW" AND ITS TREATMENT.

A RECENT number of the *Archives de Médecine Navale* contains a short paper by Dr. J. Emily, a French naval surgeon, on the nature and treatment of a complaint which is known in Eastern Africa as the craw-craw. This account, we are informed in an editorial note, was despatched from Fashoda on Dec. 8th, 1898, by its author who is a member of the Marchand expedition. Craw-craw, says Dr. Emily, is an affection of the skin which is well known to all medical men who have visited the French Congo or the Upper Ubangi district. Its appearance and the highly characteristic course which it pursues constitute it a distinct morbid entity. Commencing as a small reddish-brown macula, situated usually on the lower extremities but also on the dorsal aspect of the hands and elsewhere, the disease from the first is attended by an intolerable itchiness which forces the sufferer to scratch himself violently. A craw-craw ulcer when fully established is encircled by a zone of inflamed skin of the colour of wine lees and may attain to the dimensions of a five-franc piece. It consists in an excavation with nearly perpendicular sides and a granulating bottom whence thickish pus exudes. When exposed to the air this secretion hardens, covering the surface of the sore with a dense impermeable pellicle beneath which the pathogenic agents, whether specific or otherwise, doubtless pullulate freely. Craw-craw has been ascribed to the gonococcus, but Dr. Emily is by no means sure that this view is correct and he hopes on a future occasion to be able to settle with certainty the identity of the microbe. Be this as it may, there can be no doubt regarding the highly contagious character of the affection. In the opinion of several observers mosquitoes and chigoes are to be held responsible for implanting the germs of craw-craw in the human subject, but this view does not commend itself to Dr. Emily. The chigoe abounds on the Gaboon littoral and infests the route between Loango and Brazzaville. The inhabitants, natives as well as Europeans, are infested by mosquitoes, while their feet and sometimes their hands are ruined by the chigoe, but Dr. Emily never met with a case of craw craw among the blacks of the Lower Congo. The wounds made by the insect pests and enlarged by scratching may serve as ports of entry to the specific germs, but apparently the latter do not reside in the irritant liquid which is injected beneath the epidermis. Craw craw ulcers are invariably multiple and may occur all over the body. Dr. Spire of Ubangi has met with them on the penis where they simulated chancres, the resemblance being accentuated by inguinal adenopathy. The treatment of craw-craw has hitherto been most unsatisfactory, apparent cure after lengthened medication being almost always followed by relapse So inveterate, indeed, did Dr. Emily find the complaint that in spite of all his efforts several members of the mission who had acquired craw craw in Western Africa were still suffering therefrom on arrival in the Nile basin. At length it occurred to him to make a trial of boric acid and *as far as* he has gone the results have been well nigh magical But the drug must be given a fair chance of coping with the germs at close *quarters in the following manner.* All hair in the vicinity of the ulcer having been removed the next procedure consists in an energetic washing with soap, brush, and a corrosive sublimate solution This portion of the toilet over, the craw-craw itself is next cleansed by means of a similar solution and tepid boiled water. The base of the ulcer thus exposed will be found to be granular, tortuous, and purulent Dr Emily then proceeds to swab out the cavity with well squeezed plugs of lint, nor is he content until the pus is replaced by sanguineous oozing As may be supposed this stage of the process is a painful one, but it does not last very *long and is absolutely essential* Pure pulverised boric acid applied freely, boricated vaseline, and antiseptic bandaging complete the operation The pain quickly disappears, being followed by a *sensation of* great comfort and when after five or six days the appliances are removed the craw craw will be found to be completely cicatrised Dr. Emily gives the details of four cases which were treated in this way with the utmost success

"CUBITAL ANALGESIA" IN THE INSANE. A VALUABLE DIAGNOSTIC SIGN

FIVE years ago an Italian observer (Biernacki, in *Neurologisches Centralblatt*, 1894) noted that the peculiar painful feeling with tingling felt along the course of the ulnar nerve and the slight muscular contraction in the little finger and hypothenar eminence, following upon pressing and nipping the ulnar nerve trunk at the back of the elbow, were absent in *a considerable number of patients suffering* from locomotor ataxy. In the following year Cramer noted that this "cubital analgesia" was very common among general paralytics in lunatic asylums, reaching as high as 75 *per cent* The attention of alienists being thus directed to the subject, various observations were made on the frequency of this sign in lunatics other than general paralytics to establish its value, if any, in differential diagnosis Mundel stated[1] that from *his observations at the Berlin Polyclinic* on tabes, general paralysis, and other neuroses he considered that this sign was of great importance In the present year Dr P. Keraval,[2] superintendent of the asylum at Armentières in France, has published the results of a systematic examination of 626 asylum patients—viz , 84 general paralytics and 542 other lunatics (melancholiacs, dements, imbeciles and degenerates, idiots, maniacs, alcoholics, &c)—carried out by *himself and his assistant,* Dr. Laurent, with the *following* results —Of 18 general paralytics at an early stage 10 showed "cubital analgesia," two were doubtful, and six were normal, of 30 at a medium stage 12 showed "cubital analgesia," two were doubtful, and 16 were normal; and of 36 at an advanced stage 22 showed "cubital analgesia," four were doubtful, and 10 were normal. Thus of 84 general paralytics at various stages 44 showed "cubital analgesia," eight were doubtful, and 32 were normal Of the other lunatics who exhibited the symptom the ratios were: dements, 87 per cent; idiots, 85 per cent; degenerates, 40 per cent; melancholiacs, 32 per cent; chronic delusional cases, 30 per cent; maniacs, 19 per cent; alcoholics, 10 per cent.; while epileptics showed normal feeling in all the cases—20 in number were examined. It will thus be seen *among lunatics* that excluding the cases of idiots and dements—i e , all cases of profound arrest of growth or degeneration of the brain—the greatest percentage *of patients who exhibit this sign is* composed of general paralytics, of whom 52½ per cent have cubital or ulnar analgesia This symptom must therefore, the writers think, take rank *next only to the already known* physical signs—viz , inequality of the pupils with loss of reaction to light and tremors of the tongue and lips, with indistinctness or hesitancy of articulation — which characterise general paralysis of the insane even in its early stages.

MYELOPATHIC ALBUMOSURIA.

AT the meeting of the Royal Medical and Chirurgical Society on March 14th Dr Bradshaw and Dr Warrington of Liverpool made a most interesting communication on a rare case which clinically was at first characterised by the persistent occurrence of albumose in the urine which was present till death Shortly *before death indications of softening* of the ribs and the sternum appeared and at the necropsy it was found that the softening of bones was due to multiple *myelomata* The association of albumosuria and multiple tumours of bone has been recorded previously, the first case being by the late Dr Bence Jones in 1847, but in all of these the bone lesions were only discovered after death Dr Bradshaw and Dr Warrington's case appears to be the first in which the diagnosis was made during life The name of "myelopathic albumosuria" which they propose to give to the condition is an appropriate and convenient one and will *distinguish it from other forms of albumosuria* which are often associated with granular contracted kidney and with diseases attended by much formation of pus such as empyema

THE CONSERVANCY OF THE RIVER LEE.

THE condition of the River Lee, as our readers are aware, has for a long time past been in a most unsatisfactory state. In the articles which we published on the metropolitan water supply we called attention to the condition of the intercepting drain which belongs to the East London Water*works Company* and was made *for the purpose of lessening* the impurity of the river at the intakes of the company We pointed out that the effluents which passed into the drain from the sewage farms of two of the local authorities were in a disgraceful state The Conservators have certainly not exercised proper vigilance in this matter. The barge owners who use the Lee Navigation have also just cause for complaint as to the condition into which the waterway has been allowed to pass When a *public* body neglects its duties it is sometimes best radically to change its constitution This idea was strongly held by the London County Council who in a Bill which they introduced into Parliament this year proposed to entirely alter the constitu*tion of the present* Lee *Conservancy* Board. The proposition of the London County Council was that the board should consist of 14 members, of whom seven should be appointed by themselves, and that the counties of Bedfordshire, Hertfordshire, and Essex, the corporations of West Ham and of London, the council of the administrative county of Midd water companies should elect one representative each. The proposition that the London County Council should have the appointment of seven members and that the county of Hertfordshire should have only one member seems on the face of it absurd, and possibly the London County Council made this quaint proposition simply with a view of showing that "something should be done." This effect at any rate has been produced. The London County Council Bill came up for second reading in the House of Commons on Thursday, March 9th, when Mr. Cecil, member for the Hertford division of Hertfordshire, announced that the Lee Conservancy Board had passed a resolution to the effect that "if the clauses relating to the Lee Conservancy be withdrawn from the present Bill the Lee Conservancy Board will themselves promote a Bill in the next or following session of Parliament for the reconstitution of the Board in such manner as to make it representative of all the interests of the river Lee." Mr. Cecil announced that the Hertfordshire and Bedfordshire members of Parliament had come to the decision that it would be well for the Lee Conservancy Board to promote a Bill on the lines indicated and that they would be ready to do so if the London County Council dropped that part of their Bill referring to the Conservancy of the Lee. Mr. James Stuart, member for Shoreditch, who was responsible for the Bill, withdrew the clause which had reference to the Lee on the understanding that a Bill will shortly be promoted by the Lee Conservancy Board. The purity of the Lee water and the navigation of the river are of very great importance and we are of opinion that they should be dealt with by the Government. The enormous amount of good which has been effected by the Thames Conservators during the last few years has shown what can be done in the way of river purification. We are of opinion that the best solution for the present difficulties concerning the Lee would be to place it under the care of the existing Thames Conservancy Board. The present Conservators and their officers have now had considerable experience as to the methods by which improvements can be brought about in the Thames and its chief tributaries, and it would be a great advantage that the duty of conserving the Lee should be placed in strong and experienced hands. We do not think that any exception could reasonably be taken to placing the Lee under the Thames Conservators if a small number of members representing the interests of the counties concerned were added to the Thames Conservancy Board. It would be a great mistake to increase the numbers of the Board so as to make it an unwieldy body, but we think that all interests would be properly represented by a very small addition to the existing Board.

ANNIVERSARY DINNER OF THE MEDICAL SOCIETY OF LONDON.

THE 126th anniversary of the founding of the Medical Society of London was celebrated on March 8th by the Fellows and their guests dining at the Hotel Métropole, the President, Mr. Edmund Owen, being in the chair. There was a record attendance, 168 sitting down to dinner, and the well-known hospitality of the society on these occasions had been exercised to an unusual extent. Among the guests were Sir Samuel Wilks, Sir William Mac Cormac, Sir Henry F. Norbury, and the Presidents of practically all the medical societies meeting in London. After the usual loyal toasts had been duly honoured, Mr. Owen proposed the toast of "The Medical Society of London" in an eloquent and humorous speech and in welcoming the guests, informed them that social relaxation in the past had played an important part in the history of the society. He gave a graphic account[1] of a quarrel and schism in the society in 1774, the year after its foundation, which led to the resignation of the President and the secretaries, and of the way in which Lettsom smoothed over the difficulties and led to the return to the society of the revolted members. Lettsom cemented this reunion by regaling the Fellows in 1775 on a turtle which had been presented to him. The ancients believed that the earth rested on the back of a tortoise and Mr. Owen believed that the prosperity of the society was "based on the carapace of that turtle." Following the toast of the evening came the presentation of the Fothergillian Gold Medal to Dr. S. Monckton Copeman for his researches on glycerinated calf lymph which had led to such excellent results. Dr. Copeman was very loudly cheered. Dr. West proposed the toast of the visitors to which Sir Samuel Wilks, Bart., and Sir William Mac Cormac, Bart., K.C.V.O., responded. The health of the President was proposed by Dr. Ord who referred not only to Mr. Owen's fulfilment of his office as President, but to his personal qualities which would have ensured him distinction whatever profession he had adopted. The toast was received with musical honours and Mr. Owen replied. An excellent musical programme was arranged by Dr. Robert Maguire which added greatly to the enjoyment of the evening and included pianoforte solos by Mr. Plimmer, a violoncello solo by Mr. Ronald Carter, and two songs by Mr. Foster Ferguson which were loudly encored.

SUGAR "AS A MILITARY ALIMENT."

DR. JOSEPH DE PIETRA SANTA has recently published an interesting paper in the *Journal d'Hygiène*,[1] of which he is editor, on the merits of sugar "as a military aliment." It was long believed, he says, that sugar caused constipation and was moreover "*heating*," an ill-defined term greatly in vogue a generation or two since. In the opinion of many distinguished members of the medical profession sugar became unwholesome when it was consumed in anything but small quantities, causing ulcers in the mouth with softening of the gums and also predisposing to scurvy. Requiring a large amount of gastric juice for its proper solution it consequently soon fatigued the stomach, while at the same time it favoured worms and weakened the chest. By degrees, however, more enlightened views began to prevail. Physicians in various countries became converted and in France the celebrated hygienist, Michel Lévy, constituted himself the champion of the maligned product, preaching the doctrine that Nature herself taught us to make use of sugar inasmuch as she combined with it many tasteless or acid substances which otherwise would remain unpalatable. Cruveilhier likewise supported sugar from the coign of vantage of his professorial chair, declaring that its evil reputation was a libel, while Proudhon was responsible for the aphorism that "sugar constitutes the poor man's pharmacy, being injurious solely to the pocket." By this time the alimentary status of sugar is no longer doubtful. The pariah of yesterday has grown into the spoilt darling of the dietitians of to-day, the change being in a great measure due to the ever-increasing army of cyclists whose sagacity was not long at fault in recognising the value of sugar not merely as a trustworthy respiratory food but also as a potent and speedy recuperator in muscular weariness. In December, 1897, the question of the usefulness of sugar as a food for soldiers was raised in the German Parliament by Dr. Paasche who based his argument on some experiments which had been undertaken by Staff Surgeon-Major Schumburg and in consequence of the discussion that ensued a further investigation under Dr. Leitenstorfer took place at Metz during the annual manœuvres. 20 men having been selected from each company of a regiment, all of them resembling each other as much as possible in physique, general health, &c., an extra ration of 100 grammes of sugar was issued to half of the whole number. The results are said to have been conclusively in favour of the sugar eaters. They increased in weight while their comrades did not, they enjoyed much better health, and they were also able to support the hard work with much less distress. The use of a lump or two of sugar is described as acting like a charm not only against fatigue but also in quenching thirst; and none of the men who consumed the extra ration felt in the least surfeited by it. The French soldier, it seems, only gets two and a half grammes of sugar daily, whereas his English congener's allowance is 37 grammes. "How far we are behind this practical people!" exclaims Dr. de Pietra Santa.

THE CHAIR OF PHYSIOLOGY IN EDINBURGH UNIVERSITY.

As announced in our advertising columns last week, the preliminary steps are being taken with a view to filling the chair of physiology left vacant by the lamented death of Professor Rutherford. On account of the important interests involved it is essential that both the patrons who decide the appointment and also the intending candidates should have ample time in which to complete their arrangements. Applications are now invited and are to be sent not later than Saturday, May 20th next, to the secretary to the curators of patronage, Mr. R. Herbert Johnston, W.S., 66, Frederick-street, Edinburgh. Each candidate must send eight copies of his application, one of which should be signed, and must also send eight copies of any testimonials which he may desire to submit.

GENERAL PARALYSIS OF THE INSANE IN MOTHER AND CHILD.

THIS rare condition has been very rarely recorded, and a recent interesting case (with results of the post-mortem examination) published by Dr. Oscar Müller in the *Allgemeine Zeitschrift für Psychiatrie*, June, 1898) calls for special notice. The mother, a woman aged 45 years, had had syphilis and had given birth to two children, one of whom died from infantile convulsions. This child showed evidences of congenital infantile syphilis. The other child grew up apparently in good bodily health and as regards her mind she was an average and even promising child. At the age of 10 years, however, she began to exhibit loss of intelligence, could not keep pace with her schoolmates, and soon became quite dull and stupid. From being a clever skater she soon became an incapable one, while her handwriting also rapidly failed and grew confused and illegible. Her increasing mental dulness passed into a profound apathetic dementia; she was reduced to an idiotic and helpless condition, in which state she died. The mother shortly before this began to show signs of mental and moral deterioration and probably the onset of the climacteric period tended to hasten the *dénouement*. She developed extreme conjugal jealousy and then she became careless and neglectful of her own appearance and took to drink. At this time a slight defect of articulation developed; this became marked and finally there was actual paresis of the muscles of articulation, with tremors of the tongue and lips. Her mind now rapidly and steadily lapsed into dementia and she died shortly afterwards. A necropsy showed her brain to be affected with the typical vascular and meningeal lesions of general paralysis. The child was also examined post mortem and the brain lesions were found to conform to those of the mother. The interest of the case lies not only in its rarity, but also in the fact that the necropsies disclosed the lesion which was diagnosed during life. Further interest attaches to the fact that the case of the daughter was one of that rare type of disease known as "juvenile general paralysis." It may be mentioned that cases of such similar heredity are quite rare, and when they do occur there has generally been associated with them a history either of personal or congenital syphilis. The latter is a factor of such predominating frequency that it leaves no doubt as to the fact that the chief cause of juvenile general paralysis is congenital syphilis. The larger question, however, as regards the agency of acquired syphilis in determining the appearance of general paralysis in adults is unfortunately not settled by the evidence of cases such as the above, though the weight of evidence inclines to view syphilis as an accessory and contributory factor with others, such as general excess and intemperance.

BLACKWATER FEVER.

THE paper which is to be read before the Epidemiological Society of London to-night (Friday) on this interesting but imperfectly understood condition is probably looked forward to with much interest by epidemiologists. Mr. W. H. Crosse, the reader of the paper, was for some years Principal Medical Officer to the Royal Niger Company and in this capacity he had unusual opportunities for studying the manifestations of this condition and its relations to malarial fever, to paroxysmal hæmoglobinuria, and to quinine poisoning. As to the distribution of this abnormal state we have yet much to learn, and it must be said that having regard to the large number of our countrymen who spend most of their existence in those of our colonies where malaria obtains it is of great importance that our knowledge on the subject should be extended.

THE MEDICAL FACTOR IN IMPERIAL EXPANSION.

THE "white man's burden" is a complex as well as a weighty one and its medical constituent is as important as any. This was admirably put by Professor McKendrick at the mass meeting held last week in Glasgow on the subject of medical missions. No other nationality has combined, as has the British, colonial development with civilisation—civilisation of which the inferior races sooner or later feel the benefit and from which they take "a new departure" in their evolution. True, in the sixteenth and seventeenth centuries Francis Xavier and his followers, mainly belonging to the Society of Jesus, did splendid work in East Africa and in South America, but that work was too closely identified with religious proselytism to be thoroughly healthy or lasting. Their successors in practice have admitted as much. The Capuchin monk Massaia (afterwards promoted to be cardinal) took a leaf out of English-speaking missionary effort when he made Bible instruction to come after, not precede, physical and moral rehabilitation. In the Galla country 50 years ago he taught the savage population the arts of peace (mainly agricultural industry) before translating for them and interpreting the Sermon on the Mount. But his most effective resource was of a medical nature and he owed his wonderful command of native sympathy and allegiance more to his having stamped out small-pox by vaccination than to any other of his benefactions. Among all the incidents brought to light by the Fashoda difficulty, none was more significant than the friendly reception accorded to Major Marchand by the natives from the mistaken notion that he was English, so universal is the native impression that of all the "white men" who invade Equatorial Africa, those of British
nationality
the most to
able

English-speaking expansion over that of its other European competitors in the strongest light—a superiority due to the civilising energies and aptitudes of the race, using as a main instrument the medical missionary. Scotland has an honourable record in this field of enterprise, from Mungo Park to David Livingstone and the noble band of volunteers to whom the regions round the Equatorial lakes are already so deeply indebted. The faculty which he represented in Glasgow University took, said Professor McKendrick, "the deepest interest in medical missionary work." Long may it continue to do so, thus making medicine the handmaid of physical and moral evolution and promoting spiritual reclamation with a success which religion, single-handed, has never known.

"ANTI-VIVISECTION."

AN institution that desires to be known as the National Anti-Vivisection Hospital is advertising for funds. A noble lord and a lady whose name is not given have promised sums of £50 and £10 respectively if a given number of persons will also oblige with donations of equal value. The programme which the promoters of this foundation lay down for it is brief and is as follows: "No vivisectors on its staff; no vivisection in its schools; no experiments on patients." There is here an obvious omission and one which no doubt the intending donors of £50 and £10 will desire to see supplied before drawing their cheques. A fourth rule should run to this effect: "No operation will be performed and no drug will be administered in this hospital the effect of which has been discovered or verified in any degree by means or with the aid of experiments on living animals," all such experiments being presumably included in the word "Vivisection" as used in the advertisement. The precise meaning of the expression "experiments on patients" needs further definition. Either the surgeons in this institution are to profit by operations successfully performed for the first time elsewhere by other surgeons, but are not to be trusted to take steps without precedents to follow, or a wider principle is suggested for universal guidance similar to that enjoined by the fond but Hibernian parent who forbids a child to enter the water until he has learnt to swim. In whatever way it may be regarded every deviation, however slight, from established practice is necessarily an experiment the first time it is made, aye and until the deviation has itself become recognised as necessary when occasion demands. But now we are beginning to pay the faddist the useless compliment of reasoning with him, whereas he will not even gracefully reply by submitting to us a schedule of the operations and drugs that he would permit under the limitations which we have suggested and which are the logical complement to those already propounded.

RIVER POLLUTION: THE MERSEY AND IRWELL DISTRICT.

AT a meeting of the Mersey and Irwell Joint Committee held on March 6th Sir Henry Roscoe presented a return of a series of analyses of sewage effluents and of the waters of the Ship Canal and of the rivers in the district. Of 36 samples of effluent taken 26 were either good or fair, the unsatisfactory effluents mainly coming from tanks. The tables concerning the effluents showed that the difficulty of dealing with the sewage was mostly felt in the large towns. Since the committee began its work, however, their knowledge had been much extended and he felt that even in large towns the difficulties which presented themselves could be overcome. There was no doubt of considerable progress having been made and this progress was especially noticeable in the condition of the rivers themselves. Many cases had come before them in which water could be used for manufacturing purposes which could not be so used before the committee began its work. It was satisfactory to know, too, that the committee had not interfered with trade. No single instance had occurred in which a manufacturer had to leave the district by reason of the action of the committee. The returns were of considerable interest. They had hitherto not been able to state definitely what the condition of the rivers was. He had the results of a very complete system of analyses of the waters of the ship canal and of the rivers in the watershed. 63 samples had been taken from the Ship Canal and analysed and they had obtained a fair idea of the condition of the water generally. It had been said that the composition of the water in the canal was worse than the effluent from the local authorities. This was proved by analyses not to be the case. 69 samples had been taken from the streams. It was found in all cases that the condition of the water deteriorated the further they went from the source. Although they could not tell exactly the improvement which had taken place in the condition of the streams during the last few years there was no doubt that some improvement had taken place. The samples related to the Irk, the Medlock, the Mersey, the Irwell, the Roach, and the Beal. The Irk was by far the worst of the streams; the Mersey and Irwell were not nearly so bad. The reason for this will no doubt be the subject of investigation.

CONVERSAZIONE AT THE MIDDLESEX HOSPITAL MEDICAL SCHOOL.

A CONVERSAZIONE was held on Wednesday, March 15th, on the occasion of the inauguration of the new school buildings. Guests were received in the board-room by the chairman of the council, the senior physician, the senior surgeon, and the dean. The new school buildings consist of two blocks—the Garden block and the Union-street block. The Garden block contains the large lecture theatre, the bacteriological research laboratory, the museum, the chemical department (with laboratory, lecture theatre, and lecturer's private laboratory) the pathological and bacteriological laboratories, the room for operative surgery, and the dissecting-room. In the Union-street block are two physiological laboratories and some class-rooms. All the laboratories have evidently been fitted up with very great care and are admirably adapted for the purposes for which they have been designed. They are well-equipped with all needful apparatus. Many objects of interest were on view in the various rooms, and among them may be mentioned the following. In the large lecture theatre Messrs. Muirhead and Co. exhibited Mr. Mackenzie Davidson's apparatus for localisation in skiagraphy, and especially neat was a portable form of the apparatus intended for use by army surgeons in the field. Mr. Mackenzie Davidson also showed stereoscopic skiagrams by means of Wheatstone's stereoscope. In the bacteriological research laboratory was an interesting series of specimens prepared by Mr. A. G. R. Foulerton illustrating the successive steps in the complete bacteriological diagnosis of pulmonary tuberculosis. In the museum Dr. Voelcker and Dr. Campbell Thomson showed many recent additions to the museum prepared by the Kaiserling method which so successfully retains the normal appearance of the tissues. Dr. Voelcker also kindly lent for exhibition a fine and valuable collection of archaic medical works. In the chemical theatre were to be seen the spectra of the latest additions to the list of elements—namely, neon, krypton, and xenon; these were exhibited by Professor W. Ramsay and Dr. Travers. In the anatomy lecturer's room was an exhibition by Messrs. Schall of electrical apparatus adapted to medical purposes. In the pathological and bacteriological laboratories were many microscopical preparations of morbid histology and some original paintings and drawings by Sir Charles Bell; there were some very interesting microscopic sections of yeast tumours and some showing mycosis of the lung. Two species of filaria—namely, perstans and nocturna—were also shown. Messrs. Swift and Son showed many microscopes and microscopic preparations, and surgical and scientific instruments were exhibited in the dissecting-room by Messrs. Allen and Hanbury, Mr. C. Baker, Messrs. Curry and Paxton, Messrs. Krohne and Sesemann, and Messrs. Maw, Son, and Thompson. In the physiological laboratory Mr. Somerville Hastings gave a demonstration of the action of the auriculo ventricular valves in the heart of the ox, and Dr. J. J. Pringle exhibited many striking water-colour drawings of rare skin diseases. In the entrance hall were to be seen the skeletons of the originals of Landseer's "Dignity and Impudence." The band of the Royal Artillery performed a charming selection of music in the museum during the evening.

THE PETROLEUM BILL.

THIS Bill, in which Mr. Harold J. Reckitt sought to raise the flash-point of oil for lighting purposes from 73° to 100° F, was rejected on a division on the second reading in the House of Commons last Wednesday by a majority of 85, the figures being 159 for and 244 against. We have throughout entertained doubt whether the Government would be led, in view of the recommendation in favour of raising the flash-point being sustained by so narrow a majority of the Petroleum Committee, to legislate in this direction Interest will now turn on the proposals which the Government will make in their Bill which Mr Jesse Collings has promised to introduce shortly. We are entirely with those who are studying the question solely from the point of view of public protection, and trust that whatever measure may be proposed it will be one calculated to protect life and limb.

WE are informed that Dr. Curnow, Dr. John Anderson, C.I.E, and Mr. G. R Turner, have signed a joint letter resigning their posts as physicians and surgeon, respectively, to the Seamen's Hospital Society, but offering to continue the performance of their duties until their successors are appointed. Mr. Donald Gunn, the ophthalmic surgeon, has also resigned his post We shall refer next week to the circumstances which have thus left the *Dreadnought* Seamen's Hospital, Greenwich, without any honorary medical staff.

A COURSE of lectures on Diseases of Tropical Climates will be delivered by Dr Patrick Manson in the Medical School of St. George's Hospital on Tuesday, May 16th, and every succeeding Friday and Tuesday till July 18th, at 5 P M each day. For information with regard to the course application should be made to the Dean of Medical School.

SIR T. NAGHTEN FITZGERALD, F R C S Irel., who has been elected president of the Medical Society of Victoria for the ensuing year, is an Irishman who was born in Dublin 64 years ago. He is the senior surgeon to the Melbourne Hospital in Victoria and was knighted in 1897.

WE understand that the Society of Apothecaries of London intend to have the question, temporarily decided by the case of "Hunter *v.* Clare," as to the right of a Licentiate of the Society to style himself "physician," reopened at an early date.

THE annual meeting of the Asylum Workers' Association will take place on Monday, March 27th, at 3 30 P M, under the presidency of Sir J. Crichton Browne, M.D. Edin, F.R S., at 11, Chandos street, W.

DR. THOMAS BARLOW has been appointed to fill the vacancy in the body of the University of London Commissioners caused by the resignation of Sir William Roberts, M.D. Lond.

WE regret sincerely to learn of the death of Major James W. Evans, I.M S, Professor of Pathology in Calcutta Medical College, from plague.

THE LAW IN REGARD TO THE PROFESSIONAL SECRECY OF MEDICAL PRACTITIONERS.

THE following is the memorandum on this subject prepared by Mr. Muir Mackenzie at the request of the President of the General Medical Council with the concurrence of the Executive Committee for transmission through the Home Secretary to the Russian Ambassador who had asked for information for the use of his Government

Memorandum on the Law of the Obligation of Medical Practitioners with regard to Professional Secrecy

There are two aspects of the question of professional secrecy of medical practitioners—namely, first whether a medical man can be made to divulge professional confidences in a court of law and, secondly, whether he may under any circumstances be permitted to divulge professional confidences in the intercourse of daily life

(1) As regards the first question it is settled law that a medical man cannot claim the privilege to which lawyers have been held to be entitled, of refusing to disclose matters communicated to them professionally "A surgeon has no privilege where it is a material question in a civil or criminal cause to know whether parties were married or whether a child was born to say that his introduction to the parties was in the course of his profession and in that way he came to the knowledge of it If a surgeon was voluntarily to reveal these secrets to be sure he would be guilty of a breach of honour and of great indiscretion, but to give that information in a court of justice, which by the law of the land he is bound to do, will never be imputed to him as any indiscretion whatever"—per Lord Mansfield in the Duchess of Kingston's case, 20 S T p 573 The same position is recognised by Buller, J, in Wilson v. Rastall, 4 T R p. 760, where he says, "There are cases to which it is much to be lamented that the law of privilege is not extended; those in which medical persons are obliged to disclose the information which they acquire by attending in their professional characters", and similarly in a later case Lord Chancellor Brougham, after referring to a lawyer's right of privilege, continues as follows: "The foundation of this rule is not difficult to discover, it is not (as has sometimes been said) on account of any particular importance which the law attributes to the business of legal professors or any particular disposition to afford them protection, though certainly it may not be very easy to discover why a like privilege has been refused to others, especially to medical advisers"—Greenhough v. Gaskell, 1 M & K., p 103.

In Rex. v. Gibbons, 1 C P. 97, where the prisoner was indicted for the murder of her child and a surgeon was called to prove confessions made to him Park, J, overruled the objection that the witness was at the time attending the prisoner in his capacity of surgeon, adding: "That is no sufficient reason to prevent a disclosure for the purpose of justice", and the same rule, "that there is no privilege of this description in the case of a medical man," was repeated by Best, C J, in Broad v. Pitt 3 C P 518

From these cases it is clear that a medical man not only may, but must, if necessary, violate professional confidences when answering questions material to an issue in a court of law.

2. Upon the second question there have been, not unnaturally, very few expressions of judicial opinion It is admitted as a general principle that a medical man should not disclose communications made to him in his professional capacity, and in the Scotch Court of Session it has been judicially decided that "secrecy is an essential condition of the contract between a medical man and his employers, and breach of secrecy affords a relevant ground for an action of damages." A.B. v. C D, 14 Dunlop, second series, 177 But upon this rule of the general inviolability of professional confidences (outside a court of law) the custom of the medical profession has engrafted two exceptions, (1) in cases of criminal communications, (2) where violation of secrecy is considered necessary for the protection of wife or children (to which may be added a third exception, suggested by the court in A.B. v. C D, cited above—viz., instances conducive to the ends of science though concealment of individuals should in such cases be secured) These two exceptions were the subject of testimony given by eminent medical witnesses in the case of Kitson v. Playfair in 1896 as being generally recognised among medical men, but they are not judicially recognised as invariable exceptions as is shown by the summing up of Sir H. Hawkins in that case. The defendant pleaded privilege on the ground of the second of the above exceptions, and though the point was not decided owing to the jury finding that the defendant had been influenced by an indirect motive the following passages are relevant to the matter of the obligation of secrecy among medical men On medical evidence as to professional privilege being given Sir H Hawkins said "The question of privilege is for me to decide, and, so far as it concerns that question I shall not be influenced by this evidence."—*Times*, March 26th, 1896

The following passage occurs in the report of the judge's summing up "The medical profession might, no doubt, discuss among themselves rules for their own guidance, but they had not power to impose the rules they made upon the public. The medical men called said there were two exceptions to the rule imposing on them secrecy as to confidences gained during professional attendance.

"The first was as to giving evidence in a court of law. His lordship did not altogether agree with what they said as to that. It all depended on the judge. The judge might in some cases refuse to commit a medical man for contempt in refusing to reveal confidences. Each case would be governed by particular circumstances, and the ruling of the judge would be the test.

"Secondly, that if there were circumstances from which they supposed a crime was intended to be committed they would have to inform the public prosecutor. If the doctor were called in merely to attend a woman needing physical aid, his lordship doubted very much whether he would be justified in going to the police and saying, 'I have been attending a woman who has been trying to procure an abortion.' That would be a monstrous cruelty. Therefore to say there was a general rule was going too far. There was a third exception—namely, a communication between the doctor and his wife or children. That required a great deal of limitation. For instance, there were cases in which the wife did not require protection, and where it would be a wanton act to communicate a secret to her. That was a delicate question, but did not arise in the present case. The law as to words spoken on a privileged occasion was pretty well known."—*Times*, March 28th, 1896.

From this it seems clear that on the question of violation of professional secrecy a medical man is in no more favoured position than anyone else, and further, that circumstances which according to the custom of the medical profession might be deemed to exonerate him from the imputation of improper violation of secrecy might nevertheless in a court of law be deemed an insufficient justification.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

We continue our report of the fifty-seventh sitting of the Royal Commissioners.

In answer to the Chairman Sir Frederick Dixon-Hartland said that the Conservators objected to any power being given to the Local Government Board to "relax" (increase) the limits of the water companies' intake from the Thames. They felt very strongly on this point because Parliament had settled the amount which the companies were to be allowed to draw after a most careful investigation both in the House and before committees. If a Minister had a right at a moment's notice to overthrow everything that Parliament had decided with regard to the amount of water which might be taken the Conservators would not know where they were. They strongly objected to such a change. They had a duty to fulfil with regard to the navigation and it was not right that the Acts passed to enable them to carry out these duties should be set aside for the sake of the water companies.

The Chairman asked whether the Conservators would be satisfied if the discretionary power of allowing more water to be taken should be vested in the Conservancy. The witness replied that if that were done he would state with perfect candour what line the Conservators would take. They would allow the water companies to take any amount of water in time of drought so long as it did not interfere with navigation.

The Chairman said that it had been suggested that instead of an enormous storage which in average years would be useless it might be well in a year of emergency to vest in some body the discretion of saying: "Very well, take more water from the Thames; let the barges go aground for three months if you please." The witness pointed out that it was not only the upper river navigation which the Conservators had to think about: it was the interference with the navigation of the lower part of the river which was the most serious thing.

The Chairman pointed out that the suggestion which he had just made was the way in which the matter had been put to the Commissioners by the metropolitan water companies—namely, that it would be better in an exceptional period that a little inconvenience should be suffered below the last weir than it would be to spend millions of money in making reservoirs which would perhaps be only required once in half a century. The witness pointed out that the Conservators had at the present time, as a matter of fact, discretionary power to allow the water companies to draw more than their statutory limits. They were not compelled to ask for an injunction against the companies if they drew more than they ought, and they had not done so as a matter of fact. To take an instance, they had not exercised their powers against the Southwark and Vauxhall Company for many years, although they were taking more than they were allowed by Parliament. They exercised their powers when the Southwark and Vauxhall Company declined to make provision for any storage at all.

Major-General Scott suggested that the demands of navigation would have to give way if there was an absolute scarcity of water in London. The witness said that the companies were bound to go somewhere else into their own districts as, for instance, the New River Company had been. It was not for the Thames Conservators to save them from the expense of making storage reservoirs; it was the duty of the water companies to supply their customers and to make the necessary arrangements for doing so.

The Chairman suggested that the power of exemption with regard to the statutory limits of the intake of a company would only be extended in an extraordinary emergency like that of last year. The witness replied that as far as the Conservators were concerned they would not interfere with an over-draught from the Thames if the navigation was not thereby interfered with. At the present time barges had some difficulty in getting under Kew Bridge. It was necessary that a certain amount of water should pass down from the upper river to clear away the mud. This accumulation was due to the fact that a sufficient amount of water had not recently passed down. At least 200,000,000 gallons should be allowed to pass daily over Teddington Weir.

In answer to Mr. de Bock Porter, the witness said that the companies ought not to be allowed to take more than 130,000,000 gallons from the Thames on any one day. If the metropolitan water companies were ordered to give storage for 90 days there was plenty of water in the Thames to supply London for a hundred years to come. There was no difficulty in having a sufficiency of water if sufficient storage were provided. The Conservators simply wished that the water companies should be made to provide for a dry season and there would then be no difficulty in the matter.

In answer to Sir John Dorington the witness said that they did not protest against 130,000,000 gallons being taken daily because the matter had been settled by Parliament and they could not help themselves. At the present time, however, the position of the Conservators was this: the metropolitan water companies had been permitted by Acts of Parliament to take this amount and they did not wish to interfere with that arrangement because they would not like to interfere with "vested rights."

In answer to Mr. de Bock Porter the witness said that the Conservators had not a sufficient amount of money at their disposal to carry on all the work of dredging which ought to be done. If the upper channels were deepened more water would come down the river and there would be less difficulty in times of flood, and if more money could be allowed for dredging it would be of the greatest advantage to the river.

In answer to the Chairman the witness said that they had not lately met with much opposition from local authorities with regard to their insistence on the prevention of pollution. Lord Valentia lately brought a deputation to meet them and the amusing part of it was that Lord Valentia himself represented Oxford and that a representative of a neighbouring authority complained chiefly that Oxford polluted the river and that his clients were not allowed to do the same.[1]

The Chairman asked when were we to have salmon in the Thames. The witness did not name a time, but he stated that smelts now come up as far as Blackwall and that salmon trout are to be put into the river at Sunbury this year.

Sir Edward Frankland in answer to the Chairman said that he obtained the water for his examinations from the filter wells of the Chelsea, West Middlesex, Grand Junction, Southwark and Vauxhall, and Lambeth Companies. The witness handed in a diagram and in answer to the Chairman he said that there was a rise in the number of microbes in filtered water corresponding with the rise in the number of microbes in the "raw" water, but that this increase was by no means uniform or equal—for instance, in January, 1894, there was a great rise in the number of microbes in the "raw" water and only a slight rise in the number of those in the filtered water, whereas in February, 1895, there was a smaller rise in the number of microbes in "raw" water but a larger rise in the number of microbes in the filtered water. The witness said that these anomalies were capable of a pretty feasible explanation. Different companies have different amounts of storage capacity. The samples of river water and of filtered water were taken on the same day but possibly the storage reservoirs of some of these companies might have been taken from the river a day or two or three days before the flood came and they would then have been using for filtration water containing a lower number of microbes.

---

[1] A report of this meeting appeared in The Lancet of Feb. 18th, p. 459.

In answer to the CHAIRMAN, who said that he always understood language but confessed that he was puzzled by diagrams, the witness said that the microbes increased with the flood.

The CHAIRMAN remarked that they had heard the contrary from high scientific authorities. The witness replied that the opinion he had expressed had been tested by him for several years.

The CHAIRMAN asked if filtration was properly done whether it mattered how many microbes there were in the raw water, whether the water would come out equally good The witness replied that that was Mr. Dewar's opinion, but that it did not agree with his experience and that was why he had made out this diagram as a test of his experiences.

In answer to Major-General SCOTT the witness said that their information about the action of sand filters in removing the microbes was still in a very rudimentary state. He had no doubt from observations which he had been making now for some years that every day the water was stored in a reservoir it improved greatly in its microbial quality Lake waters contained few bacteria, and although the streams which supplied them may contain a great many they disappeared when they got into the lake. For example the sewage of Buffalo goes into the St Lawrence above the falls, the microbes survive that fall and the mouth of the river where it enters Lake Ontario is charged with an enormous number of microbes, but within a mile or two of the entrance of the river the water of the lake is nearly free from microbes. The witness gave it as his opinion that the safest treatment for flood water, and, indeed, for any water, is to put it into a subsiding reservoir.

With regard to the question of filtration the CHAIRMAN asked whether anything had been done to carry out the recommendations of Lord Balfour's Commission The witness said that improvements had been made Lord Balfour's Commission had abstained from laying down any regulations for filtration but had suggested that regulations should be made after inquiry, but the witness did not think that engineers knew enough about the matter to lay down any definite regulations.

The CHAIRMAN asked whether the witness could suggest any system by which the inquiry could be continued and the storage of Thames water could be safely carried on The witness replied that he thought it was possible after efficient filtration to keep the number of microbes below 100 per cubic centimetre and that this was best effected by the use of fine sand on the surface of the filter, for a thin stratum of fine sand was better than a thick stratum of coarse sand The West Middlesex Company uses very fine sand and their filtration is as a rule more perfect than that of any of the other Thames companies which use coarser sand.

Major-General SCOTT asked whether as a matter of fact analysis did not show that the number of 100 microbes per cubic centimetre was frequently exceeded in filtered water supplied by the companies. The witness replied that this was so. There were, however, some points which required further investigation. For his own part the witness did not think that the freezing of the sand in winter caused an increase in the number of microbes. It was difficult to account for the increase—in the middle of summer all the filters of the companies went wrong at the same time The witness did not think it would be right at the present time to impose a statutory obligation with regard to the number of microbes present in the water supplied by a company.

Mr. CRIPPS asked whether those microbes which multiplied so quickly were mischievous at all. The witness said that in the seven years during which he had been making observations he had not been able to catch a mischievous microbe; they might, as far as he knew, be nutritious.

In answer to Sir JOHN DORINGTON the witness said that he examined specimens of water at Reigate and Mr Dewar examined them at Kensington. Water ought really to be examined on the premises of the companies. His laboratory was too far off. It would be best for bacteriologists to take samples and cultivate them on the spot because cultivation should be carried out without delay.

In answer to the CHAIRMAN the witness said that in his opinion the lakes in the north of England contained better water than the Welsh lakes. It was not necessary to go to Wales for an additional supply of water for London; there were other places, notably the lakes of Cumberland and Westmorland. The Lakes District water had been clearly proved by the Duke of Richmond's Commission to be as good as the best Welsh water, and the best Welsh water had been already appropriated by Birmingham and Liverpool. The lakes of Cumberland and of Westmorland had been very little appropriated up to the present time. Thirlmere had been taken by Manchester but Ullswater and Hawes Water were still to be had. The witness said that when he examined Ullswater it was of such excellent quality that it was nearly equal to spring water, and better than that of Thirlmere, which has been appropriated by Manchester.

METROPOLITAN SCHOOLS OF MEDICINE AND THE UNIVERSITY OF LONDON.

THE following memorandum has been signed by the representatives of all the Metropolitan Schools of Medicine and forwarded to the University of London Commissioners.—

1 The schools which are parties to the subjoined memorandum are the Faculties of Medicine in University and King's Colleges and the 10 other Schools of Medicine named by the Gresham University Commissioners for immediate admission as schools of the University of London (Report, p. xxii), viz., the Medical Schools of the Charing Cross Hospital of Guy's Hospital, of the London Hospital, of the Middlesex Hospital of St Bartholomew's Hospital, of St. George's Hospital, of St. Mary's Hospital, of St. Thomas's Hospital, of the Westminster Hospital, and the London School of Medicine for Women. They are educating between them about 3000 students and employ about 400 teachers of various grades.

The organisation of medical education in London on university lines is of long standing, though until now it has lacked direct connexion with, and influence in, a university. The schools submit that no faculty will bring such immediate strength to the remodelled University of London as the Faculty of Medicine.

2. The schools would urge upon the Commissioners that, in the first instance, all the principal teachers of the schools, including the clinical teachers—that is, all those who are not under the control of other individual teachers, but only of the general authority of their school—should be recognised as teachers of the University[1]; and that they, together with the teachers, if any, appointed by the University itself, should be constituted the Faculty of Medicine, with such rights of addressing the University authorities and such representation on the Board or Boards of Studies of the Faculty as the Commissioners may determine

3 In view of the number of teachers and students who will from the outset be concerned in the faculty of medicine in view of the large public interests involved in their work and of the peculiar position of degrees in medicine as being also certificates of competence recognised by the State, the schools submit that the representation on the Senate assigned by the Commissioners to so important a division of the University should not be less than that assigned to any other single faculty.

4 In view of the serious waste of labour at present occasioned in the London schools by the variety of curricula and sets of examinations for which students have to be prepared, and the different times of the year at which the examinations of the several examining bodies are held, the schools trust that the University will endeavour to carry out an important recommendation of the Gresham University Commission (Report, p. xliii) by entering into relations with the Royal Colleges of Physicians and Surgeons for the purpose of holding joint examinations in some parts of the medical curriculum.[2]

[1] The Faculty of Medicine of University College is of opinion that this should apply only *to teachers of purely medical subjects*

[2] The Faculty of Medicine of University College is of opinion that the University should retain the management of its examinations in its own hands.

THE PREVENTION OF TUBERCULOSIS.

IT has become universally recognised that tuberculosis is a preventable disease, that the disease itself is not hereditary but only the predisposition to it, and, lastly, that it is a communicable disease from the sick to the sound—i.e., that the tuberculous animal whether human or not is a source of danger to other animals. These ideas have permeated the country and it is allowed that something should be done towards the consummation of the desired tactics for lessening and in time, perhaps, getting rid of the tuberculous scourge. A National Association for the Prevention of Consumption and Other Forms of Tuberculosis has been formed primarily in London but branches have also been started all over the kingdom. We therefore intend to give in this column an epitome of such proceedings as may be taken by the various authorities, municipal and other, with regard to educating and organising the people in the matter of this important question. Concerning the work of this association we have kept our readers well informed from time to time and we have no doubt that the fact of H.R.H. the Prince of Wales being its President will do more to convince the man in the street of the excellence of its intentions than even the soundness of the pathological doctrines upon which its work is founded.

Cumberland.

A public meeting of the Cumberland Branch of the National Association for Prevention of Consumption and other forms of Tuberculosis was held in the Town Hall, Carlisle, on March 2nd. The meeting had been convened by the Lord-Lieutenant (Lord Muncaster), the High Sheriff (Mr. G. G. Kirklinton), the Mayors of Carlisle, Workington, and Whitehaven, and the Chairman of the County Council. There was a large attendance of medical men and county councillors.

Dr. R. W. PHILIP of Edinburgh, who had been specially invited, spoke of the importance of the open-air treatment and referred to the Edinburgh sanatorium.

The Bishop of CARLISLE, in moving the first resolution—i.e., that constituting the meeting a branch of the National Association—made an admirable speech in which he mentioned the great influence that the clergy should have for good in spreading information as to ways and means of prevention.

Other resolutions dealing with the organisation of the branch were put and passed. With a view to the future erection of a sanatorium for the county a number of subscriptions have already been promised, including an anonymous one of £400.

York.

The Sanitary Committee of the York City Council have issued a pamphlet signed by Dr. E. M. Smith and written in very plain, simple language which they commend to the notice of all citizens. It emphasises the necessity and the possibility of prevention if only some simple rules are adhered to. Directions are given as to disinfection and the paramount importance of fresh air and sunlight. Further stress is laid upon infection of milk and the danger of phthisical persons attending upon cattle.

Worcester.

The medical officer of health of the city of Worcester has prepared a report upon tuberculosis which has been issued separately. It deals with the matter under the following heads:—

1. To what extent tuberculosis exists at the present time in man and in cattle.
2. The means by which the disease is conveyed to the healthy from those already infected.
3. The conditions favourable and inimical to the growth and spread of the disease.
4. The administrative procedures that can be taken by sanitary authorities to stamp out the disease and the recommendations of the Royal Commission.

Crewe.

On Feb. 28th a special meeting of the Health Committee of the Crewe Town Council was held to consider the question of the prevention of tuberculosis. Dr. Meredith Young laid before the committee a report on the death-rate from tuberculosis and also a programme of suggested preventive measures. The following were finally agreed to:—

1. That the medical officer of health be empowered to offer facilities for the bacteriological examination of material from suspected cases of phthisis and other forms of tuberculosis, the result of such examination, if positive, to be considered a notification of the disease, but that no action whatever be taken on the receipt of this information except at the request of the medical attendant, the patient, or his relatives.
2. That the medical officer of health be empowered to have the milk-supply to the Isolation Hospital bacteriologically examined from time to time as often as he may deem necessary.
3. That disinfection of houses, bedding, clothing, &c., be done by the Corporation staff free of charge in all cases of tuberculosis when so requested by medical practitioners or by the relatives.
4. That the medical officer of health insert the sum of £25 in the annual health department estimates to cover the expenses in connexion with the obtaining of weekly returns of sickness from all the friendly and sick societies in the borough, and that he formulate at an early date a scheme for obtaining these from the various secretaries and submit it to the health committee.
5. That the medical officer of health draw up a simply worded handbill on the prevention of tuberculosis and have this printed and circulated to every house in the town.
6. That the town clerk and the medical officer of health write to the Local Government Board asking that the New Dairies', Cowsheds', and Milkshops' Regulations framed by the Council should be forwarded as early as possible, otherwise farmers and others concerned would not be able to carry out any necessary alterations at a suitable time.
7. That the Royal Agricultural Society be accorded the best thanks of the committee for their kindness in forwarding copies of leaflets on tuberculosis in dairy stock, and that the medical officer of health circulate these to every cow-keeper within or around the district.

Plymouth.

A public meeting was held in St. Andrew's Hall, Plymouth, on Feb. 21st to form a branch for Devon and Cornwall of the National Association for the Prevention of Consumption. The Earl of Mount Edgecumbe was in the chair and Dr. Theodore Williams and Dr. Childs were present from London as representing the association.—The CHAIRMAN spoke of the formation of the association and pointed out that the association in no way desired to exercise any compulsion.—Mr. PAUL SWAIN in a very excellent speech pointed out that in his opinion the sanitary authorities would have to take the same steps for the prevention of consumption as they did for the prevention of scarlet fever and small-pox. The conscientious objector would of course be to the fore but for all that he hoped that the people of Devon and Cornwall would join the society in large numbers.—Dr. CHILDS emphasised the fact that consumption was a national and not a merely local question.—The resolution moved by the Mayor of DEVONPORT expressing the desirability of forming a branch of the association and inviting all present to form a general committee for furthering this object was carried unanimously. An executive committee was also formed. The secretary of the meeting to whose hard work and organisation much of its success was due was Dr. Frank Bushnell.

Cardiff.

On Feb. 28th the Health Committee of the Cardiff Corporation received a deputation from the Cardiff Medical Society with the view of inducing the Council to take measures for the prevention of tuberculosis. The President, Dr. Rhys Griffiths, Dr. Paterson, the Secretary, and Dr. Fiddian, the treasurer, addressed the committee at length. It was agreed to have a series of special meetings to discuss the matter. The medical officer of health, Dr. Walford, has sent in a special report dealing with tuberculosis.

The Cape.

A movement is on foot for the better prevention of tuberculosis upon board ship, especially upon the Cape steamers. We learn from *South Africa* of March 4th that a proposal has been made to run a line of hospital ships for "consumptives" to the Cape where they would be entertained at a receiving house until well enough to look for work.

(To be continued.)

SIXTH INTERNATIONAL OTOLOGICAL CONGRESS, 1899.

THIS Congress is to be held in London from August 8th to 12th, under the presidency of Dr. Urban Pritchard. The British Organisation Committee which numbers over 70 members from Great Britain and the Colonies has Mr. A. E. Cumberbatch for its treasurer and Mr. Cresswell Baber for secretary-general. The meetings will be held at the Examination Hall of the Royal College of Physicians of London and Royal College of Surgeons of England. On Monday evening, August 7th, a preliminary reception will be held by the president elect. The official languages of the Congress will be English, French, German, and Italian. The subscription, to include a copy of the transactions, is fixed at £1, to be paid to the treasurer, Mr. A. E. Cumberbatch, 80, Portland-place, London, W., before the opening of the Congress. The subject chosen for special discussion is "Indications for opening the Mastoid in Chronic Suppurative Otitis Media," which will be introduced by Professor W. Macewen of Glasgow, Dr. H. Knapp of New York, Dr. Luc of Paris, and Professor Politzer of Vienna. A museum of specimens and instruments relating to otology, shown by members, will be held during the meeting. Communications regarding the museum should be addressed to Mr. A. H. Cheatle, 117, Harley-street, London, W. Intending members of the Congress are requested to send in their names to the honorary secretary-general as soon as possible and in any case not later than May 1st. Titles of communications, together with a short abstract of the same, should be sent to the honorary secretary-general by the same date. According to the regulations of the Congress no papers shall exceed 15 minutes in reading; therefore all long communications should be read in abstract.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6540 births and 4853 deaths were registered during the week ending March 11th The annual rate of mortality in these towns, which had increased in the three preceding weeks from 19·5 to 21·6 per 1000, further rose last week to 22·2. In London the rate was 22·4 per 1000, while it averaged 22·0 in the 32 provincial towns. The lowest death-rates in these towns were 13·5 in Cardiff, 13·7 in Gateshead, 16·3 in Croydon, and 16·6 in Swansea; the highest rates were 28·0 in Manchester, 29·7 in Preston, 29·8 in Oldham, and 30·4 in Halifax. The 4853 deaths in these towns included 409 which were referred to the principal zymotic diseases, against 364 and 437 in the two preceding weeks; of these 114 resulted from measles, 111 from whooping-cough, 90 from diphtheria, 43 from diarrhœa, 32 from scarlet fever, and 22 from "fever" (principally enteric). No death from any of these diseases occurred last week in Croydon or in Burnley; in the other towns they caused the lowest death-rates in Norwich, Gateshead, and Wolverhampton, and the highest rates in West Ham, Birkenhead, Manchester, and Salford. The greatest mortality from measles occurred in West Ham, Derby, Bolton, and Manchester; scarlet fever in Derby and Salford; and whooping-cough in Plymouth, Birkenhead, Preston, Halifax, and Hull. The mortality from "fever" showed no marked excess in any of the large towns. The 90 deaths from diphtheria included 36 in London, seven in Sheffield, five in Leicester, five in Leeds, four in Cardiff, four in Liverpool, and three each in West Ham, Portsmouth, Swansea, and Salford. No fatal case of small-pox was registered last week in any of the 33 large towns; and two small-pox patients were under treatment in the Metropolitan Asylums Hospitals on Saturday last, March 11th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 2540, against 2575 and 2584 on the two preceding Saturdays; 217 new cases were admitted during the week, against 202, 241, and 236 in the two preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 484 and 470 in the two preceding weeks, rose again last week to 529, but were 29 below the corrected average The causes of 65, or 1·3 per cent, of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Salford, Leeds, Newcastle-upon-Tyne, and in 11 other smaller towns; the largest proportions of uncertified deaths were registered in Leicester, Liverpool, Blackburn, Halifax, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 24·1 and 25·1 per 1000 in the two preceding weeks, declined to 22·8 during the week ending March 11th, but exceeded by 0·6 per 1000 the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 10·2 in Perth and 18·9 in Dundee to 25·5 in Leith and 28·4 in Aberdeen. The 697 deaths in these towns included 30 which were referred to whooping-cough, 13 to measles, 11 to diarrhœa, five to scarlet to fever, four to diphtheria, and four to "fever." In all, 67 deaths resulted from these principal zymotic diseases, against 64 and 99 in the two preceding weeks. These 67 deaths were equal to an annual rate of 2·2 per 1000, which was slightly above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had been 23 and 31 in the two preceding weeks, were 30 last week, of which 11 occurred in Glasgow, eight in Edinburgh, and seven in Leith. The 13 deaths from measles showed a decline of 20 from the number recorded in the preceding week and included seven in Aberdeen. The five fatal cases of scarlet fever corresponded with the number registered in each of the two preceding weeks and included two in Glasgow and two in Dundee. The deaths referred to different forms of "fever," which had been four and six in the two preceding weeks, declined again to four last week, of which three occurred in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 233 and 213 in the two preceding weeks, further declined to 172 last week, and were 15 below the number in the corresponding period of last year. The causes of 33, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased in the three preceding weeks from 27·3 to 31·9 per 1000, declined again to 28·5 during the week ending March 11th. During the past four weeks the rate of mortality in the city has averaged 29·5 per 1000, the rate during the same period being 21·3 in London and 24·9 in Edinburgh. The 191 deaths registered in Dublin during the week under notice showed a decline of 23 from the number in the preceding week, and included 14 which were referred to the principal zymotic diseases, against 12 and 17 in the two preceding weeks; of these, six resulted from "fever," five from whooping-cough, two from diarrhœa, and one from diphtheria, but not one either from small-pox, measles, or scarlet fever. These 14 deaths were equal to an annual rate of 2·1 per 1000, the zymotic death-rate during the same period being 1.8 in London and 2·3 in Edinburgh. The deaths referred to different forms of "fever" which had increased from two to six in the three preceding weeks were again six last week. The fatal cases of whooping-cough which had been two and five in the two preceding weeks were again five last week. The two deaths from diarrhœa also corresponded with the number recorded in the preceding week. The 191 deaths in Dublin last week included 31 of infants under one year of age and 55 of persons aged upwards of 60 years; the deaths of infants showed an increase, while those of elderly persons corresponded with the number recorded in the preceding week. Seven inquest cases and six deaths from violence were registered; and 66, or more than a third, of the deaths occurred in public institutions. The causes of 12, or more than 6 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING FEBRUARY, 1899.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality during February in each of the 43 sanitary areas of London. With regard to the notified cases of infectious diseases in the metropolis, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 8·5 per 1000 of the population, estimated at 4,546,752 persons in the middle of this year. In the three preceding months the rates had been 10·8, 9·5, and 9·2 per 1000 respectively. The rates were considerably below the average in Kensington, Westminster, St. James Westminster, Marylebone, Hampstead, St. Martin-in-the-Fields, and Strand; while they showed the largest excess in Fulham, London City, St. Saviour Southwark, Rotherhithe, Woolwich, Lee, and Plumstead sanitary areas. No case of small-pox was notified in London during February, and only two cases of this disease were under treatment in the Metropolitan Asylums Hospitals at the end of last month. The prevalence of scarlet fever in London showed a slight decline from that recorded in the preceding month; among the various sanitary areas this disease showed the

* Including 34 cases of membranous croup.

† Including deaths from membranous croup.

highest proportional prevalence in Hammersmith Fulham, Rotherhithe, Greenwich Woolwich Lee and Plumstead The Metropolitan Asylums Hospitals contained 2535 scarlet fever patients at the end of February, against 3090, 2883 and 2637 at the end of the three preceding months, the weekly admissions averaged 236, against 239 in each of the two preceding months The prevalence of diphtheria in London during February differed but slightly from that recorded in the preceding month, this disease was proportionally most prevalent in Fulham Chelsea St Saviour Southwark, St George Southwark, Newington Bermondsey, Battersea and Lewisham sanitary areas There were 1338 diphtheria patients under treatment in the Metropolitan Asylums Hospitals at the end of February, against 1269, 1239 and 1358 at the end of the three preceding months, the weekly admissions averaged 172 against 173 and 166 in the two preceding months The prevalence of enteric fever in London showed a slight further decline from that recorded in recent months, among the various sanitary areas this disease showed the highest proportional prevalence in St James Westminster, Holborn, London City, Limehouse St George Southwark and Bermondsey The Metropolitan Asylums Hospitals contained 215 enteric fever patients at the end of February, against 286 255 and 249 at the end of the three preceding months the weekly admissions averaged 27, against 45, 36 and 34 in the three preceding months Erysipelas was proportionally most prevalent in Holborn St Luke Bethnal Green St George in the East Limehouse and Rotherhithe sanitary areas The 23 cases of puerperal fever notified in London during February included five in Hackney, three in Fulham, and two each in Bethnal Green Mile End Old Town, and Wandsworth sanitary areas

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided During the four weeks ending Saturday, Febr 25th the deaths of 7086 persons belonging to London were registered equal to an annual rate of 20 3 per 1000, against 16 3 16 9 and 17 0 in the three preceding months The lowest death rates in the various sanitary areas were 6 1 in Stoke Newington 10 6 in Plumstead 11 7 in Hampstead 12 9 in St Martin in the Fields 13 6 in Lee, and 13 9 in Lewisham (excluding Penge), the highest rates were 27 1 in St George in the-East 28 1 in St James Westminster 28·2 in Clerkenwell, 28 3 in Strand 29 4 in St Luke and St Olave Southwark 30 8 in Holborn and 32 9 in St George Southwark During the four weeks of February 567 deaths were referred to the principal zymotic diseases in London, of these 102 resulted from measles, 26 from scarlet fever 149 from diphtheria 188 from whooping cough 2 from typhus fever, 56 from enteric fever, and 44 from diarrhœa, but not one either from small pox or from any ill defined form of continued fever These 567 deaths were equal to an annual rate of 1 6 per 1000 against 1 7 and 1 5 in the two preceding months No death from any of these zymotic diseases was recorded last month in Strand sanitary area, in the other sanitary areas they caused the lowest death rates in Westminster, Hampstead Stoke Newington and Plumstead, and the highest rates in Holborn Clerkenwell, London City, Limehouse St Saviour Southwark, St George Southwark Newington Bermondsey and Lee The 102 fatal cases of measles were 69 below the corrected average number in the corresponding periods of the 10 preceding years, this disease showed the highest proportional fatality in St Pancras Clerkenwell Bethnal Green, Limehouse and Lee sanitary areas The 26 deaths referred to scarlet fever were less than half the corrected average number, among the various sanitary areas this disease was proportionally most fatal in Fulham and Lee The 149 fatal cases of diphtheria were 18 below the corrected average number, this disease showed the highest proportional fatality in Kensington Fulham Hackney Holborn Limehouse St Saviour Southwark St George Southwark Newington and Bermondsey sanitary areas The 188 deaths from whooping cough were 65 below the corrected average number, among the various sanitary areas this disease was proportionally most fatal in Paddington Chelsea Holborn St George in the East St George Southwark, and Newington Of the two fatal cases of typhus fever one belonged to Bermondsey and one to Rotherhithe sanitary areas The 56 deaths from enteric fever were 25 below the corrected average number, this disease showed the highest proportional fatality in St. Giles and Bermondsey sanitary areas The 44 fatal cases of diarrhœa were 11 below the average In conclusion, it may be stated that the aggregate mortality in London last month from these principal zymotic diseases was nearly 24 per cent below the average

Infant mortality in London during February, measured by the proportion of deaths of children under one year of age to registered births, was equal to 129 per 1000 Among the various sanitary areas the lowest rates of infant mortality were recorded in Hampstead Stoke Newington, Hackney, St Giles, Lewisham, and Lee, and the highest rates in Westminster, St Martin in the Fields Holborn Limehouse, St Saviour Southwark, and St George Southwark

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

THE following appointments are announced -Staff Surgeons O W Sharples to the *Monarch*, for Ascension Hospital, H Holyoake to the *Australia*, W M Craig to Plymouth Hospital, A S Nance to the *Galatea*, H E Iliewicz to the *Pembroke* and G T Collingwood to the *Hotspur* Surgeons M J O Regan to Bermuda Hospital, S Roach to the *Alert*, E Arkwright to the *Renown*, for the *Columbine* F Folliott to the *Eclipse*, for disposal, B Ley to the *Assaye*, W S H Sequeira to the *Lapwing*, H A Julius to the *Sphinx*, J H Acheson to the *Victory*, for disposal, W H O Garde to the *Victory*, for the *Research*, J G Watt to the *Wildfire* for the *Triton*, J H Pead to the Royal Marine Artillery Eastney O Rees to the *Wildfire*, for the Depôt Walmer, A G Eastment to the *Jason* E Bradshaw to the *Howe*, and I D Lumley to Haulbowline Hospital

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel R Drury and Captain D J Collins have been granted six months leave out of India on medical certificate Colonel E Townsend has been granted leave from India to England for eight months Major Butt will shortly embark for service in India Captain C B Lawson is posted to the Western Heights Dover for duty Major Henry J McLaughlin from half pay, to be Major, with precedence next below D F Franklin vice J R Barefoot deceased

ARMY MEDICAL RESERVE OF OFFICERS

Surgeon Lieutenant H C Reid to be Surgeon Captain

MILITIA MEDICAL STAFF CORPS

Surgeon Captain T W Richardson to be Surgeon Major, Surgeon Major T W Richardson resigns his commission, also is permitted to retain his rank, and to wear the prescribed uniform on his retirement Supernumerary Surgeon Lieutenant S Oliver to be Surgeon Lieutenant within the establishment

VOLUNTEER CORPS

Artillery 1st Argyll and Bute Surgeon Lieutenant D J Penney to be Surgeon Captain *Rifle* 1st Volunteer Battalion the Royal Welsh Fusiliers Surgeon Lieutenant T G Jenkins resigns his commission 1st Volunteer Battalion the Sherwood Foresters (Derbyshire Regiment) Surgeon Lieutenant R A Johnston to be Surgeon Captain 1st (Renfrewshire) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders) Surgeon Lieutenant A Leitch to be Surgeon Captain 1st Dumbartonshire James Reid Foulds to be Surgeon Lieutenant

THE ARMY ESTIMATES DEBATE

In the discussions which have been taking place in the House of Commons on going into Committee of Supply on the Army Estimates attention has been directed to the deplorable falling off in the physique of the general population revealed by the returns for recruiting Among the indications of the lowered health and physique of that portion of the population from which army recruits are mainly drawn Mr Wyndham in his speech on the Army Estimates referred to the number of would be recruits who were rejected on the ground of bad teeth and suggested that in elementary schools supported by public funds it might be possible to teach the pupils to take elementary precautions for the preservation of their teeth Without entering upon the causes neck, the latter being about twice its usual circumference, which had commenced only six months before although there was a history of long previous illness. It is mentioned as a striking feature in the case that it was complicated with stomatitis and copious salivation, against which all therapeutic means proved unavailing. The entire mucous membrane of the lips and mouth was red and swollen with numerous and ever-extending erosions and the inflammation ultimately invaded the pharynx and parts beyond. The patient hawked incessantly, but could not expectorate the accumulating secretion and he died from suffocation, the trachea and bronchi being found post mortem to be filled up with tough mucus. The case was during life regarded as one of elephantiasis and it was not until an article by Virchow on Myxœdema was published in the *Wochenschrift* of the same year, in which this case is recorded (p. 120) that Dr. Zielewicz recognised that he had had an example of the latter under observation.

I am, Sirs, yours faithfully,

Glasgow, March 6th, 1899. ROBERT KIRK, M.D. Edin.

"A CASE OF VOMITING LARGE MASSES OF CANCEROUS MATTER."

To the Editors of THE LANCET.

SIRS,—As you mentioned in one of your annotations in your issue of March 11th the case of vomiting cancerous matter published in THE LANCET of Oct. 3rd, 1896, I was induced to call at the patient's house to see if the patient was still in the land of the living and I was glad to find him this noonday engaged in eating and enjoying a good substantial dinner of meat and vegetables. He suffers occasionally from flatulent indigestion and about seven weeks ago he vomited some blood, but in other respects he feels very well. The blood came up so easily he does not think there was any cancerous matter in it; besides, at the time when the vomiting took place he was at work, and he says he was in his usual working health.

I am, Sirs, yours faithfully,

Lincoln, March 13th, 1899. WILLIAM O'NEILL, M.D. Aberd.

"INSTRUCTION IN ANÆSTHETICS."

To the Editors of THE LANCET.

SIRS,—I should like to be permitted to thank Dr. White for his letter on the above subject in THE LANCET of Feb. 18th. His views on the matter entirely coincide with those which I have long held and which I expressed in detail in a paper read before the Thames Valley Branch of the British Medical Association on March 16th, 1892, and published in THE LANCET of May 28th of the same year. Since the publication of that paper I have been personally responsible for the introduction of systematic instruction in anæsthetics on the lines advocated in three of the London medical schools (Guy's, King's, and the Royal Free) and I have every reason to believe that the teaching has much improved at other places. At Guy's especially the teaching is particularly thorough and comprehensive, for I was able to take advantage of the coexistence of the Guy's Hospital Dental School to afford the student instruction in the administration of anæsthetics for dental purposes as well as for surgical cases. So far, however, but little if any success has attended the attempt to induce the General Medical Council or the examining bodies to make instruction in the subject compulsory. In my humble opinion, and apparently in the opinion of Dr. White, the matter is as well worthy of attention as the abstruse and difficult art of vaccination which is still a subject of special enactment.

I am, Sirs, yours faithfully,

Devonshire-street, W., March 13th, 1899. J. F. W. SILK.

THE NORWICH MEDICO-CHIRURGICAL SOCIETY AND THE NEW VACCINATION ACT.

To the Editors of THE LANCET.

SIRS,—At an ordinary meeting on March 7th of the above society the following resolution forwarded for consideration by the honorary secretary of the Liverpool Medical Institution was endorsed by the Norwich Medico-Chirurgical Society—viz.: "That the members of the Liverpool Medical Institution are of opinion that the Vaccination Act, 1898, was enacted in direct opposition to the findings of the Royal Commission and that the operation of the Act will be prejudicial to the public safety and that its amendment is urgently required." It was also resolved to send a copy of this resolution to the Members of Parliament for this city and the county of Norfolk.

I am, Sirs, yours faithfully,

Norwich, March 11th, 1899. H. C. NANCE, Hon. Sec.

THE GENERAL MEDICAL COUNCIL AND THE MIDWIVES QUESTION.

To the Editors of THE LANCET.

SIRS,—In a leading article in THE LANCET of March 11th I note a statement to the effect that the General Medical Council had postponed the consideration of the question of the subject of granting illegal certificates of proficiency in medicine, surgery, and midwifery. The profession has always suffered from this fatal fault of procrastination on the part of its governing authorities with the result in this case of the country being flooded with all sorts of persons, male and female, who practise small portions of the profession of medicine. These persons are possessed of certificates signed in some cases by members of the profession and in others signed by persons other than those on the Register of medical practitioners.

It is quite clear that the General Medical Council can deal with those members of the profession who sign certificates which are used for the purposes of medical practice and it is their duty to do so. No doubt the certificates are often granted in the first instance for legitimate purposes, but in too many cases the certificates are used for purposes which the signatories did not originally intend. The practical point which I wish to urge is this—that the General Medical Council should issue a notice to the medical profession that in future it will hold the signatories of such documents responsible for the misuse of certificates of proficiency signed by them or issued by their authority. If the Council will take some such step as this we shall, I am confident, see an end of the nurse, the midwife, the masseuse, the oculist, *et hoc genus omne*, as practitioners of medicine. The fault lies at the door of the profession and not at that of the community. It is amusing to contrast the stringency with which penal enactments are enforced against the little men of the profession who are not allowed representation except in a most limited manner and the leniency with which the men who are in touch with the great corporations are treated, and it will be a comfort to see a little reform in the central machinery which is the real spot to be touched.

I am, Sirs, your obedient servant,

Hatfield, Herts, March 12th, 1899. LOVELL DRAGE.

"DIFFICULTIES UNDER THE NEW VACCINATION ACT."

To the Editors of THE LANCET.

SIRS,—I think it is the duty of the family medical practitioner to attend to the vaccination of his patients and many men after returning from a confinement make a practice of entering the infant's name for vaccination purposes in their visiting lists which also generally contain some special columns for that purpose. Surely it is not touting to care for and visit one's own patients when necessary. In matters of medical interest I question if it is not always the duty of the family practitioner to try to safeguard his patient and it is by no means the rule to act as "General Practitioner" thinks. As regards your correspondent's letter signed "P. P.," if your readers will kindly refer to THE LANCET of March 4th they will see that I am misquoted.

I am, Sirs, yours faithfully,

March 12th, 1899. FAIRPLAY.

To the Editors of THE LANCET.

SIRS,—May I point out that in Form H the name and address of the child only is given and when we proceed to send out Form I we do not know to whom to address it?

In a country parish where many different families of the same name reside and in which the only address can be the of the parish, the houses being unnumbered, I fail to ow the notice can be delivered to the right person. It ought to have a column with the name of the or guardian of the child to whom the notice could be

I am, Sirs, yours faithfully,
T. Woods,
Public Vaccinator.

ngham, Dorset.

.—It may be useful to many of your readers to know the vaccine lymph from a capillary tube can be easily safely ejected upon the point of the lancet or other ament by breaking off one end and holding the other in ame of a spirit lamp, thus doing away with the "lymph or."

SALIPYRIN IN INFLUENZA.

To the Editors of The Lancet.

ns,—As far as I can gather this drug appears to be but e known and less used in this country. In Germany its ific action in influenza has already been widely reco- ed. During the present epidemic I have used salipyrin largely and my experience has been such that I think a rapeutic note is justified in The Lancet. Given in a mild e early enough the disease is cut short in a few hours; in at would be a severe case the pain is quickly removed, the perature falls gradually, and, what is most important, re is no collapse, depression, or cardiac weakness from action of the drug. Salipyrin is a salicylate of antipyrin d is supposed to break up in the alimentary canal into icylic acid and antipyrin. It does not appear, however, t the depressing effects of antipyrin are manifested where ipyrin is used; the action seems to be chiefly antiseptic d anti-malarial. I have given it in three-grain tabloids, om three to six grains every three hours, according to the verity of the case.

I am, Sirs, yours faithfully,
A. Butler Harris, M.A., M.B., B.Ch. Oxon.

Loughton, Essex, March 13th, 1899.

HE MIDWIVES' INSTITUTE AND THE BILL FOR THE REGISTRATION OF MIDWIVES.

To the Editors of The Lancet.

Sirs,—The enclosed letter is being laid before the Midwives Bill Committee by the Incorporated Midwives' nstitute.

I am, Sirs, yours faithfully,
Rosalind Paget.

12, Buckingham-street, Strand, W.C., March 14th, 1899

[Inclosure.]

12, Buckingham street, W.C., March 14th, 1899.

To the Chairman of the Midwives' Bill Committee.

Sir,—The Council of the Incorporated Midwives' Institute, after a conference with their members, have requested me as their representative to lay before your committee their views on the present Bill.

The Council of the Incorporated Midwives' Institute consider this Bill inferior to that of last year, but they are, however, so strongly impressed with the urgent need for legislation that they will offer no opposition to the present Bill so long as the following points are insisted on.

1. That the final decision in all cases be in the hands of the central authority (see clause 9, Duties of Supervising Authority, and clause 10, Annual and Local Certificate). They consider with regard to clause 10 that their interests are not sufficiently safeguarded.

2. That their representation on the central board is retained and that an amendment is asked for—"that the nominees of the Privy Council should be two lay persons, one a woman."

3. That the certificate of the London Obstetrical Society be retained as a qualification for licence.

Your committee will doubtless consider that these three points are some of them already dealt with in the Bill and that the others will follow as a natural sequence. The reason the council of the Institute have called your attention to them is because of the amendments to this Bill that have appeared in the *British Medical Journal*, and which will doubtless be largely supported by the medical profession.

The Council of the Incorporated Midwives' Institute consider the machinery of the new clauses to be so complicated that they will prove unworkable and provide only a "nominal" protection to the mother, and the "pretence" of a monopoly of practice to the licensed midwife. They consider the unconscientious midwife will have every opportunity of evading the law, while the conscientious midwife is controlled at every turn and might possibly fall a victim to local jealousy owing to the preponderance of medical representation on the Midwives Board. A further danger is created by the uncertainty regarding the official position of the person to be appointed as local supervising authority.

I remain, Sir, your obedient servant,
Rosalind Paget
Honorary Treasurer, Midwives' Institute, and Representative on the Midwives Bill Committee.

STOCKPORT CENTRE, ST. JOHN AMBULANCE ASSOCIATION.

To the Editors of The Lancet.

Sirs,—Referring to the recent public meeting of the above centre and on the strength of a garbled and one-sided account thereof in the *Stockport Advertiser*, you have seen fit in your issue of 18th inst. to direct certain strictures against members of the profession which you specially represent. In reliance upon your adherence to your motto "*Audi alteram partem*" copies of other newspaper reports are enclosed for your information, together with certain correspondence which may enlighten you as to the true facts. Your inference that it was insinuated that the local secretary of the St. John Ambulance Association was making a profit out of the association merely shows that the proverbial red herring has been drawn across the track. His discourteous attitude towards some members of the medical profession and others interested in ambulance work is the real cause of the present dissatisfaction. *Not only was no insinuation of dishonesty made but the suggestion was repeatedly repudiated.*

Your remark that a public meeting is not the best place for inquiry into such matters represents the view taken by the Medical Society who decided that the local St. John secretary was not to be attacked unless he first assailed the Medical Society or one of its members. This he at once did and was attacked in turn.

I accept the entire responsibility for the statements in this letter, which I request you to publish in fairness to the medical men concerned.

I am, Sirs, yours faithfully,
O. Porter.

Victoria-park, Stockport, Feb. 26th, 1899.

"THE TALLERMAN TREATMENT AND ITS COUNTERFEITS."

To the Editors of The Lancet.

Sirs,—Will you allow me to correct an impression that has been formed through the misleading statements in the press that the Tallerman apparatus is heated by gas only? That apparatus is heated equally well with any heating agent—electricity, gas, or oil—and can therefore be taken anywhere and used with any heating agent available. The first two are in use at the company's institute at Welbeck-street. The Greville electric apparatus is, in which view I am supported by two well-known medical men, the same as an old electric heating apparatus that has been standing in this institute for over three years and was originally surrendered to this company as an imitation by a medical man who accompanied the surrender with a letter binding himself not to infringe the company's rights in a similar manner again.

The introduction by members of the medical profession of this apparatus and others of a similar nature in order to counterfeit the Tallerman treatment by the local application of dry air heated to high temperatures is, having regard to all the circumstances, indefensible, whilst the attempt to deprive me of the credit of inventing this new treatment by writing about the Greville "system" and "method" is an attempt to justify a line of action which, to my way of thinking, is neither in accordance with professional ethics nor in the interests of the profession.

I am, Sirs, yours faithfully,
Lewis A. Tallerman.

Welbeck-street, Cavendish-square, W.,
March 13th, 1899.

Assault on a Public Vaccinator at Yeovil.—At the Borough Petty Sessions held at Yeovil on March 7th a school attendance officer was charged with assaulting Mr. C. J. Marsh, M.R.C.S. Eng., L.R.C.P. Edin., public vaccinator for the Yeovil Union. Evidence showed that Mr. Marsh called upon defendant in reference to the vaccination of his child and asked him whether he would have it vaccinated or not. The defendant declined to answer the question and became abusive to Mr. Marsh and finally told him to go down the steps, pushing him on the shoulder. The bench of magistrates unanimously fined the defendant 5*s*.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Royal Medical Society.

ON the evening of Friday, March 10th, the annual dinner of the Royal Medical Society was held in the University Union, when about 80 gentlemen dined together. The guest of the evening was Sir William Overend Priestley, M.P., who, in replying to the toast of his health, said that he was quite in agreement with the society in his affection for the University of Edinburgh. He regarded himself as owing everything to Edinburgh University and to Edinburgh itself. He not only owed his education to the University of Edinburgh, but from Edinburgh he carried away a wife with whom he had lived in unclouded happiness for between 40 and 50 years; and, to crown all, the University of Edinburgh had conferred upon him the greatest happiness of his life by making him its representative in Parliament. Since the time when he was a student in the University great changes had come over the place. The whole of their educational facilities were then confined to the quadrangle of the Old University, but since then the new University buildings had sprung up as well as the magnificent new Medical School, the Union in which they were assembled, and the M'Ewan Hall, in which the great celebrations of the University were held. He had the privilege of studying at a time when there was in the University a company of professors such as had never previously been equalled and which perhaps would never be equalled again—Alison, Robert Christison, James Syme, James Young Simpson, Hughes Bennett, Goodsir, William Hamilton, Aytoun, Christopher North, Gregory, and Pillans. He thought that the teaching of Edinburgh University was a model for all other universities in the world. In the University of London, for instance, a pupil might get his education anywhere and simply present himself for his examination, but a university conducted on these lines could be none other than a stepmother to a man; in Edinburgh they had a real *alma mater*. He need not tell a meeting composed so largely of medical men how noble was the profession which they had chosen. It was one which satisfied all the aspirations of an honourable man, and when men settled down to practise, they ought to regard their profession from its higher aspects and look upon the public good as their foremost object. Sir William Gairdner, replying to the toast of "The Scottish Universities," said that these universities had of late been passing through a critical period of their existence. They had been the subject of a very long inquiry held by a Royal Commission and certain changes had been introduced. He had misgivings about these changes in some respects, but on the whole he was prepared to admit that the Commission had done its best, and he trusted that the result would be the placing of the Scottish Universities in a still stronger position than they had hitherto occupied. Though a professor in Glasgow University he was an Edinburgh man. He sincerely hoped that the University of Edinburgh would long maintain its great reputation. In his subsequent remarks Sir William Gairdner spoke of the great change which had come over the system of medical teaching and practice since his student days. Sir William Priestley, in proposing the toast of "The Royal Medical Society," observed that it compared very favourably with the debating societies or unions of Oxford and Cambridge, and that it performed a most useful function not only in exercising its members in the subjects which they were taught, but in training them to be debaters.

University of Aberdeen.

The interesting and valuable museum of Egyptian antiquities collected by the late Dr. James Grant (Bey), A.M., M.D., LL.D. Aberd., and presented by his widow to the University, was formally opened on March 11th, all the articles having been efficiently arranged at King's College together with other curios and antiquities there. An "At Home" was given by Principal Sir W. D. Geddes and Lady Geddes on the occasion.

Measles in Aberdeen.

This epidemic is now declining, the number of new cases reported for the week ending March 11th being 488, as compared with 630 and 602 respectively for the two previous weeks. During the month of February 33, or 12·7 per cent., of the deaths in Aberdeen were due to measles.

Aberdeen District Nursing Association.

During last year 984 of the sick poor were attended to at their own homes, being 196 more than in the previous year.

March 15th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

National Hospital for Consumption for Ireland.

THE annual meeting of the supporters of the National Hospital for Consumption for Ireland, situated at Newcastle, county Wicklow, was held at 6, Stephen's-green, on March 13th. The President of the Royal College of Physicians of Ireland, in moving the adoption of the report, suggested that the attention of Her Majesty the Queen might be called to the advantage which would accrue to the hospital if she was pleased to extend her Royal patronage to it and to confer on it the title of "Royal." The Registrar-General, in seconding the motion, said that the great thing at present was to convince the public that consumption was preventable and curable. If that was done there would be no difficulty in obtaining the necessary funds for a considerable addition to the hospital.

The City of Dublin Hospital.

At the last fortnightly meeting of the Pembroke Urban District Council a letter was read from the directors of the City of Dublin Hospital asking for an increase in the grant to that institution and pointing out that a considerable proportion of the patients came, not from Dublin, but from the Pembroke township. Dr. Cranny proposed that the annual grant should be increased and it was ultimately raised from £100 to £200. There always seemed something Irish and odd about the title "City of Dublin" being applied to the only one of the Dublin hospitals situated outside the city, but the founders of the institution prove to have been wise in their generation and the hospital is now in receipt of an annual grant of £400 from the city corporation and an additional £200 from the Pembroke township.

Death of Mr. M. A. Boyd, M.D. Brux., F.R.C.P., F.R.C.S. Irel.

The death of one of the best known and most highly esteemed of the physicians of Dublin, Dr. M. A. Boyd, took place on March 5th. The deceased who was aged fifty years was apparently in his usual perfect health and was seeing after his patients up to the evening of Monday, Feb. 27th, when he was suddenly attacked with acute pleuro-pneumonia, which proved fatal on the following Sunday. He was for many years one of the physicians to the Mater Misericordiæ Hospital, Dublin; consulting physician to St. Michael's Hospital, Kingston, and to the National Lying-in Hospital. He was the author of many able contributions to the Transactions of the Royal Academy of Medicine of Ireland. Outside the ranks of his profession Dr. Boyd was widely known and exceedingly popular. He was a member of the Royal Irish Academy, as well as of many art societies, where his annual exhibits of clever water-colour sketches taken during his summer holidays will long be missed. He was a popular member of the Ward hunt and, in fact, was out hunting with that famous pack of hounds two days before the commencement of his fatal illness. The sympathy of all classes in Dublin was roused by the pathetic circumstances that the deceased's mother, to whom he had been much devoted and who had been in failing health for some months, succumbed to the shock of her son's death and died a few hours after him. The double funeral which took place on March 4th was very largely attended, the students of the Mater Misericordiæ Hospital being represented by a contingent of over 100 who joined the cortège as it passed in front of the hospital on its way to Glasnevin.

Rotunda Hospital, Dublin.

At a meeting of the governors of the Rotunda Hospital, which took place on March 10th, attention was called to an interesting improvement which the Master is about to introduce in supplying the operation theatre with sterilised air.

Royal Army Medical Corps.

The Secretary of State for War has requested the Royal College of Surgeons in Ireland to nominate Licentiates of the College for commissions in the Royal Army Medical Corps.

Victoria Hospital for Diseases of the Nervous System, Belfast.

At the second annual meeting of the supporters of this hospital, held on March 9th, it was reported that during the year 246 patients had received treatment. The receipts from all sources were £356 4*s.* 6½*d.* and the expenditure had been £224 16*s.* 5*d.*

The Election of Poor-law Guardians.

The annual election of Poor-law guardians for the Belfast Union is shortly to take place and it is interesting to note that there are nine lady candidates, the largest number who have ever come forward. The general feeling in the city is that it would be most desirable that lady guardians should be elected. The Poor-law system in Ireland is in a deplorable condition, the problem of what to do with able-bodied paupers and the question of the great importance of separating young children from associating with the workhouse, either by the establishment of cottage hospitals or boarding-out, demanding the most careful consideration. The feeling is growing stronger that in many questions to be dealt with under the Poor-law system the presence of suitable lady guardians would be of enormous value at the boards.

March 15th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A New Chair of Gynæcology.

ON Feb. 27th the Chamber of Deputies refused a recommendation of the Committee of Supply with reference to a vote of credit of 18,200 francs for a new chair of Clinical Gynæcology at the Paris Faculty of Medicine. This chair will, however, after all be shortly founded, thanks to the concurrence in the scheme of the municipal council. A committee nominated by the town and the University of Paris met recently and decided unanimously to propose the creation not only of the chair of Gynæcology but also of one in the Clinical Surgery of Children. The candidates most widely spoken of for the chair of Gynæcology are MM. Pozzi, Bouilly, and Richelot. The last named is strongly supported by the municipal council and M. Pozzi who is a senator is the favoured ministerial candidate.

The Parasites of Cancer.

At the meeting of the Society of Biology held on March 4th Professor Curtis of Lille communicated the results of some researches which went to show that the results previously published for some time past upon the inoculable or cultivable parasites of cancer were invalidated by some error in the methods employed. Only recently M. Bra, following in the steps of many other experimenters, has described in great detail a micro-organism which he succeeded in cultivating and which in his opinion was the pathogenic germ of cancer. M. Curtis, however, declared that if one took every precaution to eliminate extraneous organisms and other sources of error neither culture nor inoculation results were obtained. For his own part he employed nothing but absolutely fresh tissues and of such only those which showed no ulceration and had not been accidentally infected. All operative measures must be carried out with speed and quite aseptically. The first condition to observe was to use the tumour tissue within a few minutes of its removal from the body and to take care that even during this short space of time the temperature of the fragment should be kept up. So as to avoid the danger of accidental infection M. Curtis never employed any growth showing the least sign of ulceration, for, to give an instance, in a cancer of the breast experimented on while still warm and which was slightly ulcerated he had found the bacillus coli together with the staphylococcus, both albus and aureus. Another point noticed was this—all new growths, even though not ulcerated, which have anything to do with mucous membrane are always infected with micro-organisms, while ulcerated growths of the vagina or uterus simply swarm with every kind of bacterium. M. Curtis, therefore, decided to use in his experiments no growths other than those of the testicle or the breast and these only when they were quite free from ulceration. It is necessary, according to M. Curtis, not to use any ulcerated growth, any growth springing from mucous membrane whether ulcerated or not, or any growth of any part of the alimentary canal or of the genital passages. All of these give rise to error from accidental infection. M. Curtis made his experiments as soon as possible after the removal of the growth from the body and the inoculations were finished within three-quarters of an hour. The fragment of cancerous tissue was taken from the middle of the growth by means of a specially constructed and carefully sterilised harpoon and inoculations were made sometimes in the peritoneal cavity, sometimes under the skin of the back, and sometimes at the junction of the limbs and the body. The animals used were dogs, rabbits, guinea-pigs, and white rats. Experiments were made with both solid tissue and triturated pulp. Bacteriological experiments were made every time with more than 12 different kinds of culture media, some solid, some liquid and representative of those most usually employed in laboratories. In 25 experiments, all conducted with extreme care, he obtained no definite result either when bacteriological cultivations were employed or by using inoculation experiments in animals. Fragments of tissue enveloped in collodion and placed in the peritoneal cavity of a rat gave a negative result. To sum up, M. Curtis considers that the epithelial cancer of man is neither inoculable nor cultivable by any means hitherto employed and that all observations tending to show the contrary which have been so far published are faulty owing to errors in technique.

Notes on News.

At the meeting of the Academy of Sciences held on Feb. 27th Professor Ray Lankester, whose works have a great reputation throughout France, was elected a Corresponding Foreign Member.

The census of persons practising medicine in France showed at the beginning of the year 1899 a number of 17,735, at the beginning of the year 1898 15,984, thus showing an increase for 1899 of 1751, a figure which is by no means what might have been expected when the very small increase in the general population is taken into existence and which augurs very badly for the future of the medical profession in France owing to the great decrease in disease thanks to the improvements in sanitation.

The Association for the Care of Tuberculous Children held its annual meeting on Feb. 25th, Dr. Herard, member of the Academy of Medicine, being in the chair. The treasurer in his report said that the association at the beginning of the year 1888 had only 12 beds; it now possesses two special hospitals at Armesson and Villiers with 350 beds and two convalescent homes at Noisy and Trémilly. The expenditure is 400,000 francs per annum. In 10 years the association has treated 9514 sick children, representing 326,859 days in hospital and 19,547 consultations. In the near future the convalescent homes will be increased to four in number and the children who have got well will be trained there to agricultural work and other out-of-door occupations which offer the best chance of a healthy future for them.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Criminal Anthropology: the Approaching Congress.

THE important debate in the Italian Chamber of Deputies on the Government Bill which has now passed the second reading on "Delinquenti Recidivi" (relapsing criminals) brought into salient relief the steady and sure, if slow, penetration of psychological medicine into what has hitherto been a "juridical preserve." "In Italy," said one of the speakers, "indeed in all other countries except England, crime shows a continuous increase as statistics dating from 1890 demonstrate." England, he proceeded to argue, maintains this honourable position because her legislature seriously and effectively takes note of the predisposing causes and the active incentives to crime and shapes its provisions accordingly. More than half a century ago Dr. Bruce Thomson of the Perth penitentiary insisted on the hereditary and self-evolving character of certain forms of criminality, deducing from his premisses the existence of a criminal class which must be broken up and dispersed or so separated from the conditions favourable to its reproduction as steadily to minimise its numbers and gradually to lose the inveteracy of its "criminal habit." These wise words are beginning to find an effective audience in Italy, where hitherto the "discord between the judiciary police (the 'magistratura giudicante') and the prison administration" has been a promoter and not a counter-agent of the prevailing criminality. But Italy, according to the same speaker, (the Hon. Enrico Ferri, *privat-docent* in Criminal Law and Administration in the University of Rome), must begin at an earlier stage than is necessary in England, Switzerland, or other nationalities economically more favoured. She possesses in numbers sufficient to form a substantive portion of her population a physically and morally degenerate type which, unless subjected in childhood or even infancy to countervailing conditions, reproduces itself with ever intensifying distinctness till there is engendered the "delinquente nato" (born criminal)—not the occasional offender, from whom society has nothing to fear, but the congenital and systematic delinquent who simply multiplies and becomes more dangerous under the merely repressive measures hitherto in practice. In this contention he had the support of other members of the Chamber, not those of medical training and profession merely, but barristers themselves and "publicists" or men of affairs. He was ably followed by Signor Ludovico Fulci who, while confirming the statement as to the increase of crime, denounced the prevailing penal system as feeding the malady it meant to destroy; and by Signor Venturi who agreed with Professor Ferri that "delinquenza è una malattia" (crime is a disease) in the class whose conditions the Chamber was considering—the "recidivi." I need not go into the minor details of the discussion—most interesting psychologically and socially as they often were—the uselessness or worse of deportation over sea, for instance, a system abandoned by all but France, or the utilisation of criminal hands in the reclamation of malarious localities, on which Signor Bonacci gave most instructive evidence, especially as to the employment of such labour by the Trappist Brothers of the Tre Fontane. Rather would I point out the significance of the whole debate in view of the International Congress of Criminal Anthropology to be held next August at the Hague, at which not a few of the members of the Italian Legislature will intervene and contribute to its discussion something more than the "vivacity" and the "theoretical dogmatism" which enlivened if it did not enlighten the Congress at Geneva in 1896. The triennium which has elapsed has been exceptionally full of incidents on which the criminal anthropologist can speak with relevance and authority—incidents which, like the organised political assassinations and the riots promoted under kindred auspices, have led to "Leagues against the Knife" and other palliative attempts culminating in the International Congress for the Repression of Anarchism which concluded its sittings in Rome just before Christmas. These "attempts," palliative or repressive, have been without medical inspiration or have partaken so little of the "medical mind" as to require all the supplementary and corrective handling which the Congress of Criminal Anthropology can so amply provide. The literature alone that has accumulated on the "genesis and conditions of crime, occasional or systematic, social or international," would of itself suffice to give directness and precision to the proceedings—literature in which pyschological medicine is largely and ably represented as well as advanced with an authority which neither jurist nor civil legislator can afford to ignore.

March 12th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

Plague in Jeddah.

BUBONIC plague has now made its appearance in Jeddah for the third time, some cases having been discovered on Feb. 22nd by Dr. Xanthopoulidis, sanitary medical officer of the town. Before formally notifying the fact he made a bacteriological examination and found the plague bacilli. He also prepared cultures and made inoculations so that the diagnosis was placed beyond doubt. Since the abovementioned date there have been six deaths from the disease. The Jeddah authorities assert that the houses in which these deaths occurred were not occupied by plague patients either during the present year or in the previous epidemics but it remains a question whether the said authorities had knowledge of all the houses in the town where plague cases existed. If in civilised countries the notification of zymotic diseases presents difficulties what may be expected of notification in Jeddah? In addition to the unwillingness of the inhabitants to give such information their religion forbids a woman's dead body to be exposed in sight of a man. In all probability there were many houses in Jeddah in which plague existed unknown to the local authorities. Last year after the departure of the pilgrims the Turkish authorities undertook the disinfection of Jeddah, and it was at first proposed to disinfect all the houses without any distinction, but in the result it was only the few houses in which plague was known to have occurred that were disinfected. The plague was not imported by the pilgrims who proceed to "Hedjaz" through Jeddah, for they undergo a ten-days' quarantine at the lazaretto of Camaran, where their belongings are thoughly disinfected. The disease was imported by "sanitary smuggling," which is rife on those shores of the Red Sea. The outbreak of plague in Jeddah at this moment acquires a great importance on account of the pilgrimage to the Mahommedan holy cities, Mecca and Medina. In the latter two cities no case of plague has been observed in the last two pilgrimages. It is to be hoped that the present year will be equally exempt, with which object in view the authorities of the "Hedjaz" are doing their best to prevent the spread of the epidemic and Dr. Cozzoni, Inspector of the International Sanitary Commission, is proceeding to Jeddah for the purpose of superintending the work. The measures adopted will be as follows: (1) the town of Jeddah with its surrounding villages will be isolated by a sanitary cordon; (2) the infected houses will also be isolated by a sanitary cordon, in addition to which the belongings of all plague patients will be burned, distilled water will be supplied for drinking purposes, and all the sanitary steps *decided on last year* will be put in operation; (3) the pilgrims who are at this moment at Jeddah will be removed to the island of Abas-Saad where they will await further instructions; (4) no pilgrims or passengers will be allowed to leave Jeddah for Mecca until buildings have been erected at Bab-el-Mecca (Mecca Gate), where they will undergo quarantine; (5) pilgrims arriving at Jeddah must land at a new wharf which is being constructed at a place six miles north of Jeddah; the pilgrims for Mecca will land there and proceed straight to Mecca without having any communication with Jeddah; and (6) in other ports of the Turkish empire arrivals from Jeddah will be subjected to 10 days' quarantine.

Small-pox and Influenza.

Small-pox has been excessively prevalent in Constantinople for some time now and is very fatal. The people disregard the law which makes vaccination compulsory, although the Government has given stringent orders that its provisions are to be carried into effect and no fees are charged. There is also a good deal of influenza, but not so much as in some other capitals. The deaths from influenza are not registered in the *Bulletin de la Mortalité* published every week by the sanitary board. Only the deaths from acute inflammation of the lungs are registered; the number of these deaths is about 50 per week.

Chemical Analysis in the Custom-house.

Many years ago the custom-house authorities seized a large quantity of quinidine imported as sulphate of quinine and it was then ordered that all samples of quinine should be analysed in the custom-house. In course of time other medicines were directed to be analysed and the system was at last extended to a variety of imported products, such as flour, wine, oil, soap, &c., which, unless they were of a quality satisfactory to the chemists, were not allowed to pass through the custom-house into the possession of the merchants. Large quantities of imported goods were declared by the chemists to be prejudicial to health, but the trading community was not of their opinion and after some difficulty it was arranged between the Government and the foreign representatives (embassies, legations, and consulates) that the custom-house analyses should be made in the presence of a chemist acting on behalf of the merchants. This checking of their methods by a foreigner was highly distasteful to the custom-house officials and has not prevented great quantities of goods being stored in the custom-house for many months, delivery to the merchants being refused on account of the alleged inferior quality of the articles. The officials wished to forbid the importation of American flour of the best quality, containing more than 15 per cent. of gluten, but the American consulate, supported by the American Legation protested vigorously and the flour has been delivered to the consignee. Merchants, who are not protected by legations as the Americans are, have to submit to the detention of goods, even of excellent quality, at the custom-house.

March 2nd.

Obituary.

SIR DOUGLAS GALTON, K.C.B., D.C.L., LL.D., F.R.S.

THE profession of medicine had not the honour of numbering the late Sir Douglas Galton among its members, but nevertheless many aims and objects were common to both. The occasion of the death of Sir Douglas Galton affords a fitting opportunity for us not only to put on record our sense of the loss which the public and the profession have sustained but to touch upon a few of the lessons to be derived from a scientific career and the application of high scientific attainments directed for the most part to purposes from which we all benefit but about which so few of us are mindful. Sir Douglas Galton was a many-sided man. His energy was great and the amount and varied nature of his work were remarkable. Railways, fortification, ordnance survey, submarine telegraphy, schemes for London sewage disposal, the designing of hospitals, the ventilation and warming of houses, and work in connexion with secretarial duties at the War Office, Her Majesty's Office of Works, the British Association for the Advancement of Science and the Royal Society made up his life-history. But it was his keen interest in all matters affecting public health and his practical knowledge and scientific attainments which made him an authority on hospital construction, sanitation, ventilation, and the hygienic management of public buildings. His main aim was to substitute scientific formulæ and deductions derived from experimental observations and accurate data for the rule-of-thumb laws and more or less vague generalisations on which systems of sanitation at one time rested and to put sanitation upon a scientific plane—in brief, to make a sanitary science properly so called. Of course he was neither the first nor was he alone in striving to do this, but he was nevertheless among the pioneers and he happily lived to see not only how much had been accomplished, but to realise how much more was really comprehended in sanitary science than was circumscribed within its merely apparent limits. As a lake or river often unexpectedly overflows its banks so does the rapid growth and increased application of a scientific branch of study sometimes overstep the limits of the terms in which it is expressed. If in this and other scientific work Sir Douglas Galton cannot be credited with many original investigations or discoveries he always maintained an appreciative mind for them. He at once recognised the importance of following and utilising nature's method in the biological system of treating sewage, for example. It is not easy to describe Sir Douglas Galton's career because of the number and variety of the posts which he occupied, but a mathematical turn of mind and a love of physical science formed the thread on which all his scientific studies and occupations were strung. Still, he was not by any means a mere foot-rule philosopher; the salt of humour flavoured his intellectual soil; he was eminently fair-minded, and a judicious and well-read, genial man. He was a Rugby boy at the time when Dr. Arnold made its reputation and his own and when the author of "Tom Brown's Schooldays" was gathering together the material and incidents for that work. He went to Woolwich and after a most distinguished and successful career passed out of the Royal Military Academy into the Royal Engineers. Among other things it may be mentioned that he was instrumental in getting the Barrack Works Committee of 1862 appointed by the then Secretary of State for War. This was not an altogether popular measure at the time, but it was the means of leading to great and beneficial changes, in that it fixed individual responsibility upon all those connected with the execution of public works. From the time of the Crimean War almost up to that of his death Sir Douglas Galton was keenly interested in all that related to army sanitation and practical hygiene and he did a great deal in common with Dr. John Sutherland, Sir Robert Rawlinson, Professor Parkes, and others to bring about the immense change which has taken place during the last 40 or 50 years, with what results may be more readily appreciated by the following contrast. In the report of the Royal Commission of 1858 it is stated that the rate of mortality in the army at home was 17·6 per 1000, whereas in 1897 it was only 3·42 per 1000, and the provision of hospital accommodation in our home garrisons, which was at the rate of 10 per cent. of the strength, has now, we believe, been reduced to six per cent. Turning to the European army in India the mortality rate prior to 1857 reached 69 per 1000, according to the report of the Royal Commission of 1863, whereas it was only 14·84 per 1000 in 1896 according to the report of the Sanitary Commissioner with the Government of India for that year. It cannot, of course, be claimed that these results are solely attributable to improved sanitation, for numerous other changes have taken place which have largely contributed to bring them about—in the way of short service, the better feeding, clothing, and equipment of soldiers, increased facilities for invaliding, and so forth. Still, improved sanitation and better barrack accommodation and other hygienic measures too numerous to mention are to be largely accredited with the vast change that has taken place. If we had to point to a practical illustration of the beneficial effect of measures of a purely sanitary kind we probably could not select a better one than the contrast between the prevalence of ophthalmia as it was in the army many years ago and as it is now. There was a time when ophthalmia was an army scourge. Soldiers in other respects healthy were to be found suffering from ophthalmia in most of our military hospitals at home and abroad and were constantly being invalided from that cause. In towns and villages there might be encountered discharged soldiers whose slow steps, shuffling gait, contracted brow, and watery eyes proclaimed the nature of their complaint. But better barracks and improved ventilation and lavatory arrangements have practically banished the military form of ophthalmia once so prevalent just as epidemics of typhus fever have ceased to appear in our midst. Sir Douglas Galton was a member of the Army Sanitary Committee from its beginning and was the possessor of numerous academical and scientific titles and distinctions. He was made F.R.S. in 1863, and became the President of the British Association for the Advancement of Science and delivered the presidential address in 1895, besides being a D.C.L. of Oxford and LL.D. of Durham and Montreal. He was made a K.C.B. in 1887.

FRANCIS NOTTIDGE MACNAMARA,

M.D. ST. AND., M.R.C.S. ENG.,

RETIRED SURGEON-MAJOR I.M.S.

DR. FRANCIS NOTTIDGE MACNAMARA, whose death occurred on the 5th of this month, as we have already reported in these columns, was a distinguished physician and sanitarian whose best work was done in India. He received his medical education at King's College, London, and in 1853 entered the Indian Medical Service. While quite a young man he was selected by the East India Company to be Professor of Chemistry at the Calcutta Medical College, a post which carried with it the appointment of Chemical Examiner to the Indian Government. He interpreted his duties in each capacity in the most liberal way, devoting 17 of the best years of his life to carrying on numberless sanitary, chemical, and pathological investigations. He was early to point out the danger to a community of using drinking-water that was exposed to the infection of cholera and was one of the initiators of the present scheme by which Calcutta is supplied with pure water. Upon his return to England in 1870 he left the service, but he was appointed Examiner of Medical Stores at the India Office—a post which he was about to resign when he died at the age of 67 years.

Dr. Macnamara embodied his great knowledge of India in his work, "Climate and Medical Topography in their Relation to the Disease Distribution of the Himalayan and Sub-Himalayan Districts of British India," while he contributed many valuable monographs on pathological and chemical subjects and on the disease of warm climates to medical literature.

The following appreciation of Dr. Macnamara is from the pen of his old friend and colleague, Sir Joseph Fayrer:—

"In THE LANCET of March 11th I read with great regret a short paragraph announcing the death of Dr. F. N. Macnamara of the Bengal Medical Service. I little thought when quite recently I st[illegible] mutual friend and coll we should so soon have to deplore the loss of this eminent medical officer, one whose whole life claimed the admiration of his numerous friends and brother officers and who through a long and distinguished career had rendered services of the greatest importance to the country and people in and among whom his useful life had for so many years been spent. The value of these services, though as unostentatiously as earnestly rendered, was thoroughly appreciated though they never that I am aware of received the public recognition they merited, yet they will long be gratefully remembered by the students and Dr. Macnamara's colleagues in the Medical College of Calcutta of which he was so brilliant an ornament, as by all to whom his noble personal character and courteous bearing endeared him. These services, of the greatest scientific importance, were not limited to India, for on his retirement some years ago he was appointed a member of a committee to inquire into and regulate the supply of drugs and medical stores to India and as a result of that inquiry he was appointed by the Secretary of State to supervise the administration of a new department which has worked most satisfactorily and beneficially both to the Government and India and well merits recognition of its importance and value. As an old friend and colleague as well as an admirer of his valuable services I desire to pay this brief tribute to his memory."

JAMES WILLIAMSON, M.D. ST. AND., L.R.C.S. EDIN., L.S.A.,

FORMERLY OF SOUTH SHIELDS.

THE death is announced of Mr. James Williamson, M.D. St. And., L.R.C.S. Edin., L.S.A., at the ripe age of 84 years. Dr. Williamson was the son of a Baptist minister of North Shields, but he was born at Littleborough, near Rochdale. He became the pupil of Messrs. Ingham and Greenhow of North Shields, of whom he always spoke in terms of great respect. He studied in Edinburgh. While yet a medical student and in the interval of sessions he, in accordance with a not uncommon custom of those days, sought employment as surgeon to a well-known Greenland whaler, *The Lady Jane*, which sailed in 1835 from the Tyne. The good ship was unfortunately detained in the ice in Davis Straits from Oct. 5th of that year to Feb. 19th, 1836. On the last-named day a gale of wind broke up the ice and blew *The Lady Jane* into the open sea. In those days no provision for such detention in ice-bound waters was made and the results to the crew were disastrous. They had to live for months on a biscuit a day and 27 of the crew died from scurvy. Only 16 men were left to work the ship to the Orkney Islands where they were all placed in the hospital and sent home to North Shields. This experience made an indelible impression on Dr. Williamson who was the last survivor to tell the story, which he did on occasions, haltingly, but with weird effect. After qualifying in Edinburgh he became resident surgeon to the Dispensary of South Shields. Thereafter he was appointed surgeon to the Jarrow Chemical Company—an office which, with a considerable private practice, occupied all his time. In South Shields he was universally respected alike by the public and the profession. About 22 years ago his energy and health failed somewhat and he retired from practice, settling down in Petherton-road, Highbury, London, N., where he died. In 1897 he celebrated his golden wedding. Mrs. Williamson, three daughters, and two sons, one of them being Dr. James Mann Williamson of Ventnor, survive to feel a loss which, by care and affection, they have done much to postpone. Dr. Glover of Highbury writes to us as follows:—

"I should like with your permission to say a few words about my late and most esteemed master, Dr. Williamson. He was a most honourable example of the general practitioner of his day. He never ceased to take an interest in the profession and in the great revolutions of practice which his long age enabled him to witness. With traces of the old sailor in him dating from his Arctic adventure he was in all respects a gentleman. His tastes were classical. His practice was arduous. His prescriptions were practical. His principles were deep and religious. He was born on Dec. 9th—Milton's birthday. Though he did not much affect poetry he was Miltonic in his Puritanism, his religion being simple in its strong faith and in all the virtues which grow out of such faith. Though a staunch Nonconformist he was conservative in his religious creed and in his resistance to such views as Darwin's, but on all ordinary subjects he was liberal almost to the degree of being radical. As a friend he was invaluable and unchanging and taken for all in all, I do not expect to meet a man more kind, more upright, or more devout."

JOHN ROSE, M.D. ABERD., L.R.C.S. EDIN.

ON March 7th, at the age of 76 years, Dr. John Rose of Dale Bank, Chesterfield, passed away peacefully and painlessly in his sleep. He had enjoyed good health most of his life and was of a most happy and contented disposition, and he took delight in helping those to whom he was able to be of service either in a professional or in any other capacity. A few years ago it was found that the valves of his heart were not quite sound and he was enjoined to take life easily, which his circumstances fortunately enabled him to do. Dr. Rose never married. His domestic affairs were managed by his niece who tended him most devotedly and his declining years were passed in absolute comfort, the state of his health allowing him to go about up to the end. Dr. Rose was a good Churchman, a staunch teetotaler, a true friend, and an honest, upright man. He was born at Perth House, Banff, on Sept. 20th, 1822. His university education was received at Aberdeen where he graduated as M.A. at King's College in 1840 and at Marischal College as M.B. in 1846 and M.D. in 1847. He also took the diploma of L.R.C.S. Edin. in 1846. He then passed his examination for the Royal Navy and was stationed for some time at Haslar Hospital. He was surgeon on H.M.S. *Frolic* in the Mediterranean and staff surgeon on H.M.S. *Flying Fish* and H.M.S. *Nimrod* during the China war in 1857-58, being awarded a medal with two clasps for services rendered at that time. He was staff surgeon to H.M.S. *Eagle* in 1859. He was author of "Letters from the Mediterranean," "Notes on China," and numerous articles and reports of medical and surgical cases in the medical journals. On retiring from the naval service he became resident surgeon to the Kidderminster Infirmary, where he remained nine years, leaving that for a similar appointment at the Chesterfield and North Derbyshire Hospital—a post which he held for 23 years. Upon relinquishing the active duties of the latter office he was made honorary consulting surgeon to the hospital and he settled down at Dale Bank, where he died. Botany was a very favourite study with him all his life and he derived much pleasure from it during his later years. He was interred on March 11th in the churchyard of the picturesque village of Ashover.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Angelo Knorr, one of the *privat-docenten* teaching bacteriology in Munich, while engaged in the investigation of glanders had the misfortune to contract the disease, which proved fatal. He was formerly assistant in the Berlin Institute for Infectious Diseases.—Dr. H. M. Tarnovski, Director of the St. Petersburg Maternity Hospital.—Dr. Manoel Joaquim Saraiva, Professor of Hygiene in the University of Bahia.—Dr. James Henry Etheridge, Professor of Midwifery in the Rush Medical College, Chicago.

LITERARY INTELLIGENCE.—The Cambridge University Press is about to publish a new work on "Fermentation" from the pen of Professor Reynolds Green. The subject will be treated more broadly than has been usual, a good deal of space being devoted to a discussion of the relation of the soluble ferments or enzymes to the general problems of fermentation. The author inquires also into their own special peculiarities and the resemblances and differences between them and the so-called organised ferments or microbes. The book will form the next volume of the Biological Series which is now appearing under the editorship of Mr. A. E. Shipley, of Christ's College.—Messrs. Baillière, Tindall, and Cox have in the press a new edition (the third) of Sir William Broadbent's "Diseases of the Heart," with additional chapters and illustrative cases; a new work by Sir Richard Thorne Thorne on "The Administrative Control of Tuberculosis"; a new work by Mr. Berkeley Moynihan, F.R.C.S. Eng., Arris and Gale Lecturer at the Royal College of Surgeons of England, on "The Anatomy and Surgery of the Peritoneal Cavity," and several new editions of well-known works.

Medical News.

Tasini as *privat docent* of Surgical Pathology and Operative Medicine; and Dr. Arnaldo Fumagalli as *privat-docent* of Ophthalmology.—*Prague (German University):* The vacant chair of Midwifery and Gynæcology has been offered to Dr. Leopold of Dresden who was formerly professor in Leipsic but he has declined it.—*Strasburg:* Dr. Oscar Roemer has been recognised as *privat-docent* of Odontology, and Dr. Heinrich Ehret as *privat-docent* of Internal Medicine.

MEDICAL LONGEVITY.—Surgeon-Major John Bowron who died at Hove on March 5th entered the East India Company's service as a medical pupil in the year 1813 and was promoted to be an assistant-surgeon on the Bengal establishment in 1825. He retired from the service in 1851 with the rank of surgeon-major.

PRUDENTIAL ASSURANCE COMPANY, LIMITED.—The recently published accounts and balance-sheets show that the business of this prosperous company increased considerably during 1898. In the ordinary branch the number of policies issued during the year was 64,709, assuring the sum of £6,420,580 and producing a new annual premium income of £353,113. The premiums received during the year were £2,957,501, being an increase of £193,237 over the year 1897. The claims of the year amounted to £975,012. The number of deaths was 5191 and 2535 endowment assurances matured. The number of policies in force at the end of the year was 534,138. In the industrial branch the premiums received during the year were £4,960,756, being an increase of £167,165 The claims of the year amounted to £1,891,039. The number of deaths was 193,308 and 2181 endowment assurances matured. The total number of policies in force at the end of the year was 12,949,679; their average duration exceeds eight and a half years. The assets of the company in both branches are £33,599,708, being an increase of £3,161,371 over those of 1897. Provision has now been made for all policy-holders in the industrial branch who have been assured for 25 years to be free from the payment of further premiums as they attain the age of 75 years.

OVERCROWDING AT STOCKPORT WORKHOUSE.—Mr. Dansey, the Poor-law inspector for the district, addressed the guardians at the last meeting of the Stockport Board on a proposal for relieving the overcrowding of the workhouse at Shaw Heath. This was the erection of a three-storey brick building to accommodate 100 sick inmates at a cost of £1800. He did not know whether it was seriously meant or whether it was a very laboured joke. His experience was that the accommodation for sick and infirm persons cost at the lowest £80 a bed instead of £18, but irrespectively of the cost the Local Government Board would not sanction the erection of any more permanent buildings on the site of the present workhouse. He said: "The accommodation for the sick at the Stockport Workhouse was a disgrace to any public institution," which scathing remark was endorsed by the chairman and another of the guardians Mr. Dansey said they had no right to mix different classes of sickness as they did and nearly every ward had too many beds Notwithstanding these strong remarks one of the guardians tried to support the proposition to build a hospital of 100 beds for £1800 by saying "that three competent architects and a number of builders" declared it could be done and he was backed by others. Dr. E Rayner said that "some parts of the workhouse were more suitable for animals in the zoological gardens than for the accommodation of the people now occupying them." From this it may be inferred that they are not fit for the animals in the zoological gardens, as the managers of such places have more liberal views and study the requirements of the creatures under their care with more intelligence and greater humanity than the Stockport Board of Guardians is pleased to exhibit.

HOSPITAL SUNDAY IN BRISTOL.—Jan. 29th was observed in Bristol as Hospital Sunday when the sum of £1492 was raised for the various medical charities of that city. This is an increase of £374 as compared with 1898.

UNIVERSITY OF CAMBRIDGE.—The following medical degrees were conferred on March 11th:—Doctor of Medicine: R. D. R. C. Atkins, of Clare College; and H. C. Pattin, of Jesus College. Bachelor of Medicine and Bachelor of Surgery: F. J. Lidderdale, of Trinity College; H. M. Hart-Smith, of Caius College; and A. C. Jordan, of Sidney Sussex College. Professor Sims Woodhead received the degree of Master of Arts *honoris causa* on March 16th.

THE LATE MR. R. W. PENDLETON.—Mr. Richard Warren Pendleton, M.R.C.P. Irel., son of the late Captain Henry Pendleton, Co. Meath, Ireland, died on March 4th at his residence, Sillwood Lodge, Brighton. He commenced practice in Liverpool, but ill-health compelled him to go to Port Augusta, in South Australia, where he remained for eight years Whilst there he met with a carriage accident which seriously affected his spine and permanently impaired his health. In 1887 he returned to England and after undergoing treatment he started a medical home at Brighton. His death was due to double pneumonia which lasted only five days. He was 58 years of age and by his wonderful patience in suffering he endeared himself to all who knew him.

DIPHTHERIA IN LONDON.—The amount of notified diphtheria in London during the second period of four weeks of the current year was almost identical with that of the first period ended on Jan. 28th. In the January period there were 959 notified cases and 957 in the February period, the respective weekly averages being 240 and 239. In January there was but one district uninvaded, as also in February. In January four sanitary districts had each upwards of 50 notified cases, with an aggregate of 289; in February there were five such districts with an aggregate of 365 notified cases, whilst other five districts had only nine cases in all. The 125 registered deaths of the January period, averaging 31 per week, gave place to 150, or 37 per week. The 150 were made up of 32 (being 14 below the corrected decennial average of the corresponding week of the period 1888-97), 49 (being 8 in excess of the average), 40 (identical with the average), and 29 (being 13 below the average). The case mortality of 13 0 per cent. of the January period was succeeded by one of 15 6 per cent. in the February period. In the Outer Circle the data were of serious import. The 57 deaths in the earlier period gave place to 70, or 17 per week. In other words, the suburban ring yielded nearly half as many deaths as the whole of the county of London with its much greater population. But if this be said of the fringe of London as a whole much more must needs be said of the single area of the West Ham registration district. Herein were 20 deaths in the January period, but as many as 38 in the February period, a little over a fourth of the diphtheria death-rate for the whole of London and 17 per cent of the whole of the diphtheria deaths in the four weeks in Greater London. The matter calls for serious notice.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1898, which was completed with the issue of Dec. 31st, and the Title-page to the Volume, were given in THE LANCET of Jan. 7th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1898 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 6*d.*

To be obtained on application to the Manager, accompanied by remittance.

MEDICAL INFORMATION IN LAY PAPERS.

THE following answer to a correspondent appeared in the *Gentlewoman* of March 11th, 1899, and has been forwarded to us by a correspondent who asks us what we think of it:—

> "As Paying Guest in a Lady's House in Hereford for Medical Treatment.—You will certainly recover in a better climate. I know from experience how trying the Indian heat is, for I have been in exactly the same predicament as yourself. You cannot do better than pick up your strength in the warm, bracing climate of the Riviera on your way home. But I must warn you that the French Riviera in spring is not cheap; and in the very moderate priced houses you will, of course, not find a large amount of comfort. I recommend you to try Hyères, where, at the Hôtel de France, you will be exceedingly comfortable for 7 francs a day. Now for your questions. 1. In Hereford you cannot do better than put yourself under Dr. Turner who is the principal medical man in the town. His address is St. Owen's-street. All doctors of modern ideas are now favourable to the use of chloroform in cases like yours, provided the patient (and you will be after a little Europe) is physically fit. 2. I cannot tell you of any lady taking paying guests for treatment in Hereford, but I should suggest your writing to Dr. Turner to inquire. It is against my rule to recommend lodgings, but as you are so far away and your case is one that will not wait, you can rely upon being comfortable at the following address: Miss Elliott, 21, Broad-street, Hereford. (K. F., Mhow.)"

We think as follows:—

(1) That the writer assumes a grave responsibility in promising certain recovery to a patient upon the strength of the patient's own description of her symptoms; (2) that this fact alone goes far to prove that the person giving medical advice *is not* a medical practitioner; (3) that Mr. Thomas Turner, F.R.C.S. Eng. L.S.A., will resent the publicity that has been thrust upon him in a lay paper all the more that he has been exalted at the expense of his 19 other medical colleagues in that city and that he will not know himself in the character of a man who recommends lodgings; and (4) that the writer of the reply should for the future make the same rule about medical men as for lodgings and abstain from recommending them.

The whole question of medical advice in lay papers is one which requires the serious consideration of medical men and of the public. When we in THE LANCET raise up our voice against the system of treating disease by correspondence we lay ourselves open to a double suspicion of being narrow and jealous in our views. Firstly, it is alleged that in an eagerness to speak on behalf of the medical profession we lose sight of the possibility that it might be for the good of the public to be able to obtain this sort of medical advice. Secondly, it is suggested that we desire to keep for the medical press a monopoly in medical information. To deal with the latter and the totally unimportant point first we have only to say that we do not cater for the public, that we do not give medical advice, and that we do not recommend medical practitioners. The larger matter is worth a little more consideration and we would impress upon our readers the desirability of pointing out what follows to their patients whenever opportunity arises. Why should the public pay a medical man to diagnose and treat its diseases when the obliging editor of a lay paper will give his assistance for nothing? This is the practical way in which the public may speak. The answer is that the assistance is worth nothing. The persons who are responsible for the replies to the medical queries in lay papers are generally not medical men and never medical men of any standing in their profession. This is implied by the fact that no serious medical man would attempt to diagnose and treat patients upon their descriptions of their symptoms and proved by the nature of the replies wherein serious mistakes often abound. In our opinion, medical men should use their undoubted influence with the public to urge the unseemly and dangerous nature of the so-called "medical" columns in the lay press.

The example we have quoted at the head of this note is a favourable one in that it contains no silly recommendation to abstain from all physic, no poisonous prescription, and no diagnostic guesses. We may be certain what Mr. Turner's opinion of the reply will be; and we hope that he will let the editor of the *Gentlewoman* share it with him, for he has our sympathies in the disagreable position in which he has been placed through no fault whatever of his own. For we know that he has not been privy to the advertisement of his merits.

DR. LAPPONI ON THE POPE'S ILLNESS.

IN a letter addressed *ad populum* rather than *ad clerum* Dr. Lapponi explains to the Roman Catholic world why the hæmatic cyst recently removed from the left lumbar region of his august patient was not operated upon at an earlier date. He says: "A cyst in irritation ought to be removed without delay, even in the case of an old man. A cyst not in irritation may be operated upon in a young man; not always in an old man. Violent pain may be the cause of death by syncope. In a young man chloroform may be employed; not always in an old man. In the Pope's case the operation was not attempted some years back because the difference of age remaining constant the other conditions of health offered no advantage over the present state. He who is old at 90 years is not young at 85. The operation was not performed before because the pain felt and the risk incurred under the knife in a nonagenarian subject would have had equally, but with anticipation, to be overcome in one five years younger. ...... Such a cyst in a state of tranquility is an inconvenience, not a disease. If a disease ought always to be combated an inconvenience ought occasionally to be tolerated for fear of making matters worse. ...... These considerations, as they influenced Professor Madruzza 25 years ago and Professor Ceccarelli 10 years ago and more recently other able surgeons, so they influenced me in withholding active intervention. So long as it was possible I preferred a 'masterly inactivity,' practising precautions of a subsidiary kind. I wished to do to another what in similar circumstances I should have wished done to myself, employing a continuous and rigorous vigilance, and decided not to incur the risks inseparable from operation, unless circumstances left no other course possible. Certainly the surgical treatment of a voluminous hæmatic cyst not in inflammation is more propitious than similar interference in a parallel cyst when inflammation is present. ...... Be all this as it may, the success of the operation seems amply to justify the prudent, vigilant, expectant course, which, up to a few days ago was imposed on me, and which, to every experienced and loyal surgeon, cannot but appear, on the grounds of humanity as well as of science, to have been the most correct one."

MEDICAL AID SOCIETIES.

To the Editors of THE LANCET.

SIRS,—Although it is difficult to ascertain the number of trading companies which exploit the profession with reference to the provision of medical aid, yet I am assured from several correspondents that a very large number of men do lend themselves and their names towards increasing the business of these purely money-earning societies. We as a profession can hardly interfere with the work of insurance companies, although we may have our doubts as to the wisdom of promoting the insurance of infants' and children's lives; but when these so-called insurance companies employ men to canvass or tout for clients for medical purposes, then I think it is full time that some strong protest should be made. That the medical officers are perfectly aware of what the agents of these companies do can hardly be denied. It is much to be deplored that medical men have copied the objectionable tactics of these associations and have themselves employed canvassers or "touts" for private family clubs. Surely, Sirs, the time has come when the profession as a body should speak out, and speak out boldly, on the undignified and lowering tactics pursued.

I am, Sirs, yours faithfully,

March 6th, 1899. A GENERAL PRACTITIONER.

EXPERIMENTAL LIGATURE OF THE MESENTERIC VESSELS.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if either you or one of your correspondents could give me some information on the following matter. I am under the impression that during the last year or so some experimental work has been done in animals on ligaturing certain branches of the mesenteric artery and vein to see the effect that the vascular occlusion may have on the part of the bowel supplied by that vessel with regard to the production of intestinal infarction or gangrene, the ligatures being placed at varying distances from the bowel in different experiments. I am unable to refer to this work anywhere, and if it has actually been done, I should be much obliged if one o your readers could give me the reference.

I am, Sirs, your faithfully,

March 13th, 1899. INQUIRO.

INTRACTABLE ECZEMA.

To the Editors of THE LANCET.

SIRS,—I should be very much obliged if any of your readers could give me suggestions for the treatment of a case of intractable eczema, probably gouty in origin. There is a small patch on the corona glandis, dry and scaly at times, of two years' duration, which has resisted all remedies. The patient is an adult who drinks moderately and takes plenty of exercise; there is no history of syphilis.

I am, Sirs, yours faithfully,

March 13th, 1899. W. K.

"THE THERAPEUTICS OF COMFREY."

To the Editors of THE LANCET.

SIRS,—Permit us to offer a word in reply to the inquiries of "W. S." in THE LANCET of March 11th. Comfrey may be used externally as a poultice in two ways—viz., (1) the whole plant, (2) the root. (1) the whole plant may be boiled until soft, then beaten up and applied hot; (2) the root is used far oftener than the whole plant, and the apparent good experienced by this form of treatment of tumours has been nearly always ascribed to the root. It is boiled in water till soft; then beaten into a pulpy mucilage, and spread upon leather, or linen cloth. If too liquid it may be brought to a proper consistence by the addition of a little of the dry powdered root. About two years ago the then President of the Irish College of Surgeons reported the gradual disappearance of a growth (malignant, sarcomatous, twice recurrent, and of a bad type) after steadily applying poultices of comfrey root to the tumour. "I know nothing," said

Professor Sir William Thomson, "of the effects of comfrey root, but the fact that this growth has simply disappeared is one of the greatest surprises and puzzles I have met with." Sir William Thomson resides in Dublin and would no doubt be pleased to answer any questions respecting it which "W. S." might prefer. The medicinal virtues are believed to lie in the mucilage of comfrey, which contains tannin, asparagin, sugar and starch granules, &c.

Chelidonium majus.—"W. S." also asks about the internal treatment of similar cases by chelidonium majus. Denisenko has re-introduced it as a remedy for cancer. In internal cancer he administers an extract of the drug; in external cancer he not only does that but also resorts to an injection locally in addition—an injection composed of the extract two parts, water one part, and glycerine one part, of which he injects one cubic centimetre as a dose.

We are, Sirs, yours faithfully,

March 14th, 1899. PARKE, DAVIS AND CO.

CAMPHOR IN THE TREATMENT OF PHTHISIS.

WE have received from Dr. Bruno Alexander of Nervi and Reichenhall an 11 page pamphlet reprinted from No. 48 of the *Berliner Klinische Wochenschrift*, 1898, strongly recommending the subcutaneous injection of camphorated oil in pulmonary phthisis. If the patients' temperatures are raised, he gives a subcutaneous injection of 0·1 or 0·2 cubic centimetre (one and three-quarter minims or three and a half minims) of camphorated oil once a day for a long time—for from four to six weeks without interruption; he then allows an interval of from one to four weeks, after which the injections are resumed. The oil used is the oleum camphoratum of the German Pharmacopœia, containing 10 per cent. of camphor, so that the above quantities correspond to subcutaneous injections of one-sixth of a grain or one third of a grain of solid camphor. If the patients' temperatures are not raised he gives larger doses for a shorter time—namely, from 0·3 to 0·5 cubic centimetre of oil (i.e., from half a grain to three-quarters of a grain of camphor) for from eight to 14 days, followed by an interval of eight days, after which the injections commence once more. Another method of treating a pyrexial patient is by daily injections of one cubic centimetre of oil (i.e., one and a half grains of camphor) for four days, followed by an interval of eight days.

WANTED A SUGGESTION FOR TREATMENT.

To the Editors of THE LANCET.

SIRS,—I should be exceedingly obliged if some of your readers would help me with the prognosis and treatment of the following case. In November of last year a friend of mine noticed her right hand to swell one day after it was kept in a strained dependent position for some little time. It became stiff and painful. In the shoulder pains were also felt at intervals. It was diagnosed as a case of subacute rheumatism and the routine treatment for same was used, but after a month the pain and stiffness were there as at the commencement. Both were aggravated by any effort at piano playing and then she felt as if the sinews were too short; indeed, for some time after she could not straighten the fingers. It should have been mentioned that previously to the onset of the symptoms mentioned the lady was [illegible] incessant pianoforte player. As she did not derive any [illegible]om the rheumatic treatment she consulted another medical [illegible]e at once said it was a case of "pianist's cramp" and advised massage, electricity, and general tonics. The two former have been used almost daily for six weeks and she thought she was getting quite well again, but yet she feels the fingers quite stiff and wooden if a few notes only are played. Can anyone suggest any other treatment than that already mentioned together with total abstinence from the use of the pianoforte and how long does such a disease take to get well?

I am, Sirs, yours faithfully,

March 14th, 1899. MEDICUS.

THE SCOPE OF THE PENAL WORK OF THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—The General Medical Council has drafted a short Bill for the consideration of the Privy Council dealing with registered medical practitioners who "after due inquiry" have been judged by the Council "guilty of infamous conduct in a professional respect." What we, as members of the profession, complain of is that the Council troubles itself very little about medical men who are guilty of infamous conduct. Judging from the cases that from time to time are dealt with by the Council "covering" unqualified assistants and "advertising" are the chief sins committed and condemned. What has the Council done to medical men who sell practices and partnerships under false pretences? What punishment has been meted out to registered practitioners who have evaded the terms of a deed or wilfully disregarded them to suit their own purposes? There are dozens of cases annually of this kind of "infamous conduct in a professional respect"—i.e., in dealings between medical men themselves—which the Medical Council should carefully look into and severely punish. Occupying as it does the position of a medical court from which there is no appeal, it seems to fail in its duties towards the profession as a court of appeal. I have been informed by one who is well up in the details that the Council will not bring a practitioner to book for breaking or evading the terms of a deed of partnership or of dissolution of partnership, and that even if the plaintiff obtains damages in a court of law the Council will not take any notice of the matter. Surely, if medical men are proved guilty of behaving in an infamous manner towards one another (e.g., by evading the terms of a deed, by "over reaching and under-selling") the Council is the proper authority to take up such cases and to remove from the Register the name of any such practitioners. When this is done there will be less "farming" and selling of practices under false pretences, and less "poaching" in a district after selling the rights of practising in it. If the present members (or some of them) consider this to be outside the scope of the Council it is time for them to retire and for others with more determined and higher views to take their places.

I am, Sirs, yours faithfully,

"MAKE THE PUNISHMENT FIT THE CRIME."

TREATMENT OF HICCOUGH.

IN the *Maryland Medical Journal* of Feb. 25th, Dr. Louis Kolipinski of Washington records a case in which persistent hiccough was immediately checked by depressing the tongue. The patient, a man, 69 years of age, began to hiccough on Dec. 14th, 1893. Next day he was not able to take his meals or to work at his trade. He slept but little, the hiccough being so violent that his bed shook, and he passed the night mostly sitting up. During the next three days his state continued the same; on Dec. 17th and 18th his throat felt swollen and full and he was in dread of death by suffocation. On Dec. 18th, while Dr. Kolipinski, in order to examine the patient's throat, was pressing his tongue downwards and backwards with the handle of a large spoon using continuous steady force, the hiccough suddenly ceased. An hour afterwards it returned, but the patient placing himself in front of a mirror stopped it by using the spoon in a similar way. Two days later it reappeared but was promptly arrested by the patient as before.

THE MEDICAL WRITER IN THE LAY PRESS.

To the Editors of THE LANCET.

SIRS,—I have been asked by a firm of publishers to write a small book for domestic use on *Diseases and Management of Children* and it is proposed by them that a column be published each week in several of the provincial lay journals. Can you advise me if this course would be thought wrong or in any way unprofessional? I told them I could not consent to anything being done in that way without your advice.

I am, Sirs, yours faithfully,

March 10th, 1899. A. J. G.

*** The publication of the work as a serial in provincial lay journals would be most inadvisable. The procedure would certainly give great offence to the medical profession and such feeling would not be unreasonable.—ED. L.

◆

C. K.—Horse ambulances are in existence. We believe they answered their purpose exceedingly well and we have more than once expressed our surprise that there are not more of them in use. Motor traffic is still infantine.

M.B. wishes to ascertain if puerperal eclampsia is as frequent amongst the purely vegetarian races as in the British Isles and appeals to our readers for assistance.

E. H. B.—It is unfortunately not possible to recommend any place, for locality is a mere matter of experiment. Patients are generally free at sea.

Mrs. C. K. Hunter desires us to publish her full address. It is 139, Warwick street, London, S.W.

Anæsthetist has not enclosed his name and address.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received: *Eastern Daily Press, Sun, Manchester Courier, Liverpool Mercury, Hereford Mercury, Western Daily Press, Leicester Daily Post, Birmingham Argus, Times of India, Pioneer Mail, Scotsman, Builder, Citizen, Architect, Yorkshire Post, Brighton Gazette, North British Daily Mail, Leeds Mercury, Irish Figaro, First Aid, Liverpool Daily Post, Flint County Herald, Bristol Mercury, Sheffield Daily Telegraph, Cheltenham Examiner, Sanitary Record, Folkestone Express, East Anglian Times, New Ross Reporter, Daily Chronicle, Science Siftings, Watford Leader, Truth, Chard News, Eastbourne Gazette, Coventry Daily Telegraph, Kent Herald, Chester Courant, Taunton Echo, Essex Chronicle, Dundee Advertiser, The Stockkeeper and Fanciers' Chronicle, Crystal Palace Times, Doncaster Chronicle, Mining Journal, Hertfordshire Mercury, Reading Mercury, Local Government Chronicle, City Press, Pontefract Telegraph, Newry Standard, Dentist, Surrey Advertiser, Burnley Gazette, Eastbourne Chronicle, Local Government Journal, Harrogate Advertiser, Chiswick Times, Burton Evening Gazette, Yorkshire Weekly Post, Durham Chronicle, Slough Observer, Citizen (Gloucester), Derbyshire Times, South Wales Echo, Worcester Daily Times, Liverpool Courier, Islington Gazette, Madras Standard, &c.*

The Lumleian Lectures

ON

BRONCHITIS, PULMONARY EMPHYSEMA, AND ASTHMA.

Delivered before the Royal College of Physicians of London on March 16th, 21st, and 23rd, 1899.

BY SAMUEL GEE, M.D. LOND.,
FELLOW OF THE COLLEGE AND PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

LECTURE II.[1]

Delivered on March 21st, 1899.

ON THE NATURE OF PULMONARY EMPHYSEMA.

MR. PRESIDENT AND GENTLEMEN,—In 1764 Dr. William Watson (who afterwards became a Fellow of our College and a knight) read before the Royal Society "An account of what appeared on opening the body of an asthmatic person." He described what he called an "emphysematous state of the lungs," a condition which he deemed to be due to an "extravasation" of air into the lungs from the "bronchia and vesicular substance," and what was no doubt vesicular emphysema of the lungs in the sense which we give to that phrase. Pulmonary emphysema has been known in one of its results—namely, the barrel-shaped chest—from the time of the ancient Greeks. The lesion of the lungs themselves was first noted by Valsalva and Ruysch in the earlier part of the last century. However, Laennec was not far from the truth when in the first edition of his great work published in 1819 he said that "emphysema of the lungs, such as he had described it, seemed to him to be a disease hitherto unknown."

It is universally agreed that the note of pulmonary emphysema is to be found in enlarged capacity of the acini and lobules of the lungs beyond what can be produced in health by the deepest inspiration. This change in the structure of the lung, the anatomical characteristic of emphysema, is pretty thoroughly known; but when we come to inquire into the process which leads to emphysema the case is very different. For we cannot know the process in the same way as we know the result; we cannot watch the lungs becoming emphysematous, we can only argue about the process. Deprived of the intuition of sense, the light of nature, we must follow the light of reason and beware lest it prove to be *ignis fatuus*. And unfortunately we can get no help from experimental pathology; we cannot set up progressive emphysema in the lower animals and mark its stages in the same manner as we can set up inflammation. Hence the many theories of emphysema and long discussions which, however, do not dishearten me from attempting the difficult topic once more; my only fear is lest I should weary you.

ACUTE EMPHYSEMA.

The emphysematous process, like all nature's processes, may be assumed to be complex, and we shall do well to begin by endeavouring to resolve it into its simplest elements. Nature itself helps us much by offering to our consideration a form of emphysema which certainly is simpler than ordinary emphysema and which seems to consist in a mere over-distension of the lung. I allude to the acute emphysema first adequately described by Fauvel in his essay upon capillary bronchitis. You know the condition—both lungs distended with air, *as if insufflated* by the fullest possible inspiration, but some parts of the lung distended more than this, emphysematous, in short, and especially so in the upper lobes and their anterior portions. You know that this acute emphysema is especially met with in young children who have died *from suffocating* capillary bronchitis or *from* diphtheritic croup. Many of these children will have enjoyed the most perfect health until they are attacked by the bronchitis or croup, so that there is no question in them of any preceding disease of the lungs. The suffocating bronchitis will often prove fatal within a week *from* its beginning; croup will kill in a still shorter time; and there is a disease, very much less common—namely, hæmorrhage into the air passages—which may suffocate in a few minutes, acute emphysema being found post mortem in all cases.

Let us turn our attention to croup in the first place, inasmuch as it is often entirely free from one condition which might complicate the question—namely, collapse of the lung. For although fatal croup is usually associated with abundant puriform secretion into the small air tubes of the lungs, yet in spite of this form of bronchitis there is sometimes no collapse at all even when the lungs have become highly emphysematous, *so* that collapse, when *present*, can be no more than somewhat contributory to the emphysema. In other words, the emphysema is but slightly, if at all, compensatory to any collapse. John Cheyne in his book on the pathology of the laryngeal and bronchial mucous membrane published in 1809 *frequently* alludes to the emphysema and puriform catarrh of croup. For example, he says: "The lungs were so filled that they did not recede in the least when the thorax was opened; every surface which was cut poured out this puriform fluid from several points."

Setting collapse aside, the conceivable causes of acute emphysema are two—namely, dyspnœa and cough; that is to say, the movements of dyspnœa and of cough, not overlooking the fact that they usually concur. Here also the question is simpler in the case of croup. In capillary *bronchitis both dyspnœa and cough are great and therefore* the question of the associated emphysema is complicated. But in croup the dyspnœa is extreme, while the cough is insignificant or even absent, so that it may be left out of consideration, and all this in cases affording a high degree *of insufflation and emphysema of the lungs.*

Our analysis thus leads us to infer that dyspnœa is the cause of acute emphysema. Now, the movements of dyspnœa are forced movements, inspiratory or expiratory, or both. But before proceeding further with this part of our subject let us cast a short glance upon the movements of breathing in general.

From the earliest times the diaphragm has been regarded as the essential agent of respiration. We may say of respiration, and not of inspiration only, because expiration is little more than a result of inspiration. Galen was the first to show that most of the intercostal muscles were ordinary muscles of inspiration. Guided by the researches of Duchenne we may disregard the exceptions which Galen made and we may say that all the intercostals act simultaneously and *are employed in ordinary quiet inspiration.* They not only raise the ribs but keep the intercostal spaces tight during the descent of the diaphragm. When the intercostal muscles are paralysed but the diaphragm is not, the upper two-thirds of the chest are motionless.

The chest may be roughly compared to a bow, inspiration to a bow when pulled upon by an archer, and expiration is little more than the elastic recoil of the bow when the archer lets go the string. But the inspiratory muscles do not altogether let go when expiration begins; they continue to act *as moderators of the expiratory movements and hence* expiration is more gradual than it would be were it a mere elastic recoil. In short, the muscular contractions of expiration are persisting contractions of inspiratory muscles unless the expiration be forced and then extraordinary muscles of *expiration come into play.*

Physiologists seem to be agreed that although the outward pressure of the air at the mouth during expiration is greater than the pressure inwards during inspiration, yet the forces concerned in inspiration are decidedly much greater than those of expiration. These propositions at first sight seem to be discrepant, but we are not called upon here to explain the apparent discrepancy—we will only remark that they indicate a provision in the human economy for repressing the greater powers of inspiration. Let us especially note that the elastic retraction of healthy lung is not satisfied by the deepest expiration and that the lungs are provided with a considerable reserve of elasticity, so necessary is it to maintain sufficient deflation of the lungs, or in other words to keep them sufficiently empty of air. For if there be insufficient efflation there must be insufficient inflation.

In the forced breathing of healthy persons there is the same disproportion between the powers of the antagonist movements. But physiological experiments relate to a few forced respirations studied in a healthy subject. The forced breathing of disease introduces a new set of conditions and requires that we proceed to an analysis. The
muscles of inspiration are
the scaleni, and the

No. 3943.

All physicians admit a close connexion of some kind between bronchitis and emphysema—a connexion in many cases so obvious as to be past all doubt, but in other cases not so. Laennec went so far as to say that emphysema is almost always the result of intense and extensive *catarrhe sec.* All writers on emphysema mention this opinion of Laennec; few, if any, adopt it or even discuss it, but no opinion of that remarkable man can be passed over lightly. What does he mean by dry catarrh? He himself admits that the phrase is a contradiction in terms; to find appropriate names for diseases was not a strong point of his; witness his perversion of the meaning of the word "apoplexy" in his phrase, "pulmonary apoplexy." But medical writings are full of this fault, and Laennec is no worse than many other physicians. A better name than dry catarrh would be dry bronchitis *(bronchitis sicca)*, for the word "siccus" as applied to pulmonary diseases denotes scantiness or absence of expectoration. Stoll speaks of "pleuritis sicca" and "pleuritis humida"; Hippocrates of "dry orthopnœa," and the phrases "dry cough" and "dry asthma" are colloquial.

In the lungs of persons who died in an early stage of dry catarrh Laennec used to find the mucous membrane of the bronchia swollen and dull-red or violet in colour—conditions most notable in the smaller bronchia, which might be almost completely obstructed by the swelling. The extent of the swelling was not more than a few lines, the mucous membrane in the same tube above and below being natural. This local bronchitis was extensive in proportion to the duration of the disease. When the dry catarrh was universal or even very extensive it always ended by determining emphysema. He often found the partially obstructed tubes to be plugged by pellets of viscid mucus of the size of hemp or millet seeds, and it is these mucous pellets which make up the pearly sputa which such patients, even when they think there is little or nothing the matter with them, expectorate in small quantity every morning.

During life the dry catarrh often continues to a slight degree for many years, Laennec goes on to say, or it may be altogether latent, the patient noticing no more than that his breath is shorter than that of other men, especially upon exertion. This dyspnœa increases gradually and the patient becomes subject to attacks bad enough to deserve the name of asthma. The tendency to dyspnœa is accompanied by cough which at the beginning of the disease is, like the dyspnœa, slight. The cough is attended by expectoration of what Laennec calls pearly sputa, which closely resemble the hailstone sputa (*chalazia*) described by Aretæus and Galen. Such is a brief summary of Laennec's characterisation of his *catarrhe sec.*

Now, if we admit that a man in a state of perfect health ought not to cough or expectorate, and also that expectoration implies catarrh, it follows that at no period of the progress of emphysema is that condition unassociated with catarrh. Again, inasmuch as emphysematous patients always become in the advanced stage of their disease manifestly bronchitic or catarrhal, it is reasonable to believe that in the early stage also their cough and expectoration indicate slight bronchitis or catarrh. Lastly, the symptoms of progressive emphysema (as I have already attempted to depict them) and those of Laennec's dry catarrh seem to relate to the same disease looked at from two different points of view.

We have now reached a position which enables us to resume our discussion of the nature of emphysema. Starting from the note of progressive emphysema—namely, the atrophy of lung tissue—the problem may be resolved into a choice between these alternatives. Is there a primary degeneration of lung tissue, rendering it apt to be permanently distended and also to be destroyed particle by particle? Or is the atrophy due to distension of the lung, and if so, what causes the distension? In briefer language, is the atrophy primary or secondary? The easiest answer is that which assumes the atrophy to be secondary to distension. Laennec asserts that "pulmonary emphysema is almost always developed in consequence of intense and extensive dry catarrh," and we have seen that clinical observation supports this opinion. But in speaking of the priority of catarrh we must understand it only as a priority of order and conception and not as a priority of time. Another argument in favour of Laennec's opinion is this, that inasmuch as acute emphysema is undoubtedly dependent upon bronchial affections it is probable by analogical reasoning that chronic emphysema likewise is so. I will not repeat Laennec's explanation, which you all know, concerning the manner in which he supposes dry catarrh to lead to emphysema, and I will only remark that his hypothesis is not so easily set aside as some people think by pointing out that the air-current at the mouth of a healthy man is more powerful during expiration than during inspiration, for the conditions in pulmonary catarrh are obviously not the same.

Let us fix our attention upon the fact of the barrel-shaped chest in cases of emphysema. It is a chest more capacious than a healthy chest could be rendered by the deepest and most powerful inspiration. The distended chest is a sign of distended lungs, and this fact puts before us a disjunctive hypothesis: either the distended chest distends the lungs, or the distended lungs distend the chest. Now the latter hypothesis affords no explanation at all, because it leaves the distension of the lungs unexplained; and the cause of this pulmonary distension or emphysema is the very thing we are asking for. Wherefore let us consider the former hypothesis—namely, that the distension of the lungs is consequent upon increased capacity of the thorax. In normal inspiration which fact precedes the other—dilatation of the lungs or dilatation of the chest? And by what powers can the chest be over-distended? Obviously by the inspiratory muscles, ordinary and extraordinary, and by no others. And if the chest be over-distended, what must ensue? Over-distension of the lungs, because the potential vacuum caused by extraordinarily deep inspiration is certainly not filled up in any other way.

In health the inspiratory distension of the lungs is exactly countervailed by the expiratory contraction. Why, then, in the barrel-shaped chest is this no longer the case? Obviously because the expiratory powers have been unequal to the task of restoring the chest to its natural shape and size. That is to say, the expiratory powers are no longer equal to the inspiratory. And is not this a sufficient reply to those who, relying upon spirometrical observations made upon healthy people, reject Laennec's explanation of the mechanism of emphysema.

In emphysema, then, there is failure of expiratory power; nay, more, this is the essence of emphysema. Expiration being no longer able to rid the lungs of their exhausted air, ordinary inspiration cannot supply the necessary quantity of fresh air. And there is only one means by which the expiratory failure can be met, and that is by inspiratory movements extraordinary in power and amplitude. These extraordinary inspirations being repeated for weeks, months, and years the chest becomes permanently over-distended and hence the lungs become permanently over-distended and this is emphysema.

We have no clear and certain knowledge respecting the nature of the expiratory failure. We may conceive it to be absolute or relative. Absolute—that is to say, the elastic and muscular movements of expiration are weakened; relative—that is to say, the resistance which expiration has to overcome is increased. 1. The notion of an *absolute* debility of expiratory movement must relate to the elasticity of the lungs only, because there is no reason for supposing the elastic or muscular movements of the chest to be primarily weakened. And thus we are led back to the question of degeneration of lung tissue, either primary or secondary to other disease—an obscure topic which we will again defer for awhile. 2. But the notion of a *relative* debility of expiration is that which lies at the bottom of Laennec's doctrine, the resistance to expiration being increased by the presence of mucous plugs in the air-tubes and by swelling of the mucous membrane. True, reply his critics, but these obstructions are equally great for inspiration as for expiration, and thus we are again met by the question concerning the relative powers of inspiration and expiration—a question which is answered by reiteration of the fact that nature has provided us with very feeble means of reducing by forced expiration the distension of the chest and lungs produced by forced inspiration. The extraordinary muscles of expiration are inadequate, whilst as to the elastic tissues of the lung we may hazard the conjecture that if overstrained they do not easily recover, and it is only inspiration that can overstrain them.

Now, just to consider for a moment the question whether the over-distended chest can possibly be due to over-distended lungs. In other words, can we assume a primary over-distension of the lungs powerful enough to distend the whole thorax and to make it barrel-shaped? If so, what distends the lungs? Forced expiration is sufficient to distend certain portions of lung which are unsupported by bone or muscle, such as are the apices. But more than this is inconceivable; it is inconceivable that expiration, how forcible soever, can produce a shape of chest which is identical with that produced by forcible inspiration. Again, a favourite seat of emphysema is the undermost surface of the lung where it lies upon the diaphragm; how can coughing—an act during which the diaphragm is driven powerfully upwards—over-distend this portion of lung? Surely it is the powerful inspiratory descent of the diaphragm which produces this effect; and let us remember that the forced expiration of persons coughing, of musicians, or of horses tugging up a hill is rendered possible only by a preceding forced inspiration. In short, we cannot understand the occurrence of a primary over-distension of the lungs sufficient to distend the thorax.

Now to discuss and finally to dismiss the question of the degenerative lung changes. In the first place, it is probable that the elasticity of the lungs is injured if the tissues be much or often overstretched, and any such loss of elasticity must tend to increase emphysema by weakening expiration. In the second place, it is very reasonable to believe that the anæmia, which is the visible and undoubted result of over-distension of any portion of the lung, will cause degeneration and atrophy of the tissues thus imperfectly supplied with blood. In the third place, it is possible that there is such a lesion as primary atrophy of lung, analogous to the atrophy and perforations which we often observe in the omentum, falx cerebri, and valves of the heart. In the fourth place, it is not unlikely that the form of pulmonary emphysema in which the total size of the lung is not increased, "atrophous emphysema," is an atrophy of the second or third kind. And, lastly, there are good grounds for believing that even ordinary progressive emphysema with enlarged lungs is from its very beginning an atrophic process, even although to the mind's eye the destruction be secondary to the distension.

To end our inquiry by recapitulating the results at which we have arrived, I submit to your judgment these propositions:—That pulmonary emphysema is chiefly due to forced inspirations, although forced expiration may to some small extent play its part. That the distension of the lung in so far as it is due to inspiration is secondary to distension of the chest. That the forced inspiration is rendered necessary by a feeling of dyspnœa. That the dyspnœa which occurs at the beginning of pulmonary emphysema and which determines it is consequent upon obstruction of the air passages. That in chronic progressive emphysema this obstruction depends upon bronchitis, either humid and attended with free secretion or dry with scanty secretion. That when once emphysema is set up the dyspnœa and the necessity for forced inspiration are increased by the natural defect of expiratory power in the lungs and in certain parts of the chest nature having provided means insufficient for reducing excessive inspiratory distension to the normal and for thus emptying the lungs of residual air. That the degeneration and atrophy of lung tissue are usually dependent upon preceding over-distension, although it is possible that pulmonary atrophy may to some extent be primary.

Allow me to conclude by appropriating the words of the most ancient of the Greek philosophical poets—"These opinions have seemed to me to resemble the truth."

LECTURE III.

Delivered on March 23rd, 1899.

ON THE NATURE OF ASTHMA.

MR. PRESIDENT AND GENTLEMEN,—I propose to devote this day's lecture to a discussion of the nature of asthma. The topic you will, perhaps, consider to be almost exhausted. However, I invite you to the discussion because even if we cannot predicate all that asthma is, yet the time has come, I think, when we should finally dismiss certain opinions which have for two centuries impeded the attainment of clear notions upon the pathology of the disease.

Before proceeding to the argument it is desirable that we should come to an agreement as to the meaning of the word "asthma." It was used in a simple etymological sense until the time of our distinguished Fellow, Dr. Thomas Willis, in the middle of the seventeenth century. Asthma before his time denoted any kind of panting, gasping, pursy breathing, such as follows upon running or exertion. Hence asthma and dyspnœa were synonymous for most of the older physicians. A few, such as Celsus, signified by asthma the highest degree of dyspnœa, but this was all; asthma was never regarded as a special sort of dyspnœa. In reading the writings of the ancients we must always bear this in mind and beware of importing into their generic use of the word the special meaning which it bears in modern times. Indeed, so far as my limited reading enables me to judge, I should say that what the ancient physicians have left us concerning asthma is of very little value. It is interesting to note that those most conservative of people, the illiterate, continue to use the word in the sense of Hippocrates and Galen.

Thomas Willis was the innovator upon the doctrine of the ancients. His opinions, in their mature form, are found in the second part of his Rational Pharmaceutic, published in 1675, after his death in the same year. He says, truly enough, that the ancient physicians and also most moderns up to his time had admitted only one kind of asthma, that which he calls pneumonic asthma and which had always been deemed to be the result of the air passages of the lungs being obstructed or not open enough. It would be a more accurate expression to say that the ancients regarded all cases of asthma as pneumonic and dependent upon bronchial obstruction. From this pneumonic asthma Willis distinguishes a second kind which he calls convulsive asthma, the primary fault being in the motive organs of the lungs, to wit, in the moving fibres or muscular coats of the air vessels or in the diaphragm and muscles of the chest or in the nerves of the lungs and chest or in the origin of those nerves in the brain. There is also, he says, a mixed asthma, both pneumonic and convulsive, and inveterate asthma is usually of this kind.

You will observe that Willis's doctrine is very comprehensive and that he vaguely anticipates all the theories of asthma which have been propounded since his day. His new notion of convulsive asthma was soon laid hold of; the term "asthma" came to be reserved for the exclusive denomination of that form of the disease which was believed to be spasmodic; and this is the sense in which the word is still used by most persons even in our own day. Willis's influence upon this question of pathology has been so great that the present lecture is to a large extent an endeavour to determine whether he was the discoverer of an important truth or the parent of a delusion. A satisfactory definition of the word "asthma" will be the end of our discussion, if we succeed in attaining a clear and distinct notion of the nature of the disease, for, as Milton, writing in the spirit of both Plato and Aristotle, says: "Definition is decreed by logicians to consist only of causes constituting the essence of a thing." But meanwhile we may perhaps be able to agree upon a sort of provisional definition logically less exact. Thus, some diseases are defined, accurately enough, by means of what are called their anatomical characters, or the attendant lesions of structure, and some diseases are defined less accurately by their symptoms or the attendant lesion of function. Let us examine asthma from these two points of view.

First, what is the morbid anatomy of asthma? Here I must ask your attention to a very curious and remarkable fact. You may look through a large book upon asthma, an elaborate treatise deserving the repute it has gained, and you will find no chapter dealing with morbid anatomy. Yet surely some asthmatic patients die uncured and some of their bodies are examined, and in all the bodies examined material lesions are found; what are they? Now many of these lesions are found in some bodies only and therefore cannot have anything to do with the immediate cause of asthma. Some of these inconstant lesions are those which are apt to occur in the decline of life and it is noteworthy that Rostan, the discoverer of softening of the brain, who practised at the Salpêtrière in Paris, the great hospital for old infirm women, after asking the question—Whether the asthma of old people be a nervous affection? replies as the invariable result of his post-mortem examinations, That the asthma of old people is a symptom of an organic lesion and especially of atheroma of the aorta and of hypertrophy of the heart. Most physicians of our day would probably agree that Rostan's opinion is correct so far as its general principle is concerned—namely, that organic lesions in the chest are found—but he errs in his particulars by being far too exclusive; several morbid [illegible] more frequently met with than those [illegible] such lesions as tuberculous affections of the lungs, phthisis (active or retrograde), and acute miliary tuberculosis, though often seen in persons who are not old, cannot be deemed essential to asthma. But signs of bronchitis and pulmonary emphysema are always found; and though no one would call them the anatomical characteristics of asthma, yet the fact that they are constant demands that they should not be passed over or dismissed with the remark that they are mere complications, an obvious begging of the question. That the bronchitis of asthma should be regarded as an accidental complication and by no means as an essential element of the disease is due to the fact that since Willis's time there has always been a strong tendency to look upon asthma as something mysterious and its cause as supersensual. However, you will probably assent to the proposition that either bronchitis and emphysema constitute the morbid anatomy of asthma or it has no morbid anatomy. In either case we must reluctantly conclude that structural lesions cannot help us to a definition.

Secondly, definitions based upon symptoms or disordered functions observed in the patient during life are seldom satisfactory. In the case of asthma any definition of this kind would involve so many explanations, reservations, and distinctions that it would be nothing less than a full description of the disease. I will not attempt to succeed where all nosologists have failed and I fear that we must confess that symptomatology cannot help us to a definition.

So we will proceed to our investigation in the belief that in the case of a given patient most physicians would agree whether he were suffering from asthma or not, and that we have a pretty unanimous though an indefinable notion of the disease. Yet we must admit that the notion has been inconstant, that the extent of meaning of the word has been growing narrower and narrower. Much of what Willis called pneumonic asthma has long since ceased to be called asthma at all; much of what, by way of exclusion, was formerly deemed to be convulsive asthma is now known to be dyspnœa due to disease of the heart, blood-vessels, kidneys, to poisoned blood, and other conditions which need not be enumerated. Thus there is a risk lest asthma should become a mere *caput mortuum*, a kind of dyspnœa left when all known causes of dyspnœa have been separated, the definition of the word being purely negative, indicative of what asthma is not. But asthma is not a mere *caput mortuum*.

Inasmuch, then, as our most trustworthy guides in all the physical sciences, our senses, seem insufficient to enable us to explore the essence of asthma either in the living body or the dead, we must try to grope our way by the help of reason. And we will recur to the rival hypotheses already mentioned and will debate the question which remains much as Willis left it—namely, whether asthma is a pure affection of the nervous system or whether it is all pneumonic, due, that is to say, to gross material changes in the lungs, or whether it is a combination of the two.

I. In the first place, let us discuss the nervous, convulsive, or spasmodic hypothesis.

1. That the air-tubes possess muscular coats or moving fibres was well known to Willis. That these fibres will contract under appropriate stimulus so as to diminish the capacity of the bronchia has been demonstrated many times by experiment, the vagus being the motor nerve. But farther than this our knowledge does not extend. From the best and latest works upon human physiology we cannot learn what the use of these fibres is, nor under what conditions they contract, nor whether they contract quickly or slowly, nor whether their contraction is momentary or enduring, yet surely we ought to be able to answer these questions before we can deduce a pathology of asthma from perverted function of these fibres. The prevailing feeling is that they help the bronchial walls to resist any unwonted pressure from within—that they oppose distension of the air-tubes. But even supposing this opinion to be true we are no nearer to understanding the part which these fibres have been assumed to play in the production of asthma. We will admit that it is conceivable that their contraction may cause dyspnœa, but we must make the reservation that there is no proof of this assumption. And one thing seems to be certain—namely, that if there be such a disease as bronchial spasm, pure and simple, it must be a very rare condition, because it is inadequate to explain the catarrh which manifestly attends most, if not all, asthmatic seizures. Willis himself was far too sagacious a man not to have seen the meaning of this fact. He writes thus: "Although an asthma is sometimes simple from the beginning—viz., either merely pneumonical or convulsive, notwithstanding, after either disease hath for some time increased, for the most part it gains the other to itself, hence it may be concluded every inveterate asthma to be a mixed affection." But we have already seen good reason for doubting whether this doctrine of Willis goes far enough. The whole subject of bronchial spasm is involved in so much obscurity that we cannot admit more than that it perhaps takes a share in the production of asthma but is seldom, if ever, the chief or only cause. And we will dismiss this topic by adopting the words of an able physician of the last century, Robert Whytt, "that a true nervous or spasmodic asthma, without any other fault in the lungs than uncommon delicacy or irritability of their nerves, is a disease which we seldom meet with."

2. Let us come to the muscles of respiration. When I began to lecture on medicine at St. Bartholomew's Hospital it seemed necessary that I should expound some theory of asthma. I had been much struck by observing in bad attacks of asthma the fixed immobility of the chest in a state of the fullest possible inspiration. About the same time I came across a paper by an experimental physiologist who had found that centripetal excitement of the vagus, divided below the junction of the superior laryngeal nerve, produced tetanic contraction of the diaphragm, intercostals, and other inspiratory muscles, a state of things which is necessarily accompanied by dyspnœa, and which, in this respect, resembles the asthmatic paroxysm. And so for a year or two I taught that the fit of asthma, at its beginning at least, was due to centripetal irritation of the vagus. But maturer experience soon showed me that this fixed inspiratory distension of the chest is by no means a constant attendant upon asthmatic dyspnœa, that the inspiratory movements are sometimes free and ample enough, and thus I lost all faith in the doctrine of protopathic inspiratory spasm. Moreover, what is the evidence of inspiratory *spasm* during the attack of asthma? No doubt the chest is in a state of inspiratory distension, dilated to its utmost capacity and fixed in this position. But it is more likely that this state of things is due not to inspiratory spasm but to expiratory debility. Air is imprisoned in the lungs and no amount of forced expiration can empty them. In the last lecture I showed what a very partial process forced expiration is; over many portions of the lung it has no power. If the sufferer could empty his lungs he could fill them again; it is the deflation which is at fault and the extreme inflation is due to incessant forced inspiratory efforts to make the most of what little room for fresh air can be provided by forced expiration. This fact is very well expressed in a tale told by Dean Swift of a farmer who, when dying from asthma, said: "Well, if I can get this breath once out I'll take care it shall never get in again." And thus to conclude this topic I submit that inspiratory spasm is not the cause of the asthmatic paroxysm.

3. Again, Willis thought that convulsive asthma might sometimes proceed from irritation of the pulmonary or thoracic nerves, or of the origin of these nerves in the brain. This is one of those recondite propositions which can be neither maintained nor refuted. Contraction of the bronchial muscular fibres or of the respiratory muscles, if it play any part in the asthmatic paroxysm, may *doubtless* be due to irritation of appropriate nerves, but the muscular contraction itself has not been proved to occur, and this must be done before we need discuss its causes. The influence exerted by the nervous system upon secretion, nutrition, and the blood-supply is well known as a general fact, but any particular application of this fact to explain the pathology of asthma is at present beyond our power. Thus we have no evidence to show that asthma takes its origin from the nerves or brain.

II. But if asthma be not convulsive, we are thrown back upon the hypothesis of pneumonic asthma, for we have no third explanation before us. Let us review the argument in favour of pneumonic asthma. This argument is wholly analogical. There are several diseases which resemble asthma in certain respects, more or less. Perchance we understand the pathology of these diseases somewhat better than that of asthma. If so, we may inquire whether the nature of asthma can be assimilated to that of the diseases which it resembles. It is obvious that such an argument as this is far enough from deserving the name of induction, but we will be comforted by the saying of a wise man, that to us probability is the very guide of life. Let us enumerate and illustrate the diseases referred to.

1. *A peculiar form of acute bronchitis.*—"Last summer I

went out of town to see a little boy, seven or eight years of age, whose life was very precious to his family. He was thought to be dying of inflammation of the lungs. I found him raised up in bed, supported by his nurse, and breathing with all his might. His skin was hot, his face flushed, and his chest heaved, and his nostrils quivered frightfully. There was no croupy sound. Whatever the disease was it was all within the chest. I percussed the chest: it sounded well in every part. I listened: the air entered freely and reached every cell and vesicle of the lungs; but there was not the least perception of the natural respiratory murmur, a shrill sibilus had taken place of it altogether. Wherever you applied your ear to the chest you might fancy you heard the piping and screaming of a nestful of unfledged birds." Probably many of you will have recognised the hand of Dr. Peter Mere Latham in the somewhat rhetorical character of the description I have just read. I have set before you his description of the disease because it serves as an emphatic text and not because the affection is very uncommon; it is alluded to by many of the best authors and I myself have seen a considerable number of cases. Latham goes on to say: "I am speaking of a disease which must be distinguished from asthma according to the usual acceptation—a disease not habitual to the individual and of which, perhaps, he has never suffered a previous attack." But of course an asthmatic must have his first attack, to which Latham's criterion of habit cannot be applied, and unless he had told us that his patient had never before suffered from a similar attack and never had one afterwards his argument that the disease was not asthma falls to the ground.

Latham's patient certainly suffered from acute dry pulmonary catarrh, to use the phrase of Laennec; but in this form of disease the catarrh is not always dry; on the contrary, small mucous râles are sometimes heard all over the chest. I saw a girl, four years old, who one morning had a little cough but was quite well in all other respects. In the afternoon she suddenly became much worse and her state alarmed everybody. In the evening her distress, dyspnœa, and lividity were great; the upper part of the chest expanded considerably on inspiration, but there was at the same time much depression of the root of the neck, of the epigastrium, and of the base of the chest. All over the lungs small mucous râles were heard. Her voice and cry were natural so that there was no reason for suspecting laryngeal disease. Her temperature was below the normal. I was told that she had suffered from several sharp attacks of what had been called "bronchitis" and "congestion of the lungs"; that she had been subject to eczema all over the body; and that her father's father and brother had been "asthmatics" until they reached maturity. The very same night she improved much and next day she was comparatively well; recovery was rapid.

The chief characteristics of this form of bronchitis may be thus enumerated: the rapidity with which the dyspnœa becomes extreme; the attendant fever, little or none; the whole attack seldom lasting more than two or three days; and the great tendency to recur. In the intervals most of the patients are free from pectoral symptoms, but in some cases emphysema occurs and I have seen it well marked in a patient only three years old subject to this disease. Most of the children have suffered from eczema and most of them come from families prone to asthma, bronchitis, and gout.

When we inquire into the previous history of patients who during youth have been liable to undoubted asthma we find that in a certain number of them their disease dates from one or more attacks of this kind. And surely these attacks *were* asthma from the very first, although they were not deemed to be so at the time but were called in Latham's language "acute bronchial inflammation putting on a peculiar form and affecting a peculiar course." The bronchitis does not cause the subsequent asthma, but it is asthma; the two diseases are identical in nature and the asthma is bronchitis, although a peculiar form of bronchitis.

2. *Spasmodic croup.*—This is an old phrase now seldom used, yet I do not know that we have a better. It is not a good phrase, because it implies a hypothesis which is probably untrue. The disease is characterised chiefly by acute dyspnœa; indeed, most of the cases described by Millar in the last century under the name of "acute asthma" were cases of spasmodic croup. Spasmodic croup is not laryngismus stridulus, for the dyspnœa of laryngismus is momentary, whereas that of spasmodic croup lasts for several hours and on and off for days. Spasmodic croup is not quite the same thing as laryngitis stridula—a disease which is characterised more by dysphonia than dyspnœa. Dr. Benjamin Rush of Philadelphia was the first to apply the epithet "spasmodic" to the disease—an indication probably that he, as well as Millar, recognised a resemblance to spasmodic asthma. I enter into these details because there still exists, as there always has existed, much confusion in the use of these names. Millar's description of the disease, published in 1769, is vitiated by the fact that he does not distinguish the different kinds of acute laryngeal disease which cause dyspnœa in children. Rush's description, published in 1789, is much more precise, perhaps because more concise. He says that "the cynanche trachealis spasmodica is known (1) by coming on *suddenly* and that generally in the night; (2) by frequent and perfect *intermissions* of the symptoms for hours and in some instances for days, without the least sensible discharge from the trachea; and (3) by yielding to anti-spasmodic remedies, particularly to the warm bath." Rush had examined the body of a fatal case and had found no marks of a membrane or even of mucus in the trachea; the lungs and trachea appeared to be in a sound state.

Many persons have believed in a close analogy between spasmodic croup and spasmodic asthma. Some have even gone so far as to say that "children who have been the subjects of croup or stridulous laryngitis in their earlier years are prone to suffer from true asthma in later life," but judging from the facts of my own experience I am disposed to think that this sequence is not common. Unfortunately, the pathology of spasmodic croup is not well understood. I do not know that the glottis has ever been seen by means of a laryngoscope during the attack of dyspnœa. Could this be done it would go a long way towards clearing up the darkness which hangs over the subject. Moreover, patients when attacked by spasmodic croup seldom die and thus we are deprived of the information which minute post-mortem examination might afford. Nobody doubts that the disease implies an element of acute laryngitis, or of croup, for these two terms are almost synonymous, croup being the acute laryngitis of children. The evidence of laryngitis depends mainly upon these two facts: first, that the attack of dyspnœa is preceded for a few hours by hoarseness and croupy cough and perhaps by other signs of catarrh of the respiratory mucous membrane; secondly, that the interval between the attacks is not free from the same symptoms. Admitting, then, that there is a fundamental ground of laryngitis we must inquire in the next place into the cause of the dyspnœa, so sudden and so temporary, and here lies the difficulty. The epithet "spasmodic" begs the question by assuming that spasm of the glottic muscles is superadded to the laryngitis. But when we compare spasmodic croup with what is universally admitted to be a glottic spasm—that is to say, with laryngismus stridulus—the difference between the two diseases appears to be so great as to make us doubt whether the dyspnœa of croup can be spasmodic. In laryngismus the dyspnœa sets in very suddenly and lasts only a few seconds, for if it last longer the child will die. At any rate if the croup be spasmodic we must assume that the spasm is very incomplete and that it lasts several hours—assumptions which seem improbable. It is improbable that the spasm should be always incomplete and should never become a thorough laryngismus and thus kill the patient, whereas deaths from spasmodic croup are so uncommon that we may almost say that they do not occur. Moreover the catarrhal swelling of the laryngeal mucous membrane would render any spasm much more likely to prove fatal, and we must never forget the small size of the glottis in children when we speak of their laryngeal diseases.

But if we give up the notion of spasm are there any other explanations which we can fall back upon? Two have been offered. One was put forward first, so far as I know, by Felix Niemeyer. He supposes that viscid mucus accumulates in the glottis while the child is asleep; that this mucus becomes dry and so glues up the rima glottidis—an ingenious explanation, not wanting in plausibility, but which can be neither proved nor disproved. The chief argument against this hypothesis is found in the great resemblance between spasmodic croup and the peculiar form of acute bronchitis which we discussed just now. In both diseases, the same slight premonitory catarrh, the same sudden onset of alarming dyspnœa in the afternoon, the same speedy abatement of the dyspnœa, the same freedom from fatal results, and the same tendency to recur. Now, there is no reason for thinking that the bronchitic dyspnœa is due to accumulated mucus, still less to dried mucus; and hence we may well doubt whether spasmodic croup is due to these conditions. But yet, until we can bring our senses to bear directly upon the glottis, until we can see what actually takes place, we may admit that there is possibly some truth in Niemeyer's hypothesis. How often are we tempted to exclaim with the surgeon in the old novel, "A fig for reason, I laugh at reason; give me ocular demonstration."

The other explanation seems more probable. It supposes a sudden and temporary swelling of the mucous membrane of the larynx, such as sometimes occurs in the pituitary membrane during acute coryza when one nostril becomes suddenly blocked, and not by mucus, so far as can be made out, or at least no mucus can be expelled from the affected nostril. In the case of the nose this sudden swelling can be easily understood, for anatomists tell us that the veins of the mucous membrane over the turbinate bones constitute a cavernous structure and that the membrane in this situation is erectile. No structure of this kind has been detected in the mucous membrane of the larynx and hence the argument from analogy is weakened in a corresponding degree. In short, the opinion that spasmodic croup is due to sudden swelling of the mucous membrane depends mainly upon reasoning by way of exclusion, there being fewer objections to this pathology than to the hypotheses of spasm or of mucous obstruction.

Leaving these dry catarrhs of the respiratory tract let us turn our attention to certain catarrhs of a character exactly opposite, being attended by abundant secretion of mucus, for these catarrhs also have a close affinity with asthma.

3. *Paroxysmal coryza.*—In the first place, we will consider paroxysmal coryza or "paroxysmal sneezing" as it is sometimes called. And let me set before you a vivid picture of the disease drawn by a sufferer, a married lady, aged 29 years. I copy the exact words of a letter she wrote: "Severe cold in the head every morning for two or three hours after waking; continual running of the nose, sneezing, watering of the eyes; pocket-handkerchiefs are of no use, I have to use towels. Frequent fits of violent sneezing, perhaps repeated a dozen or 20 times. Continual rising of phlegm into the mouth in the morning on waking; often an accumulated mass of phlegm has to be got rid of. Loss of taste and smell and impaired voice in singing. The above symptoms have been present for five years, though they have increased of late. In addition the following have occasioned trouble during the past nine months: a wheezing in the chest, difficulty in breathing, or in taking a deep breath. At times this prevents me from lying down at night; at least I go to sleep in the usual way, but am disturbed three or four hours after by a feeling of suffocation and am obliged to spend rest of night sitting in a chair. This feeling sometimes comes on without any warning. Last week, when returning from a dinner party, I suddenly became oppressed in breathing, and had quite to struggle for breath for 10 minutes or so. Violent exercise, such as running and, I think, swimming, also hearty laughing, produces much the same effect—viz., a wheezing and difficulty in breathing freely. Voice in singing much fallen off. Damp weather and cold winds seem to increase the tendency." Thus far the patient's own report, to which the following facts may be added: there was a tendency in her family to asthma, eczema, and gout; she herself never had eczema, but it had appeared in several of her relatives, and also in her only child, 15 months old.

The connexion between paroxysmal coryza, asthma, and eczema is remarkable. A girl, 11 years old, had suffered from frequent attacks of asthma since the age of two years. Moreover, she had always been liable to fits of bad sneezing with running from the eyes. This sneezing was sometimes followed by asthma, sometimes not. When a baby she had eczema. In her father's family there was a tendency to eczema and gout, but not to asthma; in her mother's family there was probably a tendency to asthma. She had a younger brother who also was asthmatic, and who suffered from eczema in infancy. The girl, the brother, and the mother were all of a dark complexion. A second girl, sister of the patient, was of a fair complexion and had shown no tendency to asthma.

A boy, two years and a half old, became eczematous at six months of age. The eczema cleared off at 12 months and then he began to suffer from asthma. And mark that his attacks of asthma began with sneezing and running from the nose and that an evidence of the chronic nature of the coryza was afforded by the ill-developed condition of the bridge of his nose. But there was no obstruction to his breathing in the nose itself.

At the risk of wearying you let me give you a brief outline of another case which shows the connexion between this recurrent coryza and spasmodic croup as well as asthma. A lady, thirty years old, was subject to spasmodic croup when a child and had been liable to bronchitis all her life. Since the birth of her first child three years ago she had become asthmatic—that is to say, she was continually rather short of breath, but, more especially soon after arising in the morning or upon any sudden effort; her breathing would sometimes become very bad, she would turn blue, and the whole attack would last two or three hours; it had occasionally recurred three or four times in the day. Moreover, for two years she had been subject to attacks of sneezing almost daily, with copious distillation from both nostrils, as bad in winter as in summer. There were no objective signs of disease in the chest, nasal fossæ, or pharynx.

It is no part of my plan to discuss the relation which exists in some cases between these paroxysmal disorders and permanent disease of the nasal and post-nasal regions. But with regard to the actual attack of coryza let us observe that it is more than a mere defluxion of mucus. The mucous membrane of the nasal fossæ is swollen, especially the cavernous tissues over the turbinate bones, which swelling may be enough to make the opposite surfaces of the mucous membranes touch, and to the tickling sensation which ensues upon this contact much of the sneezing and much, in all probability, of the distillation are due. The fact that in some cases asthma very quickly follows coryza suggests the notion of a rapid spreading of the catarrhal affection downwards along the respiratory tract; what in the upper part is a paroxysmal coryza becomes in the lungs paroxysmal dyspnœa or, in other words, asthma.

4. *Paroxysmal bronchial flux.*—Closely allied as paroxysmal coryza and asthma undoubtedly are there is an obvious unlikeness between them in one respect—namely, in the amount of mucous secretion. But there is a peculiar form of what Laennec calls acute pituitous catarrh of the bronchial tubes, which more exactly resembles recurrent coryza in the abundance of the flux, its short duration, and its tendency to recur.

"A woman, aged 32 years, corpulent and of fair complexion, had suffered for some months from an obstinate cough, when one evening she was attacked by a complaint which very much resembled the paroxysm of spasmodic asthma, except that it was much more violent than first attacks of that disease usually are and that its remission was attended with a very copious discharge of frothy serum from the bronchial tubes, which was thrown up by a slight though almost continual cough." On the next morning she was much better and she soon recovered. Some months afterwards she had another attack of the same kind and about 18 months after the first attack she had a third, much more violent. "She was suddenly seized with dyspnœa attended with a convulsive kind of cough which in less than five minutes from the time of attack increased so as to produce the appearance of suffocation. Her senses forsook her, her face became livid, her extremities were cold, and the action of the heart was so much diminished that no pulsation could be felt in the wrist, and but very little in the left side. She remained in this state nearly two hours, during which time a very large quantity of frothy serum tinged a little with blood was discharged without any visible effort by the mouth and nostrils. About the end of that time some very faint and involuntary efforts to cough came on which gradually increased and with every effort large quantities of the frothy serum were thrown off; perhaps the whole quantity might amount to three or four pints. About three hours after the beginning of the attack the difficulty of breathing became very sensibly diminished and her senses were observed to return." In a few hours she had recovered so as to be much the same as she was before the seizure. After a somewhat longer time she had attained the condition of a person in the best state of health. This woman was a patient of Mr. Thomas Baynton of Bristol and her case is narrated in a book published by the well-known Dr. Thomas Beddoes of the same city. You will have observed that the profuse expectoration is said to have been "serous," but this word is no doubt used in a loose sense, for Beddoes who was a good chemist expressly says that the fluid was ascertained by careful inquiry to be mucus, and not saliva, as he at first suspected. In my first lecture on bronchitis I spoke of acute pituitous catarrh, always a serious disease; and Baynton's case was an instance of this affection but peculiar from its tendency to recur, and in this respect closely resembling paroxysmal coryza and asthma.

5 *Hay fever.*—In this place I might refer to the fact that hay fever, which usually assumes the form of coryza and lacrimation, sometimes becomes an asthma. The paroxysms of hay asthma and of what we call ordinary spasmodic asthma differ in no particular. But this topic has been so fully discussed by our late distinguished President (Sir Andrew Clark) whose opinions are doubtless well known to you all that I need not allude to them here. I will only repeat that the cause, whatever it be, of hay fever will produce ophthalmia, coryza, or asthma according to the portion of the mucous membrane which is affected.

And to sum up the argument in favour of the opinion that asthma is (in Willis's phrase) pneumonical, as distinguished from the convulsive form of the disease, the assumed bronchial obstruction being due, not to *any sort of spasm*, but to what he calls an afflux of humours upon the air passages. We have seen that there are *five or six* affections of the respiratory tract which are closely allied to asthma and which may be said *to constitute, together with asthma, a* special class of diseases, characterised as follows. They set *in suddenly, they speedily reach their highest point of* severity, their duration is short, they are apt to recur, and *in the intervals* the patient *is more or less free from signs* of disease until the catarrh becomes chronic. The tendency to the *disorders is hereditary* and runs in *families*; many patients manifest a tendency to two or more of these complaints. If the *force* of these analogies be admitted we may carry the argument farther and observe that all these diseases are catarrhal. Now catarrh implies two conditions—namely, increased secretion and swelling of the membrane, but as matter of fact neither of these conditions is constant The defluxion or increased secretion may be absent or at most may be very small, and this constitutes Laennec's dry catarrh. The swelling is more constant, at least in acute catarrh; in paroxysmal coryza, which has so close an affinity with asthma, the swelling can be seen; moreover, both defluxion and swelling occur with great rapidity. The two concomitants of catarrh will explain the most important symptoms of all the disorders in question, including asthma.

If we consider the catarrhal tendency to be due to an inherent delicacy or vulnerability of the mucous membrane, a tendency usually inherited, we seem to be able to understand the reason of the fact that asthmatic persons during childhood are so often liable to eczema, which may be deemed to be indicative of a similar condition of the skin.

In the earlier part of the lecture we arrived at the conclusion that the doctrine of a spasmodic asthma is very imperfectly supported by *facts* and now the argument has led us to believe that all asthma is merely a peculiar form of bronchitis *and that there is no need for any hypothesis of spasm in* order to explain the phenomena of the disease. Should it be objected that bronchial *spasm may* possibly aggravate the effects of catarrh we may appeal to the philosophic law of parcimony—*Entia non sunt multiplicanda præter necessitatem.* You know that this is not a new doctrine. Many years ago it was maintained very ably by Beau. Sir Andrew Clark arrived at the same conclusion by a different path—by noting how one and the same cause, hay fever, produces sometimes coryza, sometimes asthma, and sometimes both together. Which element of the catarrh, defluxion or swelling, obstructs the tubes is a question which naturally arises. The interesting observations of Lefèvre, published more than 60 years ago, upon the expectoration of peculiar mucous cylinders, which he compared to cooked vermicelli, towards the end of an asthmatic attack render it very probable that both secretion and swelling concur to obstruct the bronchia. But there remains another and much deeper question which concerns the asthmatic tendency—in what does it consist? Why are some persons prone to asthmatic catarrh and others not? Why does the disposition run in *families*? What is the bond which in so many cases connects the several diatheses of asthma, eczema, and *gout*?

For the solution of such problems as these and for the advancement *of all medical learning, may a succession of* men like Harvey and Willis never be wanting to our venerated College.

BLACKWATER FEVER.[1]

BY W. H. CROSSE, M.R.C.S. ENG., F.R.G.S.,

CONSULTING MEDICAL OFFICER TO THE ROYAL NIGER COMPANY,
CHARTERED AND LIMITED.

IN venturing to bring under notice the disease called "blackwater fever" or "*hæmoglobinuric fever*" I would submit that we are dealing with a subject of vital importance as regards our colonies. It is admitted that this complaint is the cause of more deaths and invaliding than all the other diseases from which Europeans suffer in West Africa, and the same remark applies to the opposite side of the continent. Koch, for instance, states that this disease creates the greatest havoc *amongst Europeans* in German East *Africa.*[2] The disease, however, is not confined only to Europeans, for on the Congo railway many of the Chinese labourers died from it. It has been considered to be rare amongst Africans; however, I am told that many died from it while working on the Panama Canal; and recently, we are *informed,*[3] *there has been a serious outbreak of it* among the blacks in the Cameroons, the disease specially attacking *those who had come to the coast from the interior.* When I first went to West Africa in 1886 blackwater *fever was a complaint about* which very *little had* been written and the ordinary English text-books did not even *mention the existence of such a disease.* Dr. C. H. Eyles had published a brochure on the fevers of the Gold Coast[4] in which a considerable amount of information is given about the disease, and an interesting account of a case of blackwater fever was published by Dr. Easmon in the *Medical Times.*[5] In 1892 I published a small book on the malarial fevers of the Niger, of which a large portion was devoted to this subject.[6] The study of this complaint received a considerable impetus when Dr. Patrick Manson, on March 15th, 1893, read before the Epidemiological Society an interesting paper on African hæmoglobinuric fever.[7] Since that time more and more attention has been given to the disease and more especially quite recently on account of the statement made by Koch that blackwater fever is due to quinine poisoning.[8] I have already attempted to answer Koch's contention that blackwater fever is simply quinine poisoning in a paper read before the Guy's Hospital Physical Society in October last.[9] I have also dealt to some extent with the pathology of the disease, as evidenced by a case which I saw in England with Mr. Wooldridge of Camberley, in a paper which I read with Mr. Pakes before the Pathological Society on Dec. 20th, 1898. I hope here to review the subject and to lay before you a definite statement as to the opinion which I hold with regard to its pathology, causation, and treatment. I cannot let this occasion pass without mentioning how deeply I am indebted to *Dr.* Washbourn, who years ago urged me to write on this subject and showed me the first malarial parasites *I had seen.* I *also take this* opportunity of thanking Dr. R. Howard who has just started for East *Africa, to whom I am indebted for much help in* this paper. On account of his special training we may look *to him* in the near future for valuable information about the disease under consideration.

DEFINITION.

By blackwater fever, or hæmoglobinuric fever, I mean a febrile disease of malarial type characterised by hæmoglobinuria, jaundice, and vomiting. The name, "blackwater fever," was given on account of the darkness of the urine which could scarcely fail to attract the attention of the sufferers. The colour of the urine is due to the presence of hæmoglobin or methæmoglobin and not of blood, although in some attacks *nephritis may occur* and *real hæmaturia* result. Blackwater fever should not be used to include those attacks of malaria in which nephritis is a primary symptom and which are attributed to plugging of renal capillaries by malarial parasites. My clinical descriptions will be based on my observations of the fever on the West Coast of Africa during nine years' service in the Royal Niger Company, in which time I saw about 100 cases.

DISTRIBUTION.

Since attention has been drawn to blackwater fever the disease has been recognised in several parts where it was formerly considered to be unknown or, at any rate, extremely rare. For instance, when I had one of my earliest attacks on the Niger the medical man who attended me did not recognise my illness as blackwater fever and mistook the colour of the urine for that due to bile. Sometimes when hæmoglobin and albumin were recognised they were thought to be due to a renal hæmorrhage complicating the malarial attack and until quite recently the disease was often spoken of as hæmaturic fever. Many cases have been called yellow fever. I do not think the disease is a new one. Manson states that it was first described by naval surgeons stationed at Nossi Bé, a French settlement off the North-west coast of Madagascar.[10] Plehn quotes Bérenger-Féraud as stating that the disease existed in West Africa in 1820. He further says that it can first be proved to have become prevalent about 1850.[11] The first fatal case on the Gold Coast is believed to have taken place in 1832. It is common throughout West Africa, including the Gold Coast, Sierra Leone, Nigeria, Cameroons, and the Congo and Gaboon regions; it is also common in East Africa—for example, in Uganda, German East Africa, and in the Zambesi districts. I have seen one patient who seems to have suffered from the disease in Somaliland. It has been considered very rare in India but it is probable that it has been overlooked, for recently 11 cases have been described by Mr. Arthur Powell as occurring in Assam and which he states were "identical with the fevers I have seen in those returned from the Gold Coast."[12] It is frequent in certain tropical parts of North and South America and in Cuba. The disease is said by Manson to have been epidemic among the labourers employed in making the canal through the Isthmus of Corinth. Cases are reported from China, and Plehn states that its existence has also been proved in Italy and Sicily, New Guinea, and Java. The disease is stated to be becoming more prevalent in Africa. This cannot be entirely accounted for by the increase in the white population. I attribute its increase in certain parts of West Africa partly to the fact that as the country is becoming more opened up the traders live more on shore than they formerly did, for in the old days trade was in parts of the Niger Delta carried on on the hulks which were stationed near the mouths of the river for that purpose. Another reason appears to me to be the fact that stores, houses, factories, and wharves have to be erected, which of course necessitates considerable disturbance of the soil; in addition to this, large plantations are being formed now that it is recognised that West Africa is, amongst other things, a capital coffee-growing country.

It may not be out of place here to quote from my own lecture[13] the following: "Some will ask, Why has blackwater fever become so common recently? The first case on record in the Niger Territories is, as far as I know, my own, some 10 years ago. The first case in the Niger Delta is said by some old coasters to have occurred in 1882. It seems to me that since we have begun to turn up virgin soil for coffee and other plantations that the disease has become common. When I went to the Niger in 1886 there was not a single plantation. Very soon large plantations were started. I believe I was the first to start them, for I took out with me a great many seeds of English fruit, and soon after these were planted an experimental plantation was started, first at Asaba, then at Abutshi, some 150 miles up the river. It is significant that our first three gardeners died from blackwater fever and that for some considerable time cases only occurred near the plantations, and as plantations became more common so the disease spread to the other stations in the territories."

Outbreaks of blackwater fever have been specially noted when the dry season has been prolonged and very hot and when, therefore, lagoons and ponds which have been long covered with water have been dried up; the same thing has been observed when the rainy season has been broken up by long spells of drought. Easmon, in 1881, had four cases of blackwater fever under observation and attributes these attacks in some degree to the extreme drought of the season, drying up the extensive Quettah lagoon which had been covered with water for twelve years.[14]

CLIMATE AND CONDITIONS OF LIFE.

The River Niger, near the sea, forms an enormous delta and opens by many mouths into the Gulf of Guinea; this delta which consists of mud and sand is covered with mangrove forest and jungle; it is divided and subdivided in every direction by creeks, and as the tide goes out the shore shows itself as a foul mass of mud through which pour turbid streams on their way to the sea. The level of the land is so slightly above that of the water that it is being constantly washed away and where Europeans settle the ground is protected by pegging it round with sticks and constantly backing them up with heavy clay in order to prevent the sea from washing it away; to act as a further protection old hulks and lighters are run close to the shore and left there till they sink or fall to pieces. The earth is constantly damp, for the subsoil water is close below its surface and the ground is itself frequently drenched with heavy rains. The average temperature is about 80° F. and the difference in 24 hours is often less than 10 degrees; the air is highly saturated with moisture, for the rainfall is very heavy, being between 125 and 150 inches in the year. Sometimes in one day it is enormous. For instance, on turning to one of the meteorological reports of the Royal Niger Company, kindly lent to me by Sir George Goldie, the Governor, I find that at Akassa (the port of the Niger) on May 22nd, 1887, it was 4·030 inches, and on May 27th, 1888, it was 5·905 inches.

Owing to the great amount of moisture a mist frequently hangs over the land like a pall, whilst keys rust in one's pocket and boots put away for a day or two become covered with a heavy mildew. Periods of rain are interrupted by times of excessive drought, during which the ground splits and cracks in all directions, exhaling a peculiar stench from the decaying vegetable matter with which it is so largely impregnated. When to the above is added the fact that in the delta regions it is often difficult to obtain fresh meat and always impossible to get a supply of fresh vegetables it will be seen that the conditions of life are not favourable to Europeans. Finally, when we consider that mosquitoes and other blood-sucking insects abound it will be conceded that malarial germs here find a congenial home and in the debilitated Europeans a soil suitable for their growth; and it will not cause us surprise when we find that these regions are prolific in cases of malignant malaria. Farther inland, say 150 miles up the river, the same conditions largely prevail, for the land, alternately drenched and scorched, is covered with a rank jungle. In the wet season the Niger is a splendid rolling river, in parts a mile broad, and capable of bearing sea-going vessels of deep draught; but in the dry season it diminishes so much that its bed is exposed in many parts and it is with difficulty that a small vessel drawing four feet or five feet of water can be navigated through its narrow channels. At the height of the wet season the land is in many parts inundated with water; native huts are flooded and are frequently swept away. I have often seen a native fishing from a canoe in his own house. As the river falls its banks are exposed to the fierce sun and at low water they may be 26 feet or 30 feet high. Away from the river large ponds, lakes, and lagoons are found and these wholly or partially dry up in the hot weather. The natives live in mud houses, under the floors of which they frequently bury their dead. To build their houses it is necessary to dig huge pits in order to obtain the clay suitable for the purpose; these pits are not filled up, therefore they are found all about their towns; the rain partially fills them with water, which stagnates, and low forms of vegetation luxuriate within them; in these pits all kinds of filth are thrown and here snakes, mosquitoes, and other abominations find a pleasant retreat and a quiet breeding-ground.

I have said enough to show why malaria runs riot in these regions; one other factor, however, must not be omitted: I refer to the "conscientious objector"—and he is also in evidence here—for many of the Europeans have an abiding faith in the pernicious effects of quinine in all malarial cases, whether slight or severe. I have a patient of this class now under my care. Recently he was invalided home on account of repeated attacks of malaria; his medical man supplied him with the quinine necessary for the voyage, but a fellow passenger knew better than the medical man and he and some others persuaded the sufferer to take five grains of quinine every third day instead of twice a day as had been ordered. When I saw the man he was in apparently a hopeless condition and ring-shaped parasites and crescents were plentiful in his blood. He took quinine in full doses and in four days he was able to sit up in his front room. The poor fellow was very grateful, and as he shook hands with me he said that he knew I had had to try the quinine kill-or-cure remedy and he was glad I had not given him blackwater fever. Of course it will be understood that in the higher lands of Nigeria the conditions of life are much more favourable to Europeans.

DIAGNOSIS AND SYMPTOMS.

Besides the hæmoglobinuria which gives the name to this disease there are three other symptoms which are constantly present. Reports of cases are now frequent in which one or other of these other symptoms is absent; such must be accepted with the greatest caution. However, it must not be forgotten that the same disease often varies in its intensity and symptoms in different parts of the world and in different patients and that it is modified by the patient's condition of health, his food, his surroundings, and many other things. There are, in fact, four cardinal symptoms—viz., (1) fever; (2) hæmoglobinuria; (3) jaundice; and (4) nausea and vomiting of bile. We will now consider these symptoms in detail.

Fever.—I contend that the hæmoglobinuria comes on during an attack of fever clinically resembling an ordinary malarial fever. Often the temperature is not taken before the hæmoglobinuria has been observed; the patient feels, perhaps, that he has on him a more or less severe attack of fever but does not trouble much about it, expecting that he will pull through all right as he has frequently done before. Usually the first warning is a sharp rigor on the second or third day of the fever; the patient's temperature will rapidly rise to 103° F. or higher and the next specimen of urine which he passes will be found to be hæmoglobinous. Coincident with this the temperature frequently falls, often to normal; this drop I regard as probably due to the virtual hæmorrhage and wholly analogous to the fall which accompanies hæmorrhage in typhoid fever. It has not the importance which is often given to it and certainly does not justify the argument used by some that blackwater fever is never malarial because the temperature is not maintained for two or three days, as is often the case in ordinary African malaria. Subsequently to the drop the temperature may rise, but not as a rule very high. In fatal cases in which collapse is present the temperature is often subnormal unless it rises owing to complications. In some cases, though, there is a daily remission, yet the temperature continues to rise till death closes the scene.

Hæmoglobinuria.—The colour of the urine may be any shade between light red and that of porter, depending partly on the amount of urine passed and partly on the quantity of colouring matter present. This is undoubtedly in most cases either oxyhæmoglobin or methæmoglobin or both. Thayer, however, states that the colouring matter is always present in the form of methæmoglobin.[15] Albumin is, of course, always present; as a rule bile is absent though it is somewhat difficult to recognise in the presence of hæmoglobin; and many observers—e g., Plehn—state that they have noted it. On shaking up the urine the froth is pink in colour. I note that Thayer mentions the greenish froth of the urine of patients suffering from hæmoglobinuric fever; if there is one thing of which I am certain it is that the froth of the urine of blackwater fever is in West Africa always, as far as I have seen it, of some shade of red. On microscopical examination none, or only very few, red discs are to be found, but hæmoglobin casts of the renal tubules are plentiful. Nothing else abnormal is constantly found; of course, as in all albuminous urine, bacteria and torulæ grow freely if it has been allowed to stand for any length of time. Blood discs may be present after a day or so as a result of nephritis set up by the hæmoglobinuria.

Jaundice.—It is to be noted that although jaundice is present bile is usually absent from the urine. Copeman states that bile is either entirely absent from the urine or is present in an insignificant amount;[16] at the same time there is plentiful elimination of it in the vomit and the motions. There are none of the usual accompaniments of jaundice, such as slow pulse, itching skin, &c. The jaundice appears to me always to precede the hæmoglobinuria. Bérenger-Féraud says that icterus appears at the onset of the attack.[17] Easmon in one of his cases[18] notes at 9 A.M. that the urine was only highly-coloured and that there was slight jaundice, and that about 3 P.M. the urine was black; and in his paper on the Nature and Treatment of Blackwater Fever (p. 2) he says that the jaundice, which is uniform, is seen from the very first onset of the disease. Now we hear of cases in which jaundice appears only after the hæmoglobinuria. Up to the present I agree with Easmon on this point; but the study of the disease is so recent and the reported cases are so few that I am quite willing to admit that on this, as on many other points in this interesting complaint, further knowledge may cause the older observers to make some modifications of their opinions. The jaundice, as a rule, deepens while hæmoglobinuria is present and gives to the patient a greenish-yellow appearance.

Nausea and vomiting.—These are the most distressing symptoms; they are usually very persistent and hence give much trouble in the administration of drugs and nourishment. The colour of the vomit is usually characteristic, it being of a bright or olive-green colour. Cases are reported without any mention of green vomiting, but I can only say that I have found it to be an almost constant symptom in bad attacks and something of a guide as to the severity of the complaint. I have recorded a case (Case 12) in which there was little or no vomiting.[19] This symptom is regarded as constant by Bérenger-Féraud. He says: "The vomiting is bilious, of a decided green colour; it is a constant symptom at the outset of an attack. It stains the linen of a bright green and when collected in a basin is of a beautiful green or olive colour."[20] In Easmon's case before referred to he states that the patient vomited a clear green fluid which contained particles like chopped spinach. Fisher[21] states that vomiting does not appear if the patient has an empty stomach or if he has some hours previously to the hæmoglobinuria been put on a milk diet; I cannot say that this has been my experience.

Other symptoms.—Amongst the other symptoms which go to make up an attack of blackwater fever the following may be mentioned. Frequently there is severe headache, also pain in the loins and limbs. Patients often complain of numbness of the extremities. Usually there is also pain in the liver and spleen; both these organs are often enlarged. Constipation is usual at the outset of the complaint, but later there is danger of severe diarrhœa, especially if too active purgation has been employed; when this occurs it will, of course, increase the patient's exhaustion and cause special symptoms of its own, such as colic, straining, and smarting of the anus. In one of my cases the motions were frequent and towards the end they became reddish in colour—due, I take it, to hæmorrhage in the bowel; melæna is said occasionally to have occurred. Often there are oppression at the chest, sighing and shallow breathing, due, I think, to the patient's anæmia. The persistent vomiting at times causes severe gastralgia and general discomfort, and to it, no doubt, is due the excessive thirst which is so frequent. Finally, in many of the worst cases, continuous hiccough is present.

(To be continued.)

VACCINATION PROSECUTIONS.—At the meeting of the Chipping Sodbury Guardians held on March 17th a resolution was read from the parish meeting recently held at Frampton Cotterell protesting against the vaccination officer instituting prosecutions without the consent of the guardians. On the proposition of the chairman (Sir Gerald Codrington) it was decided to send an answer stating "that the consent of the guardians is not required before proceedings are taken by the vaccination officer."

A CONTRIBUTION TO THE STUDY OF APHASIA.

A CASE IN WHICH COMPLETE DESTRUCTION OF BROCA'S CONVOLUTION BY A NEOPLASM IN A RIGHT-HANDED PERSON PRODUCED NO APHASIA.

By JAMES S. COLLIER, M.D., B.Sc., M.R.C.P. Lond.,
SENIOR HOUSE PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, BLOOMSBURY.

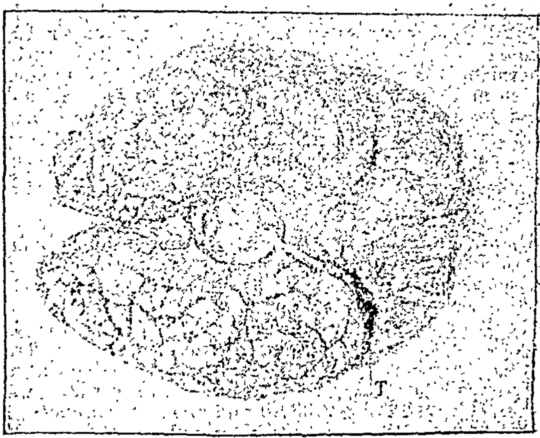
The following case is of great interest as it exemplifies the activity of the glosso-kinæsthetic centre in the right rather than the left third frontal convolution in a right-handed person. I am indebted to Dr. Bastian for permission to publish the notes of this case and to Dr. Risien Russell for the pathological report.

A woman, aged 23 years, unmarried, was admitted on May 23rd, 1897, to the National Hospital for the Paralysed and Epileptic as an out-patient under the care of Dr. James Taylor. There was no family history of fits or nervous disease; her mother had died from cancer. Her previous health had always been good, with the exception of an attack of pleurisy three years before her admission to the hospital. There was no history of infantile convulsions and she had never had any trouble with her speech. She was right-handed and wrote with her right hand, and she was skilful in playing the mandoline. No members of the family had been known to be left-handed. The history of the patient's illness was as follows. In May, 1896, when she was walking out with her sister she suddenly fell down and was unconscious for a few minutes. There was no warning of the attack. Her face was pale but she was not convulsed, nor did she bite her tongue or pass urine during the fit. During the next fortnight she had two fits of a similar nature, but in the second fit the teeth were clenched and she was slightly convulsed all over and foamed at the mouth. Since that time she had no more fits, but she had frequent sudden attacks of giddiness, pallor, and faintness. No speech defect was noticed after any of these attacks. On examination Dr. Taylor found no signs of organic disease. The patient was treated with bromides and the attacks of giddiness became much less frequent. She regularly came to the out-patient department for the next 18 months, during which time her health was good and she continued her work. During the month of October, 1898, she was noticed to be a little dull mentally and she complained sometimes of slight headache. On Nov. 8th she was noticed by her sister to mumble in her speech and to use wrong words for the period of half an hour. For instance, she called the fire register in her bedroom the "directory" and spoke of the incandescent gaslight as the "metropolitan gaslight." This affection of speech completely passed off in half an hour and was not again noticed. On Nov. 12th she went to a theatre apparently in excellent health and on returning home she entertained her family by singing and playing the mandoline. The next morning she was noticed to be very heavy and somnolent, but she did not complain. This somnolence deepened and she was admitted into the National Hospital for the Paralysed and Epileptic as an in-patient on Nov. 14th and was placed under the care of Dr. Bastian.

On examination the patient was found to be a well-nourished, healthy-looking, rosy-faced girl. She was evidently very ill physically and she lay in bed in a semi-comatose state and never moved a muscle unless roused. Her breath was offensive and her tongue was furred. When she was roused she kept on saying "Oh dear" in a sighing voice. She obeyed simple orders and answered simple questions if they were repeated several times. During the examination she said spontoneously, "Why can't you leave me alone? Let me go to sleep, I'm all right." There was no word-blindness and she could write her name, but required continuous exhortation during the process. She could only be induced to take liquid food with great difficulty. There was no hemianopia. The optic discs showed recent optic neuritis and the surface of either disc was seen with a + 3 dioptre lens. There was complete palsy of the right sixth nerve and nearly complete palsy of the left sixth nerve. The left lower face did not move quite so well as the right. Motion and sensation in the trunk and limbs were natural. There was neither headache nor cranial tenderness. The knee-jerks were not exaggerated, the left being rather the more easily obtained of the two. The wrist and elbow jerks were brisk and equal. The plantar reflexes showed a flexor response on either side. Examination of the thorax and abdomen showed no abnormalities. After her admission into the hospital the stupor gradually deepened and the breathing became stertorous. The temperature ranged between 100° and 102° F. She died from respiratory failure seven days after admission without the manifestation of any further physical signs. A pathological examination was made by Dr. Risien Russell.

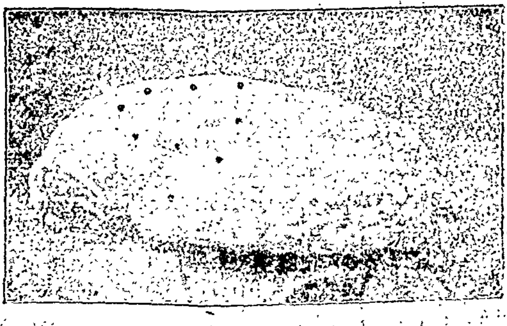
The necropsy was performed 12 hours after death. On removing the brain the dura mater was found adherent to the anterior part of the left temporo-sphenoidal lobe over an area of the size of a threepenny-piece. The leptomeninges at the base of the brain showed considerable old patchy thickening. There was slight recent meningitis over the posterior extremities of the second and third left frontal convolutions, and over the anterior part of the left temporo-sphenoidal lobe. The cortex of the posterior end of the third frontal convolution, including that part between the ascending and posterior limbs of the Sylvian fissure and the contiguous part of the left temporo-sphenoidal lobe, presented a grey jelly-like aspect suggesting the presence of a glioma in that region. To the touch this part of the cortex was elastic and yielding, suggesting the presence of a cystic condition. The inferior aspect of the brain showed a growth filling up the left Sylvian fissure and growing from the posterior part of the orbital lobule. Its projecting part was semilunar in shape, about an inch in its transverse extent and a third of an inch in its antero-posterior extent. The anterior border of the growth was parallel to the anterior border of the left temporo-sphenoidal lobe and it extended in the Sylvian fissure from close outside the outer root of the left olfactory tract to the bifurcation of the Sylvian fissure. Figs. 1, 2, and 3 show the position of the growth upon the surface of the brain.

Fig. 1.



Inferior aspect of the brain, the cerebellum and pons having been removed. (The distortion of the right occipital lobe was the result of pressure during the process of hardening. T. Tumour projecting in Sylvian fissure.)

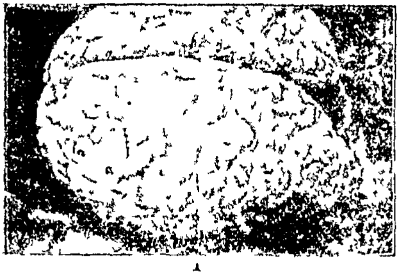
Fig. 2.



Lateral aspect of the left hemisphere. The surface-extent of the growth has been indicated by black-headed pins.

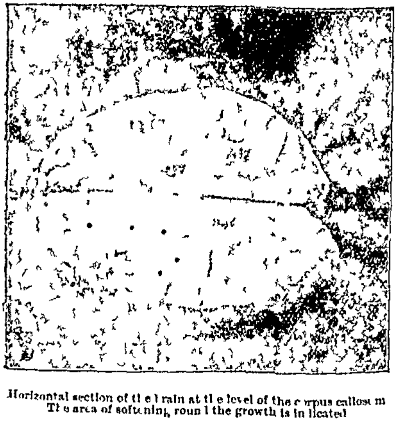
The brain was hardened in formalin and subsequently two horizontal sections were made, one at the level of the corpus callosum and the other at the level of the upper border of the anterior commissure. The growth was found to involve the inferior margin of the left second frontal convolution at about its middle, the whole posterior part of the left third frontal convolution, the posterior part of the orbital lobule, and to a small extent the anterior gyrus of the island of Reil. It crossed the posterior limb of the Sylvian fissure about a centimetre from its commencement and involved the anterior part of the first left temporo-sphenoidal convolution. The measurement of the growth in its maximum vertical extent was five centimetres; in its coronal extent it was 3·7 centimetres, and in its sagittal extent it was three centimetres. The ascending frontal convolution was not involved. The right third frontal convolution and the right hemisphere appeared perfectly healthy. The growth presented a gelatinous semi-transparent appearance on section, and there were several small cysts with clear jelly-like contents of from two to four millimetres in diameter in its upper part. There were several hard white nodules in the growth, the largest being of the size of a pea. For some distance round the growth the white matter of the centrum ovale was much softer than elsewhere. The extent of this condition is shown in Fig. 4. The other organs of the body presented a normal appearance. On microscopical examination the growth was found to consist of small round-celled tissue, the cells being densely aggregated around the blood-vessels, which were greatly thickened. Throughout the tissue were numerous large cells which stained very faintly. Several large patches of substance presenting a caseous appearance and which did not stain were seen in each section and corresponded with the hard nodules seen with the naked eye. The appearances suggested a long-standing and slowly-growing neoplasm.

FIG. 3.



The left hemisphere seen from the side and above. The position of the growth is indicated by black-headed pins. A, Fissure of Rolando.

FIG. 4.



Horizontal section of the brain at the level of the corpus callosum. The area of softening round the growth is indicated.

So far as I am aware no case of the same kind as this one has been previously recorded. It proves the possibility of *the fortuitous major activity of the glosso-kinæsthetic centre* in the right third frontal convolution in a right-handed person. It also shows *that right-handedness does not* necessarily involve the major activity of the third left *frontal convolution for the production of articulate speech.*

It has been suggested by Byrom Bramwell[1] that in some *right-handed persons whose ancestors were left-handed* the glosso-kinæsthetic centre may possibly be situated in the right hemisphere. *I obtained in this case a most complete* account of the family history and there was no instance of left-handedness *in the family.* The presence of a pathological condition in the usual position of the glosso-kinæsthetic centre (the *left* third frontal convolution), together with a completely functioning glosso-kinæsthetic centre in another part of the brain (the right third frontal convolution), strongly suggests a causal relationship between the two. It may be argued that in this patient in early life the left third frontal convolution was the seat of some developmental or acquired defect which caused the right third frontal convolution to take up the speech function when that was learnt and which predisposed to the occurrence of the new growth, but there was no pathological evidence in support of this view. Such a lesion in early life would in all probability have caused some atrophy of the affected cortex and asymmetry of the convolutions and in this case the convolutions were quite symmetrical upon the right and left sides. Nor was there any evidence of any trouble with the speech function in early life. She had begun to talk at the age of 18 months and had learnt to talk quickly and well. It is inconceivable that the glosso-kinæsthetic function could have been taken up by the right third frontal convolution *pari passu* with the devolution of the left third frontal convolution owing to the presence of a slowly growing neoplasm without some speech defect being at any time noticeable. The history of the patient both previously to and during her illness was obtained in the greatest detail from those who were constantly with her and no speech defect had been noticed. The facts of the case suggest that the unusual location of the leading or active glosso-kinæsthetic centre and the presence of a neoplasm in the left third frontal convolution were simply coincident and that the right third frontal convolution had in this patient always performed the function of a glosso-kinæsthetic centre.

Left-handedness does not always transfer the leading speech centres to the right side of the brain, as exemplified in Dickinson's[2] case and Wadham's[3] case, and notwithstanding *the immense influence of heredity* right-handedness may in rare cases be associated with leading speech centres in the right hemisphere, as I think this case proves. Bastian[4] has suggested that a similar location of the glosso-kinæsthetic centre may have been present in Barlow's[5] case, in which after an attack of right hemiplegia and aphasia the power of speech returned on the tenth day and the patient had apparently recovered from his symptoms in a month. A second attack three months later of left brachio-facial monoplegia deprived him entirely of his speech. Symmetrical lesions of about the size of a shilling were found in each hemisphere involving the posterior end of the third frontal convolutions. In a case recorded recently by Byrom Bramwell[6] a similar explanation would accord very well with the facts of the case. In discussing his case he inclines to a different explanation. Thus he suggests "that in very rare instances, of which the present case is an illustration, the functional activity and educational endowment of the right third frontal convolution are so perfect that the speech function can be immediately taken up when the left motor vocal speech centre is acutely and completely destroyed." My suggestion, is only one step farther than this and renders the explanation of the case less difficult. I would suggest that the transient speech defects in these two cases were of the same nature as are the speech defects sometimes seen in cases of left hemiplegia in right-handed persons.

[1] Lectures on Aphasia, Edinburgh Medical Journal, 1897, vol. ii.

[2] Bastian: Aphasia and other Speech Defects, 1893, p. 90.

[3] St. George's Hospital Reports, 1868, vol. iii., p. 245.

[4] Loc. cit., p. 322.

[5] Brit. Med. Jour., July 28th, 1877.

[6] Brain, 1893, p. 343.

The incompleteness of the notes upon speech defect in this case is due to the fact that it did not present itself as a case of aphasia. The handwriting was tested, as it is a routine practice in the National Hospital for the Paralysed and Epileptic for each patient to write his name in the notes. Word vision was tested in the routine examination of eyes presenting optic neuritis.

A PRELIMINARY NOTE UPON CERTAIN ORGANISMS ISOLATED FROM CANCER AND THEIR PATHOGENIC EFFECTS UPON ANIMALS.[1]

BY H. G. PLIMMER, M.R.C.S. ENG., F.L.S.,
PATHOLOGIST AND LECTURER ON PATHOLOGY AND BACTERIOLOGY, ST. MARY'S HOSPITAL.

DURING the past six years I have been studying the cell-inclusions which are found in cancer and their relation both to the origin and course of the disease, and for this work I have had to examine 1278 cancers taken from various organs and parts and of all possible varieties. Out of this large number of cases there have been a few—nine in all—in which the cell-inclusions have been extremely numerous, so that at the growing edge, and even far into the tumour, scarcely a cell could be found without an inclusion, sometimes with as many as 36 even of these inclusions in one cell, and these bodies have been similar to those which Metchnikoff, Ruffer, and others, as well as myself, have regarded and described as parasites standing in causal relationship to the disease. In two out of the nine cases mentioned these bodies have been present in enormous numbers, and I have succeeded in isolating from the last of these remarkable cases an organism which is pathogenic in a peculiar manner to certain animals and whose virulence I have been able to keep unimpaired for some months.

PREVIOUS WORK ON THE EXPERIMENTAL PRODUCTION OF TUMOURS IN ANIMALS.

The only work, I think, that needs mention here in connexion with this heading is that of Sanfelice in Cagliari and of Roncali in Rome. Sanfelice has produced tumours in animals with organisms which he isolated from infusions of various fruits, and they both have isolated organisms from cancers, which I believe from their descriptions—I have not seen their cultures—are morphologically somewhat similar to those I am about to bring before you. But Sanfelice's organism appears to have been very difficult to isolate in a virulent form from human cancer and to keep virulent, so that in his last paper[2] he treats only of the organisms derived from fruit infusions and of their effects upon animals. Most of the statements are doubted by the German pathologists, including such a good observer as Baumgarten, but from my own experience I do not find any reason to doubt any of Sanfelice's statements, and I think that he deserves the greatest credit for removing the study of the etiology of cancer from the histological to the experimental region of work.

ON THE METHOD OF ISOLATION ADOPTED.

The cancer from which the organisms I am about to describe were isolated and with which my experiments have been made was taken from the breast of a woman, aged 35 years; it had a history of only two months' duration and it was growing rapidly at the time of the operation. Immediately after removal I examined a fresh scraping and finding such an extraordinary number of the bodies I have mentioned in the cells I cut, with all possible precautions against contamination, with a carefully sterilised knife, very thin slices from the growth which I placed with a little of the juice scraped from the cut surface in a flask containing the following liquid, which was of course carefully sterilised. This medium consisted of an infusion made from cancer, just as the ordinary beef infusion is made, to which was added, after careful neutralisation, 2 per cent. of glucose and 1 per cent. of tartaric acid. This medium was the outcome of many trials with all kinds of mixtures and I tried it in this case as I had already got similar organisms to grow in it from two previous cases but they had no pathogenic properties, and this, I think, was due to the omission of the next step. This medium, too, is particularly useful, as hardly any bacteria, however hardy, will grow upon it. Then, remembering that in the body these organisms were under anaerobic conditions, I exhausted the air from my flasks and passed hydrogen into them and finally sealed them up. This I have found is of great importance as regards the maintenance of the virulence, and I find consequently that there is no falling off in the virulence of my cultures which are as active now as they were four months ago. Five flasks were made in this way, but in spite of precautions two became contaminated with moulds; in the other three, however, I got after from three to five days a pure culture of the organism described below has been kept growing in this and various other media ever since.

MORPHOLOGY AND RELATION TO MEDIA.

The organism is apparently a saccharomyces, but I am informed that, according to some authorities, such as De Bary, Cuboni, and Duclaux, the saccharomycetes are nothing but the developmental stages of fungi which really belong to either the phycomycetes, the ascomycetes, or the basidiomycetes. Moreover, they state that in some species of mycelium-forming fungi, single parts, especially conidia, can grow in the saccharomyces form on certain nutrient media, so I will not attempt to locate this organism at present. Sanfelice and Roncali, however, definitely state that the organisms they have isolated are blastomycetes.

When grown in the medium described these organisms produce a cloudiness which becomes visible in about 48 hours and increases till about the sixth day, when the growth sinks to the bottom, the medium then becoming clear; no scum or pellicle is formed. When grown on this medium solidified with agar the organisms form small round colonies which remain separate. After some weeks the colour, which was originally white, becomes yellow. The colonies do not attain at any time a great size.[3] Gelatin is not liquefied, but the growth on this medium is never luxuriant. On potato a thick white layer is formed which in about two weeks will cover the entire surface, changing then to a yellowish-brown colour. They will grow aerobically, but not so well, at any rate at first, and they lose their virulence in a short time if continuously grown in this way. Microscopically they are round bodies, frequently growing in clumps, with a central portion which stains deeply, and in most cases with a thin, strongly refractile capsule which sometimes shows a double contour; but some young forms can be seen which are apparently without a capsule. The size varies from 0·004 millimetre to 0·04 millimetre. Their reproduction appears to be by budding, but I have fancied that I have also seen in a few instances endogenous budding; of this, however, I am not certain. These bodies correspond morphologically with those found in the original tumour and also with those described by Ruffer and myself and by some others of those who have worked at the microscopical appearances of cancer.

EXPERIMENTAL RESULTS.

I have selected from the experimental work which I have done with these organisms those experiments which seemed to me to be the most important. Up to the present time I have not been able to make any such experiments upon such animals as would allow of the easy bringing of these organisms into contact with a likely epithelial surface with the exception of the cornea (*vide* Experiment No. 4), but through the kindness of Dr. Rose Bradford I have been enabled now, at the Brown Institution, to inoculate a bitch in the mammæ, but the time is as yet too short to enable me to make any statement as to the result. The cultures used in the following experiments were made in the medium previously described.

1. *Rabbit.*—Intravenous injection of five cubic centimetres of an eight days old culture. There was no obvious result.

---

[1] A paper read before the Royal Society on March 9th, 1899; communicated by Professor J. Rose Bradford, F.R.S.

[2] Zeitschrift für Hygiene, 189

[3] The following specimens were shown: (1) sections of the cancer from which the cultures were made; (2) the cultures on various media; (3) preparations of the cultures; (4) sections of the organs of the animals in which tumours had been produced; and (5) animals, or portions of them, in which tumours had been produced.

The rabbit was killed 13 weeks afterwards and was found to be apparently normal.

2. *Rabbit.*—Intraperitoneal injection of 10 cubic centimetres of a 21-days old culture. There was no obvious result. The rabbit was killed eight weeks afterwards and was found to be apparently normal.

3 *Rabbit.*—Subcutaneous injection of five cubic centimetres of a three days old culture. There was no obvious result. This rabbit was used later for Experiment No. 4, and when killed 14 weeks after Experiment No. 3 it was found to be normal; nothing was found at the seat of injection.

4. *Rabbit.*—Both cornea were scraped and the sediment of a 10 days old culture rubbed over them. The rabbit was killed in 48 hours. There was considerable proliferation of the corneal epithelium which had forced its way into the subjacent tissue. The organisms were found in the epithelial cells after fixing and staining, with appearances similar to those of the inclusions in cancer cells as described by Ruffer and myself.

5. *Rabbit.*—Trephined and inoculated beneath the dura mater with five cubic centimetres of a seven days old culture. The rabbit died in nine and a half days; the wound had healed. The brain and cord contained the organisms in large numbers. Pure cultures were obtained from the brain, the liver, and the kidney. Nothing was obtained from the blood, the spleen, or the peritoneal fluid.

6. *Rabbit.*—Trephined and inoculated beneath the dura mater with five cubic centimetres of a three days old culture made from the brain of No. 5. The rabbit died in eight days; the wound had healed. Organisms were found in the heart, the blood, the brain, and the cord. Pure cultures were made from the brain, the cord, the kidney, and the liver.

7. *Guinea-pig.*—Subcutaneous injection of five cubic centimetres of a 10 days old culture. There was no obvious result. The guinea-pig was killed in 15 days and was found to be apparently normal; nothing was found at the seat of injection.

8. *Guinea-pig.* — Intraperitoneal injection of 10 cubic centimetres of a three weeks old culture. The guinea-pig died in 20 days. The liver, the lungs, and the peritoneum were studded with new growths of a white colour; the lymphatic glands in the abdomen were enlarged. Pure cultures were made from the liver, the lungs, and the abdominal glands; nothing was obtained from the blood. Sections of the above-mentioned parts showed new growths of an endothelial nature, with the organisms within the cells and free in the tissues.

9. *Guinea-pig.* — Intraperitoneal injection of 10 cubic centimetres of an eight days old culture, made from the abdominal glands of No. 8. The guinea-pig died in 17½ days and showed the same appearances as No. 8. Cultures were made as before and also from the blood. In this case the omentum was also studded with new growths.

I have given here some of the failures and successes which have been constant, and I should like to add that Professor Wright of Netley has repeated some of the experiments I have made and that his results coincide with mine.

The important point, of course, of all this is—the experimental production of malignant tumours in animals by an organism isolated from a malignant tumour in man. That these experimental tumours are, so far with one exception of endothelial origin is due to the fact that until I was enabled to inoculate a dog I found it very difficult to get the organism in contact with likely epithelium; all the above methods of inoculation, save one, could only bring them into contact with endothelial surfaces. No. 4 (the corneal experiment) is the only one in which an epithelial surface was tried and in this case the great proliferation of the epithelium, the appearances of the organisms in the cells, and the irritation produced, were very striking. But the fact of being able to excite a malignant growth with an organism isolated from cancer is, I think, a point of some importance in the etiology of cancer. I am at present experimenting with the view of observing the effects produced by these organisms when brought into contact with epithelia.

The deductions which I think may fairly be made from these observations and experiments are as follows:—

1. That there are certain cancers which occur very rarely in which there are in enormous numbers intracellular bodies of the kind described by Ruffer, by myself, and by others as parasitic protozoa. (From the rarity of these cases and their comparatively acute course one is tempted to think that they are not due to the same cause as ordinary cancers, but there is really no more difference between them and ordinary cancers than between acute and chronic tubercle.)

2. That by the use of appropriate means these intracellular bodies can be isolated and cultivated outside the body.

3. That these cultures when introduced into certain animals can cause death with the production of tumours, so far with one exception of endothelial origin, and that pure cultures can be made from these growths which when inoculated into suitable animals will produce similar tumours.

St. John's Wood-road, N.W.

A CASE OF

TUBAL GESTATION WITH RUPTURE AND FATAL HÆMORRHAGE AT A VERY EARLY PERIOD OF PREGNANCY.

BY F. LUCAS BENHAM, M.D., M.R.C.P. LOND.

THE following case I believe to be sufficiently uncommon to be worthy of record.

The patient was a woman, aged 23 years, who had been married for three and a half months and had never borne a child. She was said to have formerly drunk somewhat to excess and latterly she had suffered from indigestion. Otherwise her health and habits had been generally good. Menstruation had always been regular. Since her marriage (at the end of April, 1898) she had missed two periods—May and June. The July period was profuse, lasted for three weeks, and was followed after an interval of one week by the next period (early in August) which appeared to be normal and which ceased on August 12th, two days before the present illness. On August 14th, 1898, I was asked to see the patient in the temporary absence of Dr. O. A. Crane (who had not previously seen her, however). She was said to be suffering from abdominal pain. I visited her at about 2 P.M. and found her lying in bed. She said that she had not felt well that morning and that on trying to get up she did not feel able to do so. At 10 A.M. severe abdominal pain came on. She admitted having eaten some pork sausages and ice-cream the day before. There was no nausea, vomiting, or diarrhœa. The bowels had been last moved naturally on the previous morning and were regular. The tongue was clean and moist. The skin was very pale and distinctly cool, but the patient had naturally a white or somewhat sallow complexion associated with black hair, so that she had often been supposed by strangers to be Italian. There was, however, no marked pallor of the lips. The pulse was weak and compressible. She was perfectly conscious, not collapsed, could move about readily in bed, and did not seem dangerously ill. I examined the abdomen carefully. There was no distension or abnormal note on percussion and the knees were not drawn up. There was diffused pain over the abdomen, especially over the lower part, and it seemed somewhat greater on the right side than elsewhere; there was slight general tenderness. No tumour was to be felt. The patient confidently denied pregnancy. No vaginal examination was made. The treatment ordered was half an ounce of castor oil to be taken at once, to be followed by one or two draughts containing opium and belladonna. Hot fomentations were to be applied to the abdomen and milk and soda water or arrowroot were to be taken as food. At about 11 P.M. the patient's husband called to tell me that his wife was no better, that the pain was very great, and that she wanted relief and sleep. Two doses of castor oil had been given without any action of the bowels. I went again to the house and found the patient very much worse—in fact, dying. She was extremely pale, with pinched face and staring eyes, and she was gasping for breath. She complained of pain all over the chest and abdomen, that her head was light and swimming, and that she could not get her breath. The skin was cold, except over the abdomen where fomentations had been applied. The abdomen was much distended and dull in the flanks. The patient had passed no urine and had been slightly sick at times. The heart could be felt beating and was rapid, the respiration also was hurried, and the radial pulse was imperceptible. I saw that she could only live half an hour late to do anything, so I merely gave a small hypodermic injection of morphia. Death occurred at midnight.

At the post-mortem examination made 15 hours after death the body was found to be well nourished. The skin was pale, there was not much hypostatic congestion, and there were no lineæ albicantes. Rigor mortis was well marked in all the limbs. Froth issued from the nostrils. The face was pale and bloated. There was a thick layer of subcutaneous fat. On making the usual incisions dark fluid blood ran in a stream from the peritoneal cavity. About three or four pints were sponged up and removed and a good deal of black tenacious clot was taken in fragments from the pelvis, though at present nothing visibly wrong was observed. The heart was healthy but pale. The cavities were empty except for a very little clot in the right ventricle. There was a little emphysema in the lungs and the lower lobes were œdematous; otherwise they were normal. Examination of the abdomen revealed no peritonitis and no tumour or aneurysm could be discovered. The stomach was dilated and it contained several ounces of fluid food. The intestines were normal. The liver was of average size, pale and bloodless, and rather fatty. The spleen and pancreas were normal. The kidneys were of normal size and structure. After removing all the viscera and the remaining adherent blood-clots the uterus and its appendages were carefully examined. A lesion was then observed in the left Fallopian tube. About two inches from the uterus was a small, smooth, elongated swelling about three-quarters of an inch in length and of the size and shape of a small bean; in one spot on its upper surface it was rough, soft, and red, and blood exuded on gentle pressure. This was seen to be the chorion of a very early pregnancy exposed by rupture of the containing Fallopian tube. The ovum seemed partially moveable in the stretched tube and could be rolled about in it. There were no adhesions or any traces of former peritonitis or of any other disease about the Fallopian tube, except one or two very small cysts in the fimbriæ. The uterus was a very little enlarged and was lined by a thin, reddish, adherent membrane (decidua?). The substance of the uterus was normal. Each ovary was enlarged, about two inches in length, and full of cysts as big as peas. In the left ovary was a recent corpus luteum about one-third of an inch in diameter, with a corrugated yellow capsule and a red interior.

Remarks.—The points of interest about the case are as follows:—

1. It is uncommon for extra-uterine gestation to occur in a nullipara as in this case.

2. The chief feature of the case is the early period at which fatal hæmorrhage from rupture of the tube took place. It would be interesting to determine the precise age of the ovum. From the history above given it would appear probable that the woman conceived shortly after marriage and that this ended in an early miscarriage in July. It could not, however, have been this pregnancy, even if no actual abortion had taken place, which led to the final disaster, for an ovum must be still alive and growing to cause rupture of the containing tube and if that had been the case the ovum would have attained a much larger size. Probably another conception took place, dating soon after the catamenia ceased about the end of July or between that and the next menstrual period, which began about August 5th or 6th. At any rate, from the history the duration of the pregnancy at the time of death would appear to be between 10 and 20 days. Mr. T. W. P. Lawrence, the curator of University College Museum, has made a minute examination of the specimen and he reports that from the size of the chorionic vesicle and the development of its villi, which were of considerable length and decidedly branched, the age of the ovum must have been very nearly three weeks, so that conception must have taken place not much later than July 24th, when the protracted menstruation had hardly ceased. Mr. Lawrence's measurement of the distended part of the Fallopian tube is 20 millimetres, the size of the chorionic vesicle from 15 to 20 millimetres. These measurements probably indicate the extreme length and not the diameter of a sphere. But even allowing fully three weeks for the duration of pregnancy, it is very rare (and perhaps unique) for rupture with fatal hæmorrhage to take place as early as this. I have searched through many text-books and voluminous indices but have been unable to find another instance on record. Early rupture is of course not very uncommon but the hæmorrhage is usually slight and only amounts to a hæmatocele and is practically never fatal. I need not quote all the opinions stated in the books about the period at which fatal rupture occurs. I will only mention one or two as examples. Thus Barnes, in his work on Diseases of Women, says that rupture occurs the more early the nearer the gestation sac is to the uterus. Thus an interstitial or tubal gestation usually ruptures from the sixth to the twelfth week though it may be postponed much longer. Six to eight weeks is the time given by most authors. Mr. J. B. Sutton, in his elaborate article on Extra-uterine Gestation in Allbutt and Playfair's "System of Gynæcology," says that primary rupture takes place in the majority of cases between the third week and the tenth week, but he does not say that *fatal* hæmorrhage may take place till after the first month.

3. The most interesting aspect of the case is the clinical one of diagnosis. I think that the difficulties in this case made certainty, when I saw it, out of the question. There was no physical, symptomatic, or historical evidence of pregnancy; the facts were all against it and I therefore excluded the possibility of this being the cause.

The case most nearly resembling mine in this respect that I have found reported is one by Dr. Burton in the Transactions of the Obstetrical Society of London, Feb. 3rd, 1881. In that case fatal hæmorrhage occurred in a woman who was still suckling a child seven months old and who had just menstruated again. The ovum was of the size of a Barcelona nut and was said to be of six weeks' duration. At the time I saw my patient first there was no indication of abundant hæmorrhage, there was no shock or collapse, there was no marked pallor of the lips, and there was no accumulation of blood in the peritoneum. There were, however, two points which I distinctly noticed—viz., coldness of the surface, and a peculiar, weak, compressible pulse. I find that I noted the same phenomena in another case of the kind which I met with several years ago. I suppose they denote hæmorrhage and I might perhaps have attached more importance to these symptoms, but, as I have already said, further evidence of hæmorrhage was wanting. The absence of uterine hæmorrhage was evidence against abortion in case pregnancy existed. I excluded peritonitis, rupture of the stomach, intestinal obstruction, and acute pancreatitis from the diagnosis and was forced to assume, at any rate provisionally, the presence of a bad attack of simple colic. When I saw her at the end the existence of intra-peritoneal hæmorrhage was plain, but she was then dying, and it is doubtful whether transfusion or intravenous injection of saline fluid preparatory to laparotomy would have saved her even if the means of carrying out the process had been at hand, which was certainly not the case.

Elizabeth-street, S.W.

A CASE OF CHEYNE-STOKES RESPIRATION WITH OTHER RHYTHMICAL PHENOMENA.

BY WALTER K. HUNTER, M.D., B.SC. GLASG.,
ASSISTANT PHYSICIAN TO THE ROYAL INFIRMARY AND EXTRA-PHYSICIAN TO THE ROYAL HOSPITAL FOR SICK CHILDREN, GLASGOW.

THE patient in this case, a child aged four years, was admitted to the Glasgow Royal Infirmary on Sept. 19th, 1898, in an unconscious condition, evidently the subject of some form of cerebral meningitis. The history obtained from the parents was to the effect that their child had been quite well till the month of March—i.e., six months before—when she contracted measles, and since when she had been ailing more or less constantly. During the summer the patient was in regular attendance at the outdoor department of the Children's Hospital where I saw her on several occasions and where she was diagnosed as having "some pulmonary trouble, probably tuberculous." Later a persistent diarrhœa set in and it was with difficulty that this could be controlled by means of drugs. A strabismus had been noticeable ever since the attack of measles but not before. The meningeal symptoms were first observed about the beginning of September, commencing with pain in the head and followed later by vomiting, listlessness, and drowsiness. From Sept. 15th the head had been much retracted and coma more or less complete was constantly present. On admission to hospital the child was quite unconscious though the swallowing reflex was still present The pupils were unequal the left being dilated and the right medium Ophthalmoscopic examination revealed a double optic atrophy but no tubercles were to be seen anywhere in the fundus The head was retracted and the abdomen was slightly retracted but was quite soft and doughy to the touch Tache cérébrale was well marked The temperature was 98° F, the pulse was 133 and the respirations were 25 During the first few hours after admission twitching *movements were at intervals noted* in the right arm and leg, also more extensive *movements in* both arms and legs The *respirations all this time were* sighing in character but after midnight the breathing assumed the Cheyne Stokes character the respiratory cycle lasting 50 seconds and consisting of 80 separate respiratory movements The pupils likewise showed rhythmical *movements* *During* the pause they became contracted while with the respiratory movements they began to dilate till at the acme of respiration they were widely dilated While thus dilated the pupils reacted slightly to light Rhythmical movements corresponding in time to the above were also observed in the arms, especially in the right arm The arms it is to be noted were at this time more or less rigid and they presented slight tremor They were extended, with the thumbs adducted and the fingers flexed at the inter phalangeal joints During the advent of the Cheyne Stokes respiration, then, this tremor exhibited a rhythmical activity of such a nature *that during* the pause the tremor was scarcely perceptible increasing however, with the breathing till at the height of the respiratory cycle the tremor presented movements of considerable amplitude As the respiratory movements lessened so did the extent of the tremor movement These various rhythmical phenomena were observed at *frequent* intervals until the time of death, about 30 hours after admission into hospital

On post-mortem examination the convolutions of the brain were found to be much flattened and the soft membranes and ventricles contained a large quantity of *clear serous fluid* Numerous tubercles were to be found scattered throughout the soft membranes The brain substance generally was very soft but otherwise it presented no abnormal appearances Both lungs were studded with miliary tubercles of comparatively large size and there was extensive tuberculous consolidation and excavation of the upper lobe *of the* right lung The right bronchial glands were enlarged and caseous, but the left seemed healthy Miliary *tubercles* were to be seen in the liver, spleen and kidneys and some small and evidently recent tuberculous ulcers were found in the colon and ileum The mesenteric glands *seemed healthy* The medulla and pons were fixed in *formol* and stained with thionin according to Nissl s *method* *Numerous* sections were examined at different levels special attention being paid to the sections passing through the alæ cinereæ In none of the sections, however, could *any distinctive* change be found in the ganglion cells of *either the tenth* the twelfth or of any of the other nerve nuclei *Many* of the ganglion cells I found to be quite normal *Some showed* what has been termed a "polar' or "apical chromatolysis and some were very faintly stained like *to the so called* "ghost cells' But these changes were *seen throughout* the whole medulla and pons not confined *to any special level or* nucleus and I take it that they were due to the meningitis or the *high* temperature (the temperature reached 107 6° before death) and not to be specially *associated with* the Cheyne Stokes respiration

That then very briefly is the record of this case and it would seem to be of some interest in that (1) careful microscopic examination of sections of the medulla through the alæ cinereæ—the supposed rhythmical *respiratory centre*—showed no distinctive change at least not *more than* in the rest of the medulla and pons, and (2) in that *rhythmical* movements were also present in the arms, *showing* the extent of the affection Some time ago Dr Terrien[1] reported a case of Cheyne Stokes respiration where *not only* was there a rhythmical movement of the *pupils* but *also* a rhythmical anæsthesia of the parts of the *face supplied* by the fifth nerve During the pause this anæsthesia was present passing off again as soon as the respiration began In explanation of this Dr Terrien points *out that the* cilio spinal centre and the sensory nucleus of the *fifth nerve* lie close to the respiratory centre and that whatever was causing the Cheyne Stokes breathing had evidently extended its influence to these adjacent centres In my case tactile sense *over the area of the fifth* nerve could not be tested as the child was unconscious all the time the Cheyne Stokes breathing was present But to it Dr Terrien's explanation would not seem to be applicable, for the arm centres are certainly in no way adjacent to those of the pupil and *respiration* My case seems rather to favour the view advanced by Dr G A Gibson[2] that Cheyne Stokes breathing and its accompanying rhythmical phenomena "are instances, among many others of the common tendency towards 'pulsatile or rhythmic activity' manifested by all living *matter'*

Glasgow

THE DIASTOLIC MURMUR OF MITRAL STENOSIS

BY G BURHAM HUNT, M D, M R C P LOND
ASSISTANT TO THE PROFESSOR OF CLINICAL MEDICINE UNIVERSITY COLLEGE HOSPITAL

IT is generally recognised that, as stated by Bristowe[1] the murmur of mitral stenosis may be early, middle, or late diastolic, but the clinical significance of the variation in time of these murmurs is practically unknown, and it was the attempt to discover wherein cases with the early and middle diastolic murmur differed from those with the more ordinary presystolic murmur which led me to examine a series of cases of mitral stenosis From clinical examination of a considerable number of cases I have arrived at the following conclusions in support of which I am unable to give figures, but they will probably be found to agree with the experience of most

1 The murmur in an early compensated case of mitral stenosis, such as is seen in the out patient room and often discovered only on routine examination, is always presystolic Early diastolic murmurs are practically never heard while compensation remains good

2 On the other hand when cardiac failure supervenes and the patient is troubled with dropsy, cyanosis, and other symptoms of mitral stenosis, the murmur is frequently heard in the first half of diastole although even now it is not so common as the presystolic murmur (A long diastolic murmur running right up to the thrust and increasing in loudness and roughness as it approaches the systole is included as a variety of the presystolic murmur)

3 A presystolic murmur may or may not be accompanied by a systolic bruit but an early diastolic murmur is almost always preceded by a systolic murmur A single, early diastolic murmur at the apex is very rare in mitral stenosis and strongly suggests aortic regurgitation even if no murmur is heard at the base

4 A presystolic murmur frequently changes into a diastolic murmur or *vice versâ* in a short time and the period of diastole occupied by the murmur may even vary in the erect and recumbent postures The difference in the cause of these murmurs is therefore not likely to be found in any structural condition of the affected valves, but rather in the way in which the heart is working at different times

I have examined the records of University College Hospital for the past few years in order to see if in the fatal cases of mitral stenosis any post mortem differences could be substantiated between the hearts of those in which during life the murmur was presystolic and those in which it was in the first part of the diastole Such cases are not easy to collect as it is frequently found in mitral stenosis that before death there may be no murmur or it may be confined to the systole so that unless the case is under observation for some time it may be useless for this purpose I have however collected 21 suitable cases of well marked mitral stenosis with necropsies

In 15 cases there was either during life a presystolic murmur or a very long murmur running up to the thrust In 12 of these the left ventricle was either small normal in size or slightly hypertrophied without dilatation, in two the left ventricle was slightly dilated, and in one patient who died, not from the cardiac condition but from septicæmia, it was considerably dilated. In six cases the murmur was in the first part of the diastole and in every one of these the left ventricle was found to be markedly dilated and usually also hypertrophied. So it seems that the early diastolic murmur is heard in those cases of mitral stenosis in which the left ventricle is dilated. Now, in mitral stenosis alone the left ventricle does not dilate; it may either become smaller, as it receives less blood, or it may become slightly hypertrophied, possibly to increase its suction power, as suggested by Giuffré.[2] If with mitral stenosis we find distinct left ventricular dilatation we may be sure, excluding other valvular or visceral disease, that during life there was considerable mitral regurgitation, in which condition dilatation is of course frequent. This great frequency of dilatation of the left ventricle in cases of mitral stenosis with early diastolic murmur, together with the clinical association of such murmurs with systolic bruits, and the fact that this murmur is only heard when compensation is failing, leads to the conclusion that the murmur in the first part of the diastole is only heard in cases of mitral stenosis in which there is free mitral regurgitation. The objection might be raised that with the rigid and useless valves of mitral stenosis there must be very frequently regurgitation and that the early diastolic murmur should be therefore more common. But there are frequently no signs during life or after death that regurgitation has taken place and, as suggested by Samways,[3] this may be due to hypertrophy of the left auricle which, until it gives way, prevents by its more forcible contraction any great mitral regurgitation. The rapid changes in the time of the murmur of stenosis may be due to alterations in tone of the muscle of the left auricle and auriculo-ventricular ring, allowing greater or less regurgitation.

---

[1] Le Progrès Médical Jan 8th 1898

[2] Cheyne-Stokes Respiration (Edinburgh 1892)

[1] Proceedings of the Medical Society of London, 1888 p 41

Although there have been no suggestions as to the significance of the early diastolic as compared with the presystolic murmur, yet there are several explanations as to the mode in which it is produced. There is the view supported by Fagge[4] that it is caused by an increased duration of the auricular systole, so that it drives the blood through the narrowed orifice as soon as the ventricle dilates. Apart from the difficulty of conceiving such a cardiac rhythm on physiological grounds there is the obvious objection that such murmurs are very frequently heard with, but separated from, presystolic murmurs which would be most unlikely if they were both due to the auricular contraction. Balfour[5] ascribes this murmur to the high tension in the pulmonary system forcing blood through the narrow mitral orifice to fill the left ventricle as soon as it is emptied. If this were sufficient by itself to produce a bruit we should expect an early diastolic murmur in all advanced cases of mitral stenosis until the right side gives way, relieving the high pulmonary pressure, whereas such murmurs are only heard in a minority of cases. There is also the attractive theory put forward by Rolleston[6] and adopted by Gibson[7] and others that the early diastolic murmur is due to the negative pressure in the expanding left ventricle sucking blood through the constricted orifice. If the early diastolic murmur is associated with a dilated left ventricle, as appears from my analysis of post-mortem examinations, which unfortunately includes only a small number of cases, it can hardly be explained by this *vis a fronte*. For even if we suppose the wall of the left ventricle to remain of the same thickness and elasticity when the cavity is dilated there would be as a question of physics less negative pressure within it; and as the wall of a dilated ventricle is always softer and less elastic, this loss of negative pressure would be increased. Also, as shown by Roy and Adami,[8] a dilated heart does not thoroughly empty itself and this, again, would diminish its suction-power. So that if, as I have endeavoured to show, cases with early diastolic murmur have a dilated left ventricle the murmur cannot be explained by the negative intra-ventricular pressure, as this would be considerably less in such hearts than in those with a left ventricle of normal size. Another great objection to all these views is that they make no attempt to explain why the murmur should only occasionally be in the early part of the diastole, as such causes would be equally potent in all cases of stenosis. There is, lastly, the explanation put forward by Petit[9] that the diastolic murmur is only heard when the heart is beating slowly, as then the ventricular systole being more complete the left ventricle is better emptied, and there is therefore a more energetic flow of blood into the ventricle at the beginning of diastole, producing a murmur immediately after the second sound. This connexion between the early diastolic murmur and a slow strongly-beating heart is, however, quite disproved, as mentioned before, by clinical examination, the murmur being rather heard with a failing heart.

For these reasons it seems to me that the suggested causes of this murmur in the early half of the diastole are insufficient. If, as I suggest, this early diastolic murmur is always associated with free mitral regurgitation the explanation is simple. The ventricular systole drives a certain quantity of blood back through the constricted orifice into the already over-distended left auricle and pulmonary veins, and at the beginning of diastole these cavities by their elastic recoil drive some of the blood back through the narrowed mitral valve, thus producing the murmur.

This view of the dependence of the early diastolic murmur of mitral stenosis on co-existing regurgitation thus seems to be supported by some clinical and post-mortem evidence; it affords a simple solution of the mechanism of this rather obscure murmur and also explains why it is only heard in a certain number of cases of mitral stenosis.

Gower-street, W.C.

THE ACTION OF THE WATER OF LLANGAMMARCH WELLS ON URIC ACID.

By W. BLACK JONES, M.D., B.S. LOND., D.P.H.,
RESIDENT PHYSICIAN, LLANGAMMARCH WELLS SPA;

AND

EDWARD RUSSELL, B.Sc. LOND., F.C.S., F.I.C.,
SENIOR DEMONSTRATOR OF STATE MEDICINE, KING'S COLLEGE.

THE well-known efficacy of waters containing salts of the alkaline earths in the treatment of lithæmia has induced us to record the following observations on the water of Llangammarch Wells which contains the chlorides of barium and calcium in solution.

A man, aged 66 years, who had suffered for many years from symptoms of renal calculus, consulted one of us (Dr. W. Black Jones) in September, 1896. For the past 10 years he had been taking Contrexéville and Wildungen waters, but without relief. In 1895 he began taking the water of Llangammarch Wells, but in the following year was still suffering from the same symptoms. His urine was acid and the specific gravity was 1020. There was no albumin or sugar present, but he passed a large quantity of uric acid crystals. He suffered from obscure pains in the abdomen and had also well-marked signs of osteo-arthritis in the right knee and in the phalanges of the fingers. In May, 1897, he consulted Dr. Lauder Brunton who reported that all the symptoms of calculus had disappeared. Since then his urine has been free from deposit of uric acid, his rheumatism is much better, and his health is generally improved. He has continued to take a glass of Llangammarch Wells water daily.

The success of the above case induced one of us (Mr. Edward Russell) to make the following series of experiments upon himself. As a preliminary the alkalinity of the following waters was tested with a decinormal solution of hydrochloric acid, 20 cubic centimetres of the water being used in each case. It was found that distilled water was neutralised by 0·1 cubic centimetre of acid, tap water (New River) by 0·8 cubic centimetre, and the Llangammarch Wells water by 0·36 cubic centimetre. The direct action of the above waters on uric acid was then tested in the following manner. 250 cubic centimetres of the water with about one gramme of powdered uric acid were kept at 100° F. in a bath for some hours; 20 cubic centimetres of the solution were then taken, filtered, and treated with standard solution of permanganate of potassium. The results, which are denoted by the amount of solution of permanganate of potassium used, were as follows:—

[9] Charcot's Traité de Médecine, vol. v., p. 250.

Distilled water	2·4	cubic centimetres.	
Tap water	12·3	"	"
Llangammarch Wells water ...	6·6	"	"

The amount of uric acid voided in the urine was estimated as follows: 100 cubic centimetres of urine were mixed with 30 grammes of chloride of ammonium. This solution was allowed to stand for two hours, being frequently stirred, and was then filtered and washed with a saturated solution of sulphate of ammonium; the precipitate was washed off the filter-paper and after adding 20 cubic centimetres of sulphuric acid it was titrated with a standard solution of permanganate of potassium by Hopkins's method.

The experimenter at this time was suffering from obscure pains in the lumbar region and was passing rather less urine than normal, with a heavy deposit of urates. He was drinking about two and a half pints of liquid per diem, chiefly tea and New River water. He was taking a moderate meat diet. After a fortnight's dieting about two and a half pints of urine were passed in 24 hours the specific gravity of which was 1030. The reaction was acid and on analysis there was found to be 0·058 gramme of uric acid per 100 cubic centimetres. A glass of the Llangammarch Wells water was then substituted for the New River water. This was taken twice daily before meals, very little other liquid being taken. This diet was continued for a fortnight. It was then found that three and a quarter pints of urine were passed in 24 hours, the specific gravity of which was 1022, and 0·066 gramme of uric acid was passed per 100 cubic centimetres. After the mineral water had been discontinued for a fortnight two and a quarter pints were passed per diem, the uric acid amounting to 0·09 gramme per 100 cubic centimetres. The results are expressed in the following table.

TABLE I.

Diet.	Amount of urine in cubic centimetres	Increase per cent.	Amount of uric acid in grammes	Increase per cent.
1. Normal	1410	—	0·83	—
2. Mineral water	1900	31	1·25	50
3. Normal	1300	—	1·18	42

In each of the above cases the results represent a mean of two analyses.

A second series of experiments was then conducted, the urine being analysed while a normal diet was being taken and again after a mineral water diet of six days' duration. The results were as follows:—

TABLE II.

Diet.	Amount of urine in cubic centimetres.	Increase per cent.	Amount of uric acid in grammes	Increase per cent.
1. Normal	1130	—	1·03	—
2. Mineral water	1530	35	1·34	30

We conclude from the above observations that the effect of substituting the Llangammarch Wells water for ordinary water is to increase the quantity of urine passed and also to increase the output of uric acid. This increase of the latter is also maintained to a certain extent when the water is no longer taken, but gradually returns to the normal for that individual.

The relation of uric acid to the various manifestations of gout and its deposition in the kidney in the form of calculus has been studied during recent years by several eminent members of the medical profession who have contributed much to our information on the subject. Considerable advances have been made in our knowledge as to its circulation in the blood and the factors determining its deposition in the tissues. The influences affecting its elimination from the body are, however, less well known to us. Many attempts have been made to discover a solvent of uric acid, but these experiments have not as yet been successful. Several mineral waters have long enjoyed a repute in the treatment of this diathesis, but most of them do not act as solvents at all, their action being chiefly diuretic. Some of the well-known waters would even seem to be contra-indicated on chemical grounds, although clinically the results are good. According to an analysis of Contrexéville water, for example, sulphate of calcium is the only mineral ingredient occurring in any important quantity in this water.

In the above experiments it will be noticed that chemically tap water is a better solvent of uric acid than Llangammarch Wells water, yet when the latter was substituted for the former clinically there was an increase of the output of from 30 to 50 per cent. It will be observed that the increased diuresis was due to the action of the mineral water alone, as the same quantity of liquids was taken in each case. The action of the Llangammarch Wells water in eliminating uric acid has thus an important bearing on the treatment of chronic gout and allied diseases. The following evidence gives the results of its employment in such cases. A number of patients visit Llangammarch annually suffering from gouty swellings of the joints. After a course of mineral water in nearly every case there is considerable benefit, the swellings decrease, there is less pain, and there is less stiffness in the joint. In many cases baths of the mineral water and also massage are used with very good results. In a few instances which at first appeared most unpromising considerable relief has been obtained. In the same manner there has been success in the treatment of osteo-arthritis. We therefore consider that in the Llangammarch Wells water we have a valuable adjunct to the present treatment of the uric acid diathesis, that substance being eliminated in considerable amount, hence this water is indicated in cases of gout, osteo-arthritis, uric acid, gravel, and calculus. In addition to the mineral water treatment there are at Llangammarch the advantages of a spa within a few hours' journey from London, together with a mountain atmosphere and such various forms of exercise as walking, hill-climbing, golf, &c., which are invaluable aids to the balneologist.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON DIAPHRAGMATIC PLEURISY.

By GEORGE A. CLARKSON, F.R.C.S. Eng.

THE subject of diaphragmatic pleurisy is of exceptional interest to the surgeon on account of the symptoms being so very suggestive of some grave abdominal affection. The differential diagnosis is generally far from easy, for few signs, if any, are discoverable on the most careful examination and in the majority of cases no effusion follows. The most striking symptom is severe pain in the upper part of the abdomen. The diaphragm is fixed and the abdominal walls consequently do not move on respiration. The respiration is quickened and expansion is confined to the upper part of the thorax. There is generally some accompanying fever. Coupled with these symptoms is one of the most marked features in the disease, an extremely anxious countenance. The expression is such as one is accustomed to see in bad abdominal lesions. Some cases of pneumonia present this train of symptoms at the onset and I suppose that there can be no doubt that this is due to the presence of diaphragmatic pleurisy. The following case which came under my care illustrates in a striking manner most of these points.

Late one evening I was asked to see a boy, aged 11 years, whose mother gave me the following history. He had been perfectly well in the middle of the day when he came home to dinner and partook of a good meal. He then went out to play with some other boys and returned home ill and evidently in great pain. When I examined him there were no bruises or any signs whatever of injury on the body and no broken ribs. He complained of acute pain in the abdomen and lay on his back with his knees drawn up. The abdomen was somewhat distended, motionless, and very rigid. It was tender on pressure, but the tenderness was general and not localised to any one part. The breathing was moderately rapid, the upper part of the chest only being used. Nothing abnormal could be detected in the chest. The temperature was 102° F. and the pulse was 125 per minute. The boy's general aspect was one of pain and anxiety. As I was by no means clear in my mind as to the cause of these symptoms I awaited further developments. The following morning the boy was about the same but the abdominal symptoms were not so marked. There was less rigidity of the abdominal muscles and the knees were at times extended. The temperature was higher (103°) and the breathing was more rapid. In the evening fine crepitations could be heard at the base of the right lung and the case ran the usual course of one of lobar pneumonia. On the third day after the onset the abdominal symptoms had quite disappeared. The patient made an uneventful recovery.

I have had the opportunity of seeing a similar case of an adult exhibiting the same apparently acute abdominal symptoms which gradually gave way as the physical signs of pneumonia manifested themselves.

Leicester.

SARCOMA OF THE FEMUR.

BY FRANK A. ARNOLD, M.B. LOND.

THE following notes of a case of sarcoma of the femur may interest those who study the pathology of disease in people other than Europeans.

A young adult native was admitted into the Memorial Hospital, Bulawayo, on Oct. 15th, 1898, suffering from a large swelling over the lower third of the left femur. He stated that he first noticed that his thigh was swollen at Christmas, 1897, and that the swelling had since steadily increased. On admission a large tense tumour was found over the lower third of the femur, attached to both the bone and the skin. There was no fluctuation. The skin was broken for an area of about the size of a half-crown and the wound so formed was very foul. The swelling was about six inches across at its widest diameter and was fairly well defined and rounded. It was very painful but not tender to the touch. The veins of the skin over the swelling were not much enlarged. The glands of the groin were not more enlarged than would be accounted for by the skin wound. The "boy" had been picked up on the veldt and was weak although not emaciated. Examination showed no affection of any other part of his body. Amputation at the upper third was at once performed. Three days later the patient complained of pain in the right lung and he had a cough and slight hæmoptysis. Examination revealed crepitations all over the front of the right chest but no appreciable dulness. The pain was very great. The chest symptoms became more marked and in about 10 days definite dulness over the lower lobe of the right lung could be made out and from this time onward the signs of lung affection became more and more marked. The superficial veins of the body became enlarged and the face and neck, especially on the right side, became œdematous. There was no ascites. The patient died on Feb. 12th, 1899.

Examination of the amputated thigh showed that the growth had started inside the shaft of the bone at its junction with the condyles and had eaten through the anterior surface of the femur, splitting off the internal condyle from the rest of the bone. Hæmorrhage had taken place into the centre of the growth which was well defined except at the junction with the bone and the point where the overlying and adherent skin had given way. The post-mortem examination showed that the bases of both lungs and the mediastinal glands were occupied by a firm white secondary deposit. Elsewhere both lungs were studded with white isolated patches, some rounded and dimpled and others large, irregular, and undergoing cystic degeneration. Only small areas of healthy lung tissue were to be found in either lung. All the other organs of the body were healthy as was also the bone with the marrow of the stump. Microscopical examination showed the original growth in the femur to be a myeloid sarcoma and the secondary growth a spindle-celled sarcoma.

The point of interest in this case is that it shows that a malignant growth in a native may be identical in its origin, progress, and structure with a similar growth in Europeans. The "boy" was assumed to belong to the Zulu tribe. Although his skin was somewhat lighter in colour than is usual I do not think that either of his parents was a European. It is possible that there was a strain of European blood in the patient but if so it must have occurred two or three generations back.

Memorial Hospital, Bulawayo, South Africa.

ST. MARY'S HOSPITAL.

A CASE OF PERFORATION OF GASTRIC ULCER; OPERATION; RECOVERY.

(Under the care of Dr. SIDNEY PHILLIPS and Mr. A. QUARRY SILCOCK.)

THE following case presents several features of interest. In the first place, 33 hours elapsed from the time at which the perforation occurred to the time of operation and yet the patient recovered, and this successful result cannot be attributed to the absence of the gastric contents for only an hour previously to the perforation she had partaken of a meal and peptonised milk was given even later. The fortunate issue must be ascribable in part to the smallness of the aperture of perforation and the rapid formation of peritoneal adhesions. We have on several recent occasions pointed out the rarity of a successful result in perforation of the stomach when more than 24 hours have elapsed between the perforation and the operation. This case also illustrates the great value of a gauze drain, for its presence rendered harmless the failure of the first attempt at closure of the perforation. The occurrence of parotitis in abdominal cases is always of interest and Mr. Silcock's suggestion as to the cause of this complication is very ingenious and may serve to explain many at least of the cases, if not all. We consider his recommendations as to the prophylactic treatment to be well worthy of trial.

A girl, aged 20 years, had in September, 1896, an attack of pain in the upper part of the abdomen with vomiting and kept her bed a week; since then she had been subject about every three months to attacks of the same character but of less severity and without vomiting. Between the attacks she had been free from pain and had not restricted her diet in any way. She had an attack in February, 1898, and one in May of the same year. There had never been any hæmatemesis. The attacks were regarded as hysterical. She was unusually well during August and until Sept. 14th, 1898; on the 13th she ate a raw apple as she had frequently done before and had no discomfort after it. On the 14th she ate breakfast as usual and at 11 A.M. she took some cocoa and bread and butter; one hour later she experienced severe pain in the upper part of the abdomen and lay down on the floor. Soon afterwards she vomited. Dr. A. B. Rendel, who saw her in the afternoon, found her somewhat collapsed, and he had a bed made up for her in the room where she was taken ill. She had peptonised milk and ice to take. The evening temperature was 100° F.; during the night there was pain in the abdomen and shoulders and she vomited twice. She was sent to St. Mary's Hospital on the 15th at 5 P.M. Dr. Phillips saw her at 7 P.M. She was a well-nourished, healthy-looking girl. The face was flushed, there were slight dark areolæ under the eyes, the features were a little pinched, the tongue was clean, abdominal movements were a little restrained, and there was hyperæsthesia over the whole abdominal surface. She complained of pain in the right iliac fossa, but there were no dulness on percussion, no tumour, and no tenderness in this region; there was, however, acute tenderness over an area of about two square inches immediately to the left of the linea alba just above the level of the umbilicus; here there was more resistance than elsewhere and slight defect in percussion resonance. Liver dulness could be mapped out in the margin of the thorax. No stomach note could be obtained except in the region of the left axillary line; there was no bell sound obtainable. The pulse was 120, very sudden and jerky, and the temperature was 100·2°. She had vomited just before admission.

Remarks by Dr. SIDNEY PHILLIPS.—The sudden acute abdominal pain, collapse, and vomiting, with subsequent pyrexia, pointed to a perforation of some part of the alimentary canal. The pain was felt in the iliac fossa, but pain is of little value as a localising symptom in acute abdominal disease, and in the absence of tenderness, tumour, percussion dulness, or undue resistance in the right iliac region appendicitis was negatived. The local tenderness and the tension of the left rectus muscle suggested that the lesion was in the situation of the stomach and the symptoms pointed so strongly to a perforation that the pre-existence of an ulcer of the stomach seemed certain though the history of paroxysmal attacks of pain with intermissions of many weeks was unlike the course of ulcer as generally described; the intensity and localisation of the tenderness pointed to its being on the anterior surface. There was no encroachment on the liver dulness and a stomach note could be obtained in the axillary line; the stomach therefore was not entirely empty of gas nor was there any evidence of widespread escape of gas into the peritoneal cavity. Perforation of the stomach may, no doubt, be recovered from, but that is most likely when the stomach is empty or where there are previous adhesions; in this case the stomach contained liquid at the time of the perforation and afterwards. The fever, the quick pulse, and the flush of the patient's face made the presence of peritonitis certain and the general condition would, I felt sure, rapidly become worse. I therefore sent at once to ask my colleague, Mr. Silcock, to operate and after a little delay in obtaining the consent of the mother the girl was brought into the operating theatre at 9 P.M. I noticed immediately before the operation that the physical signs had somewhat changed and that there was hyper-resonance over part of the right hypochondrium. The notes were taken by Mr. W. Ferris, my clinical clerk.

Operation.—At 9 P.M., ether being administered, an incision two and a half inches long was made by Mr. Silcock a little below the xiphoid cartilage in the linea alba; the structures of the abdominal wall were divided, the subcutaneous fat being thick. Recent adhesions of lymph were found in all directions on opening the peritoneum. The wound was now lengthened and a horizontal cut was made to the left side for one and a half inches. A good deal of serum escaped, and upon examination a small perforation was found a little to the left of the linea alba in the lower part of the anterior wall of the stomach, through which escaped a small quantity of frothy mucus. The surrounding peritoneum was covered with soft adhesive lymph. After cleansing the wound several unsuccessful attempts were made to close the perforation by invaginating its edges and stitching with Lembert's sutures, failure being due partly to the difficulty of passing sutures at the bottom of a deep wound with the left lobe of the liver overhanging the perforation, and partly to the stitches cutting through the softened tissues. However, by the aid of long rectangular cleft palate needles and silk sutures this was ultimately effected. The wound was washed out with sterilised water, the greater part of the vertical parietal incision was closed with silkworm gut sutures, and a large double cyanide gauze drain and dressing were applied. The operation lasted one and a half hours. The patient passed a quiet night; there was not much pain and no sickness. On the 16th the temperature at 10 A.M. rose to 101°. Enemata of three ounces of peptonised milk or beef tea with brandy were given every four hours. The wound was dressed in the afternoon and brown biliary fluid was found on the dressings. Soon afterwards a greenish fluid was vomited, with escape of thick green acid fluid from the wound. On the 17th she was better: the temperature was from 100° to 102°. There was a copious greenish discharge; the sutures had evidently given way, and by the aid of an electric lamp the perforation could be seen at the bottom of the wound. On the 18th the maximum temperature was 101°. The wound was irrigated with boric acid lotion and plugged with cyanide gauze wrung out in a solution of bicarbonate of soda. On the 19th there was acute pain with tenderness and swelling of the left parotid gland, the temperature rising to 102°. Belladonna fomentations were applied, and acid drops were ordered to be sucked to stimulate the flow of saliva; the nutrient enemata were well retained. She had one-eighth of a grain of acetate of morphia, but did not sleep well. On the 20th the parotitis was less acute. Relief was afforded by the application of dry heat by means of a Japanese muff warmer. The temperature was from 101·6° to 102°. A bile-stained discharge was still present. On the 21st the maximum temperature was 101°. The discharge was offensive. Iodoform gauze plugging was substituted for the cyanide. On the 22nd the temperature was 100·4°. There was dulness with some tenderness in the left hypochondrium, and Mr. Silcock passed a long probe from the wound towards the left into a cavity from which the offensive discharge could be seen to flow, and decided to at once make a counter opening. Under an anæsthetic the wound was well irrigated. A counter-opening by a horizontal incision one and a half inches long was made in the eighth left costal space: a large drainage tube was then passed from one wound to the other and the cavity was again irrigated. The little finger inserted through the perforation detected no signs of ulceration of the surrounding mucous membrane. With some difficulty the edges of the perforation were invaginated and approximated by three Lembert's sutures. The sutures were deeply passed and must have included nearly the whole thickness of the gastric wall. The wound was plugged lightly with cyanide gauze and a dressing was applied. The patient recovered from the anæsthetic without sickness. The temperature rose to 104° in the afternoon and fell to 102° by night. The wound was dressed at night; it was less offensive and there was no discharge from the stomach. On the 23rd the maximum temperature was 100 6°. The discharge was still offensive, but none came from the stomach. All parts of the wound were covered with healthy granulations. On the 24th she took food by the mouth for the first time, three drachms of sweetened barley water being allowed every two hours. There was no leakage from the stomach. From this time forward the patient made an uninterrupted recovery. On Nov. 21st she got up, the wounds being practically closed, and was discharged to a convalescent home on Dec. 14th.

Remarks by Mr. SILCOCK.—We are much indebted to Dr. W. C. Wood, house surgeon, for the careful surgical notes of the case. The failure to effect permanent closure of the perforation at the first operation and the success attending the second show how unnecessary it is, as often has been insisted, to do more than provide for the exit of the extravasated stomach contents from the peritoneal cavity, where that is possible, in cases in which the complete operation would from its complexity or long duration endanger life. The occurrence of parotitis in abdominal cases is not infrequent. May it not be due to the fact that such patients often enough suffer from stomatitis, for but little food is taken and that fluid in kind, or possibly none may be allowed, as in our case: the mucous membrane thus becomes fouled, there is no stimulus to the flow of saliva, consequently infective organisms may find their way up the parotid or other salivary duct, the current of fluid in which may be materially lessened in force and volume. *Hence it is well to see that* the mouth and teeth are cleansed, and possibly it may be a *good thing* to allow the patient to stimulate the flow of saliva by some such means as that adopted in our case. The patient reported herself in January, 1899, as perfectly well.

WEST OF ENGLAND EYE INFIRMARY, EXETER.—The foundation-stone of the new building of this institution will be laid by Mr. George Franklin, J.P., on April 11th. Up to the present £7541 have been received towards the building fund, but further donations are much needed.

LITERARY INTELLIGENCE.—Messrs. Williams and Norgate's book circular for March includes the following recent publications:—"Untersuchungen über Strukturen, insbesondere über nichtzellige Erzeugnisse des Organismus," by O. Butschli; "Grundriss einer Geschichte der Naturwissenschaften," vol. ii., by F. Dannemann; "Die Masken und Geheimbünde Afrikas," by L. Frobenius; "Geschichte der Wiener Universität von 1848-98"; "Technisches Wörterbuch in Vier Sprachen" (English, Italian, German, French), by E. Webber; "Leçons de Clinique Surgicale," by P. Delbet; "Handbuch der Toxikologie," by Professor A. J. Kunkel; "Lehrbuch der Speziellen Chirurgie," by H. Tillmann; and "Das Becken mit [illegible] Beri[illegible]igung der Chirurgie und Gynakologie," [illegible] W. [illegible]er.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Experiments on the Toxicity of Urine.—Epithelial Tumours of the Eyebrow.—Diffuse Syphilitic Change in the Liver.—Exhibition of Specimens.

A MEETING of this society was held on March 21st, Dr. CHARLEWOOD TURNER, Vice-President, being in the chair.

Dr. HERRINGHAM gave an account of a series of Experiments upon the Toxicity of Urine. He recalled the fact that since disease of the kidneys had been known to be a cause of death this effect and the general group of symptoms to which the name "uræmia" was given had been till recent years universally, and were still commonly, believed to be due to the retention of waste products. Recently uræmia had been explained by the loss or perversion of an internal secretion, but the evidence for this was as yet insufficient. No definite poisonous constituent of the urine had been demonstrated in uræmia. Urea, uric acid, and all the known organic bodies which the urine contained had been injected into the circulation in excessive quantities without producing the symptoms. In default of any satisfactory explanation by these means pathologists had been driven to other theories—first, that of cerebral œdema championed by Traube; secondly, theories which ascribed uræmia, not to a constituent of the natural urine, but either to a body produced by decomposition of the retained urine within the body, such as Frerich's ammonium carbonate, or more recently to a precursor of urea, such as the salts of carbamic acid, which were put forward by Nencki and others on experimental evidence. Fresh light was thrown on the subject by the experiments of Feltz and Ritter in France and Astachewsky in Russia who in 1881 injected considerable quantities of urine itself into the circulation in dogs. They ascribed the fatal effects of these injections chiefly, or even entirely, to the potash salts. Their experiments were repeated by Bouchard of Paris who denied the sufficiency of the potash salts on several grounds, ascribed a partial toxicity by a kind of division of labour to all the constituents of the urine, and supposed that seven different poisons existed in the urine, each productive of a special symptom. Bouchard further found the urine of sleep less toxic than that of day and more convulsant in its effect and was led to form a theory of sleep, according to which men by day secreted a body possessed of narcotic properties which by its accumulation induced sleep, while during sleep this gave place to another substance of a convulsant nature which by inducing muscular movements led to waking. Dr. Herringham had been engaged during the last three years in repeating these experiments and during the same time Beck in Germany had been similarly occupied. Their conclusions so far as their work had overlapped were similar. Bouchard's statements rested upon no chemical analysis, but upon physiological symptoms alone. He had produced not one of the bodies whose presence he asserted, and had not even observed the presence or variation of those bodies known to exist in the urine. For instance, while denying the sufficiency of potash salts he gave no quantitative analysis of the amount contained in the urines injected. Furthermore, in many respects neither Beck nor Dr. Herringham were able to confirm his account. The urine of sleep, for instance, was not in their experience more convulsant than that of day. Thirdly, the variation of rabbits, which were the animals upon which Bouchard experimented, was so great that the differences upon which Bouchard relied were within the error thus caused. Dr. Herringham had endeavoured carefully to observe the symptoms induced in rabbits by these injections and then to compare by quantitative analysis the variation of different constituents of the urine. By this means he reached the conclusion that none of the constituent bodies but potash varied with the toxicity of the urine, and after making a necessary modification of the classical method of potash analysis in urine he was able to show so close a parallel between these two that he had no doubt that potash was the only cause of the fatal result. In every instance there was sufficient, and in nearly all much more than sufficient, potash to produce death. The lesser toxicity of the urine of sheep was simply owing to a lesser excretion of potash. Diagrams were exhibited to show the relation of various other urinary constituents and of potash and also illustrated the extent of variation in rabbits as evidenced by cases in which a pair of rabbits had been treated with the same sample of urine. The difference between the two animals was never less than 6 per cent. and ran up to 52 per cent. The symptoms of animals thus injected were myosis, drowsiness, lowering of blood-pressure from cardiac failure, retardation and embarrassment of respiration, loss of body heat, and finally fatal convulsions. The resemblance of these to uræmia was evident but no conclusion could be drawn thence until clinical investigation had followed up the suggestions of experiment. Since the degree of the urinary toxicity was merely an inexact way of stating the amount of potash salts, injection experiments on animals could not take the place of quantitative chemical analysis. Bouchard had laid down a standard of excretion for the normal man, but Dr. Herringham had found the normal to vary under ordinary conditions (and much more under conditions of light diet and rest in bed) too greatly to admit of any useful comparison in disease unless by a long series of observations on each patient. Isolated estimations were quite valueless. Lastly, Bouchard had rested his theory of auto-intoxication in general largely upon the conclusions derived from urinary toxicity. Auto-intoxication was a word of confused meaning, comprising, firstly, cases of perversion or loss of the internal secretion of a gland; secondly, cases of perverted metabolism during primary or intestinal digestion, with absorption of the abnormal products; and, thirdly, similar processes occurring during the hepatic or even during later stages of assimilation. The only proved instance of the first class was that of the thyroid; the second and third were purely hypothetical. Urinary toxicity being due to potash salts could not lend support to the use of the term auto-intoxication under any of these three meanings.—Dr. CHARLEWOOD TURNER observed that in uræmia there was not merely retention of substances, but a condition in which the secreting substance of the kidney was altered, and the production of urinary ingredients was interfered with so that the natural secretion failed to be performed. The conditions in experimental injection of urine into the veins of animals were not the same as those in the production of uræmia, as the blood received the poisons suddenly instead of gradually. He still thought that the symptoms of obstruction did not quite correspond with those of suppression. So far as the cause of the toxicity of urine injected into animals was concerned Dr. Herringham's experiments appeared to be decisive.—Dr. ROSE BRADFORD confirmed the description given of the train of symptoms which followed the injection of urine into the circulation of animals. If Bouchard's theory were correct the urine in uræmia should have lost its toxicity, but this was not the case. Dr. Bradford did not think that there was any one cause for uræmia, as it was not due to the retention of any one constituent of the urine. No one had succeeded experimentally in producing uræmia by excising the kidneys or ligaturing the ureter, these producing the condition described by Sir William Roberts under the term "obstructive suppression," symptoms which he could not agree with Dr. Herringham in regarding as the same as those of uræmia due to structural disease of the kidney. He mentioned a case which he published in which there was necrosis of the cortex of both kidneys in which the patient lived a week, passing only about two drachms of urine, but there was clearness of mind up to the end, the symptoms being those of calculous suppression.—Dr. HERRINGHAM, in reply, said that he had been careful to avoid suggesting that the conditions in man were the same as those in the rabbit. He had not intended to infer that uræmia in man was due to retention of potash salts, but he thought that he had proved that the presence of potash salts was the cause of the toxicity of the urine when injected into the veins of an animal.

Dr. RADCLIFFE CROCKER read the account of a case of Multiple Tumours arranged in a Vertical Band from the right eyebrow to the hair margin in a girl aged 10 years. They had been developing six years, apparently as the result of a slight injury. They were convex, pale red, and varied in size from that of a hempseed to that of a half of a damson and gave no inconvenience. Structurally the growth was deep in the corium, composed of small epithelial cells in lobules separated by fibrous septa, with the appearance of a rodent ulcer. Their development could be distinctly traced from several ducts and hair follicles. The sebaceous glands were absent or rudimentary and could not be proved to take any part in the tumours, as there were no intermediate stages. Dr. Crocker suggested that the tumours were derived from the embryonically defective appendages of the skin and probably were excited by a blow on the forehead —Mr. RAYMOND JOHNSON showed sections from a similar specimen removed from the shoulder of an adult woman, where it formed a flat elevation. It was covered by epidermis. It consisted of masses of epithelial growth closely resembling the appearances in rodent ulcers. He also referred to a similar specimen removed from the buttock.

Dr. F. PARKES WEBER showed Sections from the Liver of a man, aged 47 years, the subject of advanced tertiary syphilitic disease of the testes, &c, who died from cerebral hæmorrhage The liver was somewhat enlarged (the weight was 67 ounces) and, though it showed no distinct gummata or scars resulting from gummata, presented a diffuse, more or less generalised fibroid change Microscopic sections showed that this change might be regarded as the result of a "peri cellular" or "peri capillary' cirrhotic process such as had been more frequently recorded in connexion with congenital syphilis than with the acquired disease What Dr Weber specially drew attention to was a tendency in the present instance and in some analogous cases for the fibrous change to be most advanced in the central portions of the acini and least noticeable around the portal spaces The best preserved glandular cells were those at the periphery of the acini, precisely those which were most likely to be encroached upon in ordinary cirrhosis. The fact that the inner and middle zones of the acini were the most affected, just as they were in chronic passive congestion and amyloid disease (which latter was absent in the present case) respectively, suggested that the harmful process in diffuse syphilitic disease of the liver was connected rather with the minute branches of the hepatic artery than with those of the portal vein. An analogy might be drawn between the change pointed out by Dr. Weber in the liver and the change observed in some cases of "cardio-sclerosis" when the portions of the myocardium farthest removed from the arterioles were chiefly affected by the fibroid degeneration

The following card specimens were exhibited:—

Dr NORMAN DALTON. Two cases of Involvement of the Recurrent Laryngeal Nerve (1) by an Ulcer of the Trachea, and (2) by Calcareous Mediastinal Glands

Dr. CAMPBELL THOMSON: Secondary Growths of Melanotic Sarcoma in the Small Intestine

Dr. PARKES WEBER Lipoma of the Kidney

Mr. CECIL BEADLES: (1) Spontaneous Rupture of the Heart; and (2) Hæmorrhage into the Suprarenal Body

Dr. H D ROLLESTON: Exulceratio Simplex of the Stomach.

HARVEIAN SOCIETY OF LONDON.

Modern Views on Gout

A MEETING of this society was held on March 16th, Mr HENRY JULER, President, being in the chair

Dr MOUILLOT read a paper on Modern Views on Gout in Relation to Treatment. He commenced by defining gout as a disease in which uric acid in the form of a quadriurate was present in the blood in recognisable quantities and in which this uric acid was deposited from the blood into the tissues as sodium biurate This latter compound was only soluble in serum to the extent of one part in 10 000 and in distilled water at blood heat to the extent of one part in 1000 The formation of uric acid was then discussed at some length, preference being given to the view that it was produced in the liver. It was a clinical fact that excess of animal food and alcohol directly tended to gout Wines so noted because of their injurious effect on the liver and not on account of their acidity. When excess of animal food and wine went together the greatest injury was done to the metabolic activity of the liver, and the prevalence of acute gout in former times was due to this excess The symptoms of acute gout needed no description, but in chronic and irregular gout there was much difference of opinion among medical men with respect to the class of patients they called gouty, particularly in the differentiation of gout from rheumatism Dr Mouillot's opinion was that gout was a common disease but that rheumatism was rare He did not say that there was no such thing as rheumatism apart from rheumatic fever, but cases of rheumatic arthritis became fewer as one gained experience With respect to treatment, colchicum was the drug *par excellence*, because it acted as a powerful stimulant to the liver and intestinal glands, improving the metabolism in the liver and removing by the bowels some of the antecedents of uric acid Mercury was undoubtedly also called for in most cases of acute gout Dr. Mouillot had found salicylate of soda unsatisfactory and would probably never use it again. The chief dietetic faults of the gouty were eating too much and drinking too much and also drinking too little This last fault was a very serious one and was specially noticeable in women and teetotalers Women had been so often told that in order to retain their figures they must not drink at meals that many approaching middle life drank far too little fluid. The tendency to stoutness which caused women to restrict their allowance of fluid, coming on as it usually did about the same time as the menopause, was a factor which, added to the cessation of the menses, accounted for the great number of mildly gouty women from 45 to 50 years of age. One good meat meal was generally sufficient with vegetables in moderation, whilst at another meal a little fish, with vegetables and fruit in quantity, might be taken In very bad cases the different types of food should not be habitually taken at the same meal Wines were best avoided Vegetarian diet was neither necessary nor desirable except in the rare cases where patients were unable to digest meat Plain water, Salutaris, Vichy, or Apollinaris should be drunk at 11 A M. and at bedtime. Too little fluid was a common cause of ill health A moderate amount of exercise should be taken daily, but excessive muscular exertion should be avoided Turkish and other baths should be used regularly. Dr. Luff's work showed the futility of trying to dissolve sodium biurate by alkalies, but at the same time alkalies did have in some cases a beneficial effect on digestion and metabolism, so that if thought desirable lithia or some other alkali could be added to the water that was taken No reference was made to foreign spas, but Dr. Mouillot said that at the British ones, such as Harrogate, Bath, Buxton, or Strathpeffer, one could not go wrong by placing a patient under the care of a judicious local practitioner who ought to be left in full control of the case. He by no means agreed with Sir William Roberts in condemning waters which contained sodium salts There was a great similarity between the action of strong sulphur saline waters and that of colchicum They were both cholagogues and both diminished the output of uric acid Their beneficial effect on gout was in both cases due to their stimulating influence on the liver and intestinal glands Dr. Luff claimed for colchicum an indirect solvent effect on uric acid, as by diminishing its amount in the blood it enabled that fluid to take up some which had been deposited in the tissues, and Dr. Mouillot made the same claim for the Harrogate waters on exactly the same grounds

Dr BEZLY THORNE said that it had been a pleasure to him to listen to an exposition of views so largely in accordance with his own, while he explained that his own were founded upon personal experience

Dr A P LUFF urged the importance of avoiding the use of salicylate acid or sodium salicylate in the treatment of gout since it was not only useless but in many cases he had found it do positive harm He entirely supported Dr. Mouillot's statement that many gouty people drank too little and especially had he found this to be the case with female gouty patients in whom the total amount of daily fluid consumed would frequently average not more than from 18 to 20 ounces He thought that his investigations on the influence of alkalies on the solubility of gouty deposits had been misunderstood by many medical men He had never advocated the abandonment of alkalies in the treatment of gout. What he had shown was that alkalies and their congeners were useless when administered with the object of dissolving gouty deposits, but he (Dr Luff) frequently employed alkalies in the treatment of gouty dyspepsia and of gouty affections of the liver

Mr WILLIAM ARMSTRONG, while agreeing with Dr. Mouillot that gout was more frequently met with than rheumatism, thought that there was just now rather a tendency to consider all articular and muscular pains gouty and to under estimate the rheumatic element which was often of considerable importance from the point of view both of therapeutics and of dietetics Dr Luff's valuable work had shown that in cases of persistent gout and goutiness there was almost constant failure to excrete the normal amount of uric acid and he (Mr Armstrong) had been greatly aided in the diagnosis of doubtful cases by the estimation of the 24 hours urine by the Gowland-Hopkins method. With regard to dietary as a general rule a certain amount of butcher's meat was necessary; in a considerable number of cases on a non-meat diet he had observed that although the actual amount of uric acid formed got less the rate of excretion diminished to a still greater degree. Beef and mutton certainly stimulated the process of excretion. In nearly 100 cases dieted exclusively on minced beef and hot water there was at first an enormous increase in the quantity of uric acid excreted, which the advocates of a non-meat dietary would say was conveyed into the system by the beef; but as the gouty troubles improved the excretion gradually fell to normal, although there was no change in the diet. In giving red meat to the gouty it was necessary to cut down as far as possible the consumption of carbohydrates and of milk and also to insist upon the drinking of hot water one hour before each meal. Fresh vegetables were of the greatest value, but they should be well cooked and should be freed from crude and indigestible matter. A separate vegetable course at dinner was most useful. Certain gouty cases could be treated with an equal amount of success either on the lines suggested or by the dietary advocated by Dr. Alexander Haig, consisting mainly of carbohydrates, milk, and fruit; but it was of the first importance that the two classes of food should not be mixed as in that direction lay certain disaster for the gouty. Modern researches concerning gout seemed to resolve its treatment into two portions: (1) the prevention of the formation of the antecedents of uric acid by attention to the condition of both gastric and duodenal digestions and to the action of the liver—that much abused organ which was so frequently the victim rather than the culprit; and (2) the stimulation of excretion by attention to the functions of the kidneys, skin, bowels, and nervous system. To a lowered condition of the last named much of the modern irregular gout was due.

Dr. Mouillot, in reply, said that he was much interested in Dr. Bezly Thorne's experience. It bore out his view that the initial difficulty in gout was a digestive one and that the gouty were unable to digest the various classes of food at the same meal. The rigidity of the diet rules must be in proportion to the severity of the symptoms, as a sacrifice which it might be worth while making in a severe case might not be so in a mild one. He said that his view was that the true cause of gout was digestive and that the uratic deposits which were responsible for most of the symptoms were due to subsequent failure of the kidneys either as a coincidence or caused by the toxic poisoning due to the uric acid or perhaps some other poison. Dr. Mouillot was quite sure that Mr. Armstrong's practice of calling in the aid of the skin to assist the diuretic action of the Buxton waters was sound and would limit the number of gouty attacks whilst taking the waters.

BRITISH GYNÆCOLOGICAL SOCIETY.

The Germ Theory of Disease, with Special Reference to Gynæcology.

A meeting of this society was held on March 9th, Dr. Macnaughton-Jones, President, being in the chair.

Dr. Granville Bantock read a paper on the Modern Doctrine of Bacteriology, or the Germ Theory of Disease, with Special Reference to Gynæcology. He defined the modern doctrine of bacteriology as being this—viz., that in the majority of, or as some extremists held all, acute diseases the condition was due to the influence of a specific so-called pathogenic micro-organism. He proceeded to combat this view by propounding the very opposite doctrine, that the presence of these various micro-organisms was the result and not the cause of disease—in other words, that the disease furnished the conditions necessary for the presence of the special micro-organism. He referred to the experiments of Mr. George Stoker on the healing of wounds treated by oxygen gas which led him to the conclusion that in proportion as the staphylococci were numerous and well developed so the healing process progressed. The recent observations of Dr. H. D. Robinson showing that the gonococcus was present in 76 cases of vulvitis in children were quoted in illustration of the view that gonorrhœa was not due to the gonococcus. He criticised Mr. Lockwood's paper on Aseptic and Septic Surgical Cases and maintained that the presence of micro-organisms in the skin did not justify the description of the skin as being "septic." He pointed out, further, that Kopinski in a recent paper in the *Medical Press and Circular* stated that "in healing by first intention both saprophytes and pathogenic micro-organisms were present in the wound." Consequently he regarded the elaborate precautions now adopted in securing antisepsis and asepsis as a superfluous "ritual" which gave no better results than the observance of simple cleanliness. In conclusion, he claimed to have shown that the poisons of variola, vaccinia, and syphilis were not and could not be the product of a bacillus; that Löffler's bacillus was not a constant and therefore could not be the essential element for the production of an attack of diphtheria; that the essential element in the case of gonorrhœa was not the gonococcus; that the essential element in the case of typhoid fever was not the bacillus typhosus and that this bacillus could not live but a few hours in ordinary sewage; that not a single specimen of this bacillus had ever been discovered in sewer air and hence that typhoid fever could not be attributed to it because of its contained germs; that in the cases of the epidemics at Maidstone and King's Lynn there existed no proof of the contamination of the water by typhoidal matter, as indicated by the presence of the bacillus typhosus; that there was no evidence worthy of the name that tuberculosis was due to the ravages of the tubercle bacillus; that the comma bacillus could not be regarded as the essential element in the production of an attack of cholera and that the same could be said of the plague and its special bacillus; that the so-called pathogenic micro-organisms were constantly found under conditions consistent with perfect health and that in more than one notable instance they not only appeared to, but actually did, exert a beneficent influence.

Dr. Allan Macfadyen remarked that it was a unique experience to him to hear such theories as Dr. Bantock had propounded in Lister's country; he had come prepared to listen to, and to take part in, a serious discussion. The experimental research of the last 10 years did not appear to exist for Dr. Bantock nor had he brought forward one word of proof for the statements he had made. It was difficult to appreciate or deal with such an attitude of pure negation and he therefore abandoned any hope of convincing Dr. Bantock. Dr. Bantock had asked, "Where was the germ theory of disease now?" He replied that it stood exactly where it did before Dr. Bantock commenced his attack. He would leave it to the members of the society who were acquainted with the elementary facts of bacteriology to make their own choice as to whom they would follow—Pasteur, Lister, and Koch, or Dr. Bantock. If he were a guest of the society on some future occasion he would be pleased to discuss the questions raised in a more serious fashion than they had listened to that evening.

Mr. George Stoker said that his position was midway between two extreme views—on the one hand, that all micro-organisms in wounds were bad, and, on the other hand, that none were bad. He believed that some were harmful and some were useful, and in the latter class he included the staphylococcus. He had made observations on over 250 cases of ulcers and in all rapidity of healing was in proportion to the number of staphylococci present. He exemplified his remarks by illustrative cases.

Dr. R. T. Hewlett said that negative evidence such as Dr. Bantock had adduced was of little value unless overwhelmingly supported. With regard to the Maidstone epidemic Dr. Bantock was hardly fair, for he omitted to mention that from four to six weeks had elapsed between the date of infection and the commencement of the examination; and he ignored other epidemics, such as that at Worthing, where the typhoid bacillus had been isolated from the water. In diphtheria the bacillus could be detected in the membrane in the great majority of cases. The whole cycle of splenic fever could be observed in a lower animal and he could not see that anyone who investigated the matter could escape the conclusion that the bacillus anthracis was the causative agent. With regard to ovariotomy, he would remark that the peritoneum was exceptional and would suffer with impunity a treatment that would not be tolerated by any other serous membrane. Attempts to open the knee-joint without strict antiseptic precautions would end in disaster.

Dr. Inglis Parsons regretted that so distinguished a surgeon as Dr. Bantock should hold such erroneous views on pathology. No comparison could be made between a modern hospital like the Samaritan and one of the older hospitals. He instanced the practice of two surgeons when he was a student; one adopted strict antiseptic precautions and his results were excellent, and the other decried Listerism and had to give up certain operations because of the bad results Dr Bantock's practice refuted his theories

Mr BOWREMAN JESSETT contended that Dr Bantock in his former practice of using sulphurous acid in the treatment of stitch abscesses and in his present practice of boiling his silk ligatures practised antisepsis and asepsis Heat was the best disinfectant they had Would Dr. Bantock explain why he boiled his silk?

Dr CLEMENT GODSON thought it would be disastrous if Dr Bantock's paper had the effect of shaking the faith of midwifery practitioners in the employment of antiseptics In a Presidential address which he had delivered before that society, he had shown the marvellous change which had taken place in the City of London Lying in Hospital since the introduction there of corrosive sublimate Last year among 565 cases there had not been a single case of septicæmia It would be indeed sad to revert to a mortality of one in 19, which existed when he first became attached to that hospital; and he had no doubt that the change was due to the thorough use of antiseptics

Dr MACPHERSON LAWRIE declared himself an adherent of the germ theory of disease He thought that the address to which Dr Godson had alluded furnished overwhelming evidence in favour of the antiseptic treatment of disease

Dr C H F ROUTH referred to the historical incident of the elucidation of the cause of puerperal fever by Semmelweis in the Vienna Maternity and contended that his researches formed a strong proof in favour of the germ theory of disease

Dr P. Z HEBERT said that Dr Bantock had told them that germs were the result and not the cause of disease But disease was a condition, not a material entity Did Dr Bantock maintain that bacteria were produced *de novo* by disease? Or did he think they were formed out of the diseased tissues? If not, where did they come from since Dr Bantock denied their presence in the air?

Dr A W ADDINSELL did not think Dr Bantock could congratulate himself on his powers of prophecy, because the doctrine of bacteriology held the field more victoriously than 12 years ago, when Dr Bantock prophesied its speedy downfall With regard to Mr Stoker's experiments Dr Addinsell contended that the correct explanation was that in the wound treated with mercury the drug had killed not only the staphylococci but also the granulations on which healing depended The other ulcer healed because oxygen favoured the granulations and also diminished the virulence of the staphylococci This view was supported by experimental proof The absence of the gonococcus from a pus tube was no argument against the dependence of gonorrhœa on the gonococcus, for under certain conditions the latter lost its vitality

Dr H. JELLETT thought that Dr Bantock had overlooked two important points the first was the difference in virulence of bacteria which were morphologically the same, and the second was the immunity acquired by patients to the action of a particular form of bacteria as the result of the continued presence of that bacterium in the body One case in four in which the gonococcus was present in cases of pyosalpinx was a large proportion if they took into account the number of cases of sterile, of tuberculous, and of septic pus tubes Why did Dr Bantock wash his hands even to the slight extent that he did? Was it a mere ritual?

The PRESIDENT said that he was an adherent of Lister's teachings from the days of the impermeable shellac with carbolic putty dressing down to the present time He ridiculed the idea of drawing those distinctions made by Dr Bantock between what he called the "grosser forms of septic mischief" and the lesser Such teachings as those enunciated in the paper set back the hands of the clock so far as medicine was concerned some 25 or 30 years and they were all the more serious and dangerous because they emanated from one who was acknowledged to be a brilliant operator He could not help coming to the conclusion that Dr Bantock had not made himself fully conversant with the researches of bacteriologists within recent years The attitude of the society should be such that its verdict should be unmistakeable in repudiating the views they had heard

Dr BANTOCK, in reply, said that he was disappointed at the course the discussion had taken, for no attempt had been made to refute a single point in his paper. All the speakers avoided these points and while professing to be followers of Lister showed that they had taken no notice of his latest teaching but adhered to that of 20 years ago He was twitted with having avoided the typhoid fever epidemic at Worthing He could retort that his critic equally avoided the Maidstone epidemic, as to which Dr Poore in his Milroy Lectures substantially agreed with him

PATHOLOGICAL SOCIETY OF MANCHESTER

Ureteral Calculi Removed by Suprapubic Cystotomy —New Method of Staining —Exhibition of Specimens

A MEETING of this society was held on March 8th, Dr R B WILD, President, being in the chair

Dr KELYNACK, on behalf of Professor DRESCHFELD, showed a preparation from a case of Cardiac Rupture with Communication between the Ventricular Cavities

Mr STANMORE BISHOP showed Three Ureteral Calculi removed by Suprapubic Cystotomy Two cases occurred in males and one in a female The first, in a boy, aged 13 years, produced the usual symptoms of vesical calculus, was easily recognised by the sound, but was evidently fixed At the operation six years ago an oxalate of lime calculus of the shape of a wheatsheaf was found, the stalk being fixed in the lower end of the ureter Perfect recovery ensued and a report of good health was made last month The second case, a woman, gave a history of renal colic at intervals since the age of 13 years Menstruation commenced at 15 years After this the pain was accentuated at the periods Both ovaries and tubes had been removed a year previously by another surgeon but without relief Stone was detected by recto bimanual examination, it could not be felt from the vagina It was removed but the patient died from anuria In the third case, a boy, aged seven years, had complained of symptoms of vesical stone "since he was a baby" and a calculus weighing two ounces was found in the bladder and removed The patient, however, did not improve, the temperature rose, and there was still great pain Thinking that there might be an accumulation of pus in the cavum Retzii a rectal examination was made and a second stone was detected in the lower end of the ureter This was removed and at once allowed the exit of pus from the corresponding kidney The patient made a slow recovery Mr Stanmore Bishop discussed the symptoms produced by, and the various operations proposed for, ureteral stones impacted in this situation In reply to Dr Harris Mr Bishop pointed out that a satisfactory result from massage must be very exceptional, that in two of the cases under discussion it could not have been borne, and that in the third it would have been extremely risky

Dr ORR read a preliminary note of a New Method of Staining the Myelin Sheath of Nerve Fibres in the Brain and Spinal Cord The method consisted in the penetration with osmic acid of formalin hardened blocks of tissue to bring out the normal fibres, and should it be desired to stain the morbid fibres then the nervous tissues—as in Marchi's method—had to be previously hardened in bichromate of potassium, 2 per cent, or in Müller's fluid The blocks of tissue should not exceed one eighth of an inch in thickness The osmic acid was mixed with acetic acid in the following proportion osmic acid, 2 per cent, four cubic centimetres, acetic acid, 1 per cent, one cubic centimetre Formalin hardened pieces of tissue ought to remain in this solution for from four to six days, Muller or bichromate hardened nervous tissue for from 10 to 14 days Fresh tissue placed in the above solution for 48 hours and then immersed in 10 per cent of formalin demonstrated especially the fine fibres of the outermost layer of the cortex The penetration being completed the block was then embedded in paraffin and cut After removal of the paraffin from the sections differentiation was carried out by means of permanganate of potash, 1½ per cent and oxalic acid 1 per cent, except in bichromate hardened tissue the sections in this case being mounted after the paraffin had been dissolved out by xylol *Dr Orr* specially recommended the acetic osmic acid solution on account of the certainty with which it stained the fine medullated fibres of the brain and also on account of its superior penetrating power over Marchi's fluid in Muller and bichromate hardened nervous tissues The communication was illustrated by a series of lantern slides

The following card specimens were exhibited —

Dr ASHBY (1) Congenital Syphilitic Cirrhosis of the

Liver; and (2) Fractured Humeri from a child the subject of Scurvy-Rickets.

Dr. F. O. Moore: Some Morbid Infiltrations.

Mr. Westmacott: A series of models illustrating the effect of Nasal Obstruction on the Hard Palate.

LIVERPOOL MEDICAL INSTITUTION.

"*Bronchiolectasis.*"—*Multiple Rodent Ulcer.*—*Exhibition of Specimen.*

A meeting of the Pathological and Microscopical Section of this society was held on March 16th, Mr. F. T. Paul being in the chair.

Dr. R. Buchanan read a paper on "Bronchiolectasis." It was based on a case occurring in a boy, aged five and a half years, who died after several weeks' illness from an affection of the lungs believed during life to have been tuberculosis. At the necropsy no tubercle was found in any organ. The lungs had a "honeycomb" appearance, being riddled with minute holes averaging one-sixteenth of an inch in diameter. Dr. Buchanan then described minutely the pathology of his specimen and gave a *résumé* of the cases which had been described by other observers. His case seemed to show that the cavities were not true dilatations of bronchioles but rather vomical, due to breaking down of broncho-pneumonic foci and enlargement by ulceration. He also suggested the possibility that cases of this sort which were not fatal might be a connecting link between the catarrhal pneumonia of childhood and the bronchiectasis of later life or the non-tuberculous forms of fibroid lung. He suggested the term "ulcerative broncho-pneumonia" as preferable to "bronchiolectasis." The paper was well illustrated by microscopic specimens and lantern slides.—Dr. Barr argued that such cases were pyæmic, the cavities being originally embolic abscesses and not primarily within the air tubes. He described a case which he considered similar to Dr. Buchanan's and which was purely pyæmic, complicating a wound of the leg.—Dr. Warrington also remarked on the paper and Dr. Buchanan replied.

Mr. Paul read a note on Multiple Rodent Ulcer. He described three cases in which more tumours than one were present. In the first two the primary disease was situated on the nose and forehead respectively and in each had existed for nearly 20 years before secondary infection occurred. The secondary affection in both was in the submaxillary region, in the nose case on both sides, in the forehead case on one side only. In the third case there were three growths, all primary, one on the nose, one over the right external angular process, and one over the right mastoid. Microscopical examination of these showed that the first was a typical rodent ulcer, the second a beautifully distinct tubular adenoid carcinoma, while the third was a squamous-celled carcinoma. The note was illustrated by microscopic specimens and micrographic lantern transparencies.

Dr. W. T. Allen showed an exceedingly marked specimen of Fatty Degeneration of the Kidney.

Mr. C. G. Lee showed: 1. An Eye the Subject of Calcareous (or Osseous) Degeneration of the Choroid. It was removed from a man, aged 44 years, on account of trouble in the other eye. It had been blind for 40 years from a wound with a penknife. Mr. Lee thought that this and another case which he published some years ago supported the view that sympathetic ophthalmitis might arise from ciliary irritation without the aid of micro-organisms. He thought his case argued strongly against evisceration with implantation of glass globes. 2. An Eye removed from a child exhibiting Suppurative Choroiditis.

Mr. Douglas Crawford showed: 1. A Cyst removed from the Anterior Vaginal Wall of a woman, aged 27 years. 2. An Extra-uterine Gestation which had ruptured into the broad ligament. The last confinement was 19 years ago, since which there had been no pregnancy until this occurred. Besides the presence of the tumour the symptoms were slight. At the operation a large mass of clot was evacuated and the fœtus was from three to four months old and much macerated. No placenta or cord could be found.

Dr. Alexander showed a Hydrocephalic Brain.

Dr. G. G. Stopford Taylor showed a Squamous-celled Melanotic Carcinoma originating in a mole. The pigment was chiefly contained within the epithelial cells.

Mr. Hawkins-Ambler showed (1) the Appendages from a case of Pyosalpinx; and (2) a Microscopic Specimen of a Simple Papilloma removed from the labium minus of a child, aged six years.

Dr. J. Wiglesworth showed: 1. A specimen of Stenosis of the Ileum caused by a Healing Tuberculous Ulcer. It was obtained from the body of a woman, aged 44 years. The constriction would only admit the tip of the little finger and was situated a foot and a half above the ileo-cæcal valve. Below the stricture were several other tuberculous ulcers and the lungs were also affected. 2. A kidney with two perfectly distinct ureters.

Mr. W. B. Bennett showed an excellent specimen of "Madura Foot" well exhibiting the inter-communicating cysts and sinuses filled with dark granular material.

Dr. Warrington showed some Microscopic Specimens and Drawings from a case of Caries of the Spinal Column in which the cord above the lesion showed some marked and interesting ascending degenerations.

The specimens were discussed by Mr. Paul, Mr. George Hamilton, Dr. Robert Hamilton, Mr. Bickerton, Dr. Bennett, Mr. Lee, and Dr. Wiglesworth.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of State Medicine.

Tuberculosis.

A meeting of this section was held on Feb. 17th, Dr. H. C. Tweedy, the President, being in the chair.

Dr. Grimshaw read a paper on the Prevalence of Tuberculosis in Ireland and the Measures necessary for its Prevention. He reviewed the principal statistics of tuberculosis, and especially of phthisis mortality in Ireland, the analysis being mainly founded on a table of the deaths from tuberculosis in children under five years of age and of phthisis at the various ages of active life from 15 to 45 years in town and country districts. During the three years dealt with in the table—1895, 1896, and 1897—the average annual death-rate from all causes for Ireland was 17·3 per 1000; the rate for the town districts (that is towns with a population of 10,000 and upwards) was 25·4, and for the rest of Ireland 15·2. For Ireland the death-rate from all tuberculous diseases, exclusive of phthisis, was 0·7 per 1000; for country districts 0·4, for town districts 1·5, or nearly four times the latter rate. For phthisis alone the rates were for Ireland 2·0; for country districts 1·7, for town districts 3·3, or nearly double the usual rate. Taking all forms of tuberculous disease the rate for Ireland was 2·7; for country districts the rate was 2·1, for town districts 4·8, or more than double. Phthisis alone caused 11·7 per cent. of all the deaths in Ireland during the period under consideration, the percentage for the districts with towns of over 20,000 population being 13·3, for those with towns of 10,000 inhabitants and upwards 13·2 or slightly less, as compared with 11·1 per cent. for the rest of Ireland. The proportion of deaths from phthisis to total deaths is therefore very high even in the country districts of Ireland. The age at which phthisis causes the greatest proportion of the total mortality in Ireland is from 15 to 25 years, and the percentage of deaths to total deaths during this period is 44·6 per cent. in Dublin, 55·4 per cent. in Belfast, 54·4 per cent. in Cork, 56·3 per cent. in Limerick, 52·5 per cent. in Londonderry, and no less than 58·6 per cent. in Waterford.

Dr. Martley read a short paper on the Death-rate from Tuberculosis, as exemplified in the male population of England, for the five years 1891–95.

Dr. McWeeney read a paper on the Bacteriological Aspect of Tuberculosis. With regard to the morphology of the tubercle fungus he had never failed to detect genuinely ramified forms in sputum whenever he had leisure to seek them out. The type of ramification was that of the genus cladothrix, and from the researches of Firchel, Coffin Jones, Hazo Bruns, and Ledoux-Lebard, there could be no doubt of the biological affinity of the tubercle fungus with streptothrix and actinomyces. The staining reaction long considered to be peculiar to the tubercle and leprosy bacilli was now known to be shared by a smegma bacillus, and by the pseudo-tubercle bacilli isolated by Mockler and others from cowdung, by Mockler from the leaves of timothy grass near the Görbersdorf Sanatorium, and by Rabinowitsch from butter. The cause of the staining reaction was the presence in the sheath of the bacillus of a peculiar wax, as was shown last year by Aronson This underwent gradual extraction by alcohol and ether, with the result that the bacilli lost their specific staining reaction The discovery by Ledoux Lebard of the bacillus of fish tuberculosis and the recently demonstrated inoculability of poikilothermous animals with a variety of a bacillus capable of thriving at ordinary temperatures were *important recent additions to our knowledge*

Dr P. LETTERS read a paper on the Distribution of Tuberculosis in Ireland By statistical tables he sought to prove that tuberculous disease throughout Ireland—tabes mesenterica and tuberculous meningitis more so than phthisis—was regulated almost exclusively by aggregation of population Small towns and villages bred tuberculosis largely. The most tuberculous region in Ireland extended along the eastern and south eastern seaboard and was mapped out by the counties of Antrim, Down, Dublin Wexford, and Waterford The least tuberculosis was found *in a compact region in the north west comprising* the five contiguous counties of Donegal, Leitrim, Cavan, Fermanagh and Longford These two regions contain respectively a high and a low percentage of urban population

---

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on March 10th, Dr J Gwynn, President, being in the chair —Dr A Ashby read a paper on the Duties of Medical Officers of Health in Relation to Small pox in view of the Alterations in the Law of Vaccination The hope expressed by those who had forced this "tremendous experiment' on the country for five years that it would disarm opposition to vaccination, had not been fulfilled and in many cases vaccination had been practically abolished He did not deny that there were a few improvements in the law, but Clause 3 which imposed on the *magistrate the invidious duty of deciding whether objec*tons were "conscientious' was absurd Again, it seemed anomalous that a matter closely connected with the public health should be committed to the Poor law and not to the sanitary authorities, though it would be inexpedient at the present time to effect a change which might lead to the election of these authorities being dependent on their opposition to vaccination But medical officers of health should endeavour to secure isolation accommodation where such had been deficient or wholly wanting, but elsewhere should small pox break out with a severity previously unknown and the accommodation which had sufficed in the past prove inadequate the people must pay in hasty and therefore costly provision for their neglect of the easier and inexpensive protection of vaccination Adults might be left to suffer for their own folly, but the infants should not be sacrificed to that of their parents and *in the absence of compulsion* organisation *should* be opposed to organisation, branches of the Jenner Society should be established everywhere especially where the *Anti vaccination League was at work*, and the *public* educated by lectures, the distribution of literature, &c The coöperation of men and women of all classes should be encouraged, but the medical officer of health would do well to avoid involving himself in heated newspaper controversies —Mr Beale Collins said that in his district only 12 objectors had come forward in a population of 35 000 and vaccinations had increased since the passing of the Act — Dr Woodforde told how the improvised accommodation required by an outbreak of 50 cases in a rural district cost £1500 —Dr E Groves found great difficulty in getting a site for a tent and complained that the Local Government Board would not allow the reception of even real paupers in the workhouse infirmary —Dr F T Bond felt that little could be done *save during an epidemic At Gloucester* the sanitary authority was now mostly composed of anti vaccinationists, who, though professing to rely on isolation had actually reduced the accommodation from 48 to 16 beds in an iron building with no road or proper arrangements —Dr Seaton found hospital provision no less *unpopular* than vaccination, and the *Local Government* Board instead of compelling the authorities to provide it placed obstacles in the way of such as were willing Guildford had to fight from court to court for the erection of a hospital in one of the loneliest spots in the county, the opposition coming from a single resident at a distance of two miles —Dr McVail considered it impossible to define sufficient accommodation, for where all were vaccinated amount would suffice There should be a permanent and complete administrative block with ample space and facilities for the erection of temporary buildings to meet the requirements of the occasion —Dr Sykes thought that the public being unable to appreciate the differences of degree in vaccinations and of type in small pox it would be well to confine oneself to crude statistics in discussions of the subject He felt very strongly that the whole system of certification of vacci*nation as well as of the causes of all deaths needed revision* The mere fact should be reported by the friends, but the certificate describing the result of a vaccination or the cause of a death should be, as in the notification of infectious diseases, forwarded by the medical attendant to the respective authorities

EPIDEMIOLOGICAL SOCIETY.—A meeting of this society was held on March 17th, Dr Franklin Parsons President, being in the chair —Mr W H Crosse, consulting medical officer of the Royal Niger Company, read a paper on Blackwater Fever, or Hæmoglobinuric Fever the first instalment of which we publish on page 821 —Dr Manson said that he believed in the daily use of from five to 10 grains of quinine as a prophylactic, and mentioned the case of a missionary who during a residence on the west coast of 14 years had neglected this precaution on three occasions only and each time had an attack of fever, *from* which he had otherwise enjoyed exemption Koch had called attention to the fact that in East Africa negroes coming from the interior who lived with and like the Europeans suffered to some extent and that generally the natives were immune to the fevers of their own district but not to those of others It should be remembered *that the presence of a parasite did not* prove it to be the cause of a disease, plasmodia were often found in persons suffering from typhoid fever since malaria predisposed to though it had no connexion with, enteric fever In China he had seen many cases of severe malaria and extreme cachexia but never accompanied by black water Either some other factor was required or the plasmodia acquired different properties according as they had passed through the bodies of one or other species of mosquito He might mention the case of a man who during a febrile attack after his return home passed black urine but the colour was shown to be produced by an enormous excretion of indican, neither hæmoglobin nor albumin being present —Dr Harford Battersby enjoined caution in diagnosis, having himself observed epidemics in which the urine was almost black from bile pigments and blood, but which was not hæmoglobinuric, that in which Bishop *and Mrs Hill died* with about 50 *other* Europeans was true yellow fever The paludal fevers of Africa were far less distinctly remittent than those of other regions Blackwater fever was certainly on the increase but seemed invariably to follow chills indiscretions, or exposure to freshly turned up soil Vomiting was not a constant symptom, he had not vomited in any of his three attacks though he *had melæna* — Mr Craister had taken quinine daily during his five years on the Niger and he had only three very slight attacks of fever and none of blackwater *fever* He had not lost one of the 11 cases of hæmoglobinuric fever in which he had given quinine from the first, or saved one of the six or seven in which he could not, they having been attacked while away up the river — Dr Washbourn from his study of paroxysmal and experimentally induced hæmoglobinuria could entirely confirm Mr Crosse s explanation of the phenomenon At first the liver transformed the hæmoglobin into bile pigment, but when the *quantity* exceeded the power of the liver the excess passed out by the kidney —Mr Pakes referred to the Texas fever among cattle which was attended with hæmoglobinuria and perhaps also hæmaturia, and in which large doses of quinine were beneficial The action of habitual small doses of quinine was not exerted on the plasmodia so long as they were enclosed *within the* blood disc, but when having sporulated and burst its walls the numerous progeny of the original plasmodium escaped, they were attacked and killed before they could invade other discs Already seven varieties of plasmodia had been distinguished by Italian and German investigators and if only one or two of these had the power of inducing hæmoglobinuria *their geographical* distribution, independent of the malignancy of local malarial fever, was easily explained

OXFORD MEDICAL SOCIETY.—An ordinary clinical meeting of this society was held on March 11th in the Radcliffe Infirmary, Mr H P Symonds, President, being in the chair —Dr Ritchie read notes of a case of F rhage and showed the brain which hæmorrhage on the surface of the pons; on section a very extensive hæmorrhage was found ploughing up the whole substance of the pons. The cerebral arteries were markedly atheromatous. The patient, a woman, aged 48 years, had attended a hospital as an out-patient to be treated for a skin affection when she suddenly became helpless with some spasmodic twitching of the left eye. She rapidly became unconscious and sank four hours after her admission. The pupils were noticeably contracted before death and the temperature rose to 105° F. There was no atheroma of the heart or large vessels corresponding to that found in the cerebral arteries, but there was some interstitial change in the kidneys, with considerable periarteritis. No history of syphilis was obtained.—Dr. Turrell read notes of a case of Placenta Succenturiata. A woman, a primipara, fell out of a dogcart when six months pregnant. She was delivered at full term, the labour being natural and easy; the placenta was complete and of normal size. 24 hours after, the patient being in great pain, the uterus was found to be distended with clots. These were expressed, but the hæmorrhage continuing the uterus was explored and two pieces of placenta of the size and shape of bananas were removed. The patient remained very collapsed and bloodless, with a pulse of 150 and a temperature of 102° F. A douche was given which was followed by a rigor. On the following day, the discharge being a little offensive, the uterus was explored under an anæsthetic and a few shreds were removed from the fundal region. A douche was administered which was again followed by a rigor. These were the only rigors which occurred during the progress of the case and on each occasion followed the douching. The temperature fluctuated above normal for a fortnight, but the patient ultimately made a good recovery. Dr. Turrell drew attention to the fall which the patient had during pregnancy, as from what was known of the etiology of placenta succenturiata it was probable that this gave rise to hæmorrhage into the placental tissue with destruction of some of the villi. Dr. Brooks suggested that the rigors were due to absorption of perchloride of mercury, but Dr. Turrell on the second occasion had used an iodine lotion. He regarded it as a reflex phenomenon.—Mr. Symonds read notes of two cases of Appendicitis in which he had successfully operated and showed the patients. One of them, a woman, aged 22 years, had had three or four mild recurrent attacks before admission and before operation there was distinct tenderness at McBurney's point. The appendix was slightly adherent to surrounding structures and was much elongated, passing up under and adhering to the under surface of the liver. It was removed by circular amputation, the peritoneal surfaces being sutured with silk. Recovery was uneventful. The second case was also one of mild recurrent appendicitis in a woman, aged 23 years; the appendix was inflamed and adherent to surrounding tissues and was removed in a way similar to the above; the patient made a good recovery.—Dr. Duigan showed a specimen of Vesical Calculus weighing four ounces which was found post mortem in the bladder of a young man who had refused all surgical treatment.—Dr. Elsmore showed a Skiagram of a Broken Needle embedded in the Wrist.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 2nd, Dr. Alfred Robinson, President, being in the chair.—Dr. Keeling showed the specimens removed and gave details in the following cases:—1. Cystic Myoma of the Uterus successfully removed by abdominal section in an unmarried woman, the uterine wound being treated intra-peritoneally. 2. Dermoid Cyst and Ovary. The patient was single; recovery was good. 3. Broad Ligament Cyst removed from a married woman, aged 30 years. The patient was sterile and had been married 10 years; recovery was excellent. 4. Menstrual Fluid removed in a case of Imperforate Hymen. The patient, otherwise a healthy well-grown girl, was 17 years of age and had never menstruated. 5. Cancerous Uterus removed by vaginal hysterectomy from a married multipara, aged 42 years. Recovery had been excellent with the serious exception that a urinary fistula had resulted probably from the bladder having been caught by one of the forceps used in securing the broad ligaments.—A discussion followed on the Operative Treatment of Fibromyomata and Cancer of the Uterus in which Dr. J. W. Martin, Mr. Richard Favell, Dr. Andrew Walker, Dr. Sinclair White, Mr. Pye-Smith, and Mr Sidney Barber took part.—Dr. Cairns read notes and showed the specimen of a case of Ectopic Gestation diagnosed by Dr. Andrew Walker and himself and successfully operated on by Dr. Sinclair White.—Dr. Arthur Hall showed the following specimens:—1. Heart with Stenosis of the Pulmonary Artery, Imperfect Ventricular Septum, and Patent Ductus Arteriosus, from a boy, aged 11 years, who died from pneumonia. The cyanosis was not extreme except during the last few days of life. 2. Liver with Gall-stones in the Gall-bladder, an Impacted Stone in the Ductus Choledochus, and several Stones in the Intrahepatic Bile-ducts which were largely dilated. In the left lobe were multiple abscesses secondary to well-marked cholangitis. At the left extremity of the liver there was a large subphrenic abscess which seemed to be secondary to the suppuration in the left lobe. 3. Carcinoma of the Bodies of the Seventh Cervical and Upper Three Dorsal Vertebræ—part of a widely-distributed cancer the primary seat of which was not discovered. The bodies of the vertebræ had given way and produced transverse myelitis which was the immediate cause of death. 4. Typhoid Ulcers preserved by Kaiserling's method with formalin and glycerine.—Dr. George Wilkinson gave an account of a case of Subphrenic Abscess operated upon by him. The patient, a man, aged 47 years, was admitted into hospital very ill with a prominent, tense, fluctuating swelling in the epigastric region. Hepatic abscess was diagnosed, the swelling was incised, and two pints of pus and hydatid fluid were evacuated. The patient complained of much pain in the left side when being lifted on to the operating-table. Next day there were signs of a subphrenic collection of fluid in the left side. This was evacuated and drained after resection of a portion of the seventh rib in the anterior axillary line and suture of the costal pleura to the diaphragm. Drainage was continued for two months after which the cavity healed and the patient was discharged.

CHELSEA CLINICAL SOCIETY.—A meeting of this society was held on March 7th in the theatre of the Jenner Institute, Mr. J. Foster Palmer, President, being in the chair.—The President, in a few opening remarks, offered the thanks of the society to Dr. Allan Macfadyen for granting them the use of the theatre. Referring to the subject of the lecture they were about to hear he said that though the society was a clinical society, yet that bacteriology was the handmaid of clinicology. He then called upon Dr. Macfadyen for his lecture upon Enteric Fever and Diphtheria.—Dr. Macfadyen, in the course of his lecture, dealt mainly with the bacteriological aspects of these diseases. The life-history of the typhoid fever bacillus was discussed in its different phases and cultures of the organisms on various soils were shown. The spleen and urine were stated to be the most convenient sources of pure cultures of the bacillus, the search for it in the dejecta being attended with considerable difficulty. The Elsner potato-gelatin soil had not proved so successful a means of isolating the bacillus from the stools as had originally been anticipated. The means adopted for differentiating between such closely allied organisms as the typhoid and colon bacillus were explained and illustrated. The sources of infection were next dealt with and the pathological lesions found in the disease, whether due to primary or to secondary infections, were explained. The bacillus had undoubtedly pyogenic properties. Pfeiffer's phenomenon and Gruber's reaction were discussed and the great value of Widal's test in doubtful cases of the disease was emphasised. All these reactions were stated to be of a specific character and for the successful employment of the Widal test a good strain of the typhoid bacillus was said to be essential. The difficulty experienced in obtaining any specific toxins from cultures of the organism had up to the present prevented the preparation of an antitoxin serum of any value for treatment; on the other hand, the anti-typhoid "vaccines" proposed might be of value as preventive agents. The salient points connected with the bacteriology of diphtheria were then referred to. The antitoxin treatment was discussed and the importance of an early bacteriological diagnosis and the immediate use of the serum treatment were pointed out. Through improved methods of preparation the amount of serum necessary for injection had been greatly reduced and thereby the danger of any unpleasant sequelæ reduced to a minimum. The methods of standardising the serum were explained and it was stated that it was an erroneous impression that the antitoxic substances had any poisonous or deleterious action on the system. The lecture concluded with a lantern demonstration and an exhibition of a number of microscopical specimens in illustration of the subject matter of the paper.—A discussion followed in which Mr. Lennox Browne, Dr. C. J. Harrison, Dr. Woulfe Flanagan, Mr. J. Marsh, and Mr. E. Vinrace took part.

Reviews and Notices of Books.

The Ophthalmology (Liber de Oculo) of Petrus Hispanus (Peter of Lisbon), subsequently Pope John XXI. The Latin text edited and translated into German by Dr. S. M. BERGER. Munich: J. F. Lehmann. 1899. Pp. 135. Price 3*s.*

THE editor of this interesting little volume states that the original only exists in manuscript and that in printing the text and translation he has availed himself of opportunities of collating the copy in the Royal Bavarian Library in Munich with those in the Florentine, Parisian, and Roman libraries. Petrus Hispanus was the son of a physician named Julian and acquiring a thorough knowledge of medicine practised for some time as a physician with great success. He afterwards entered holy orders, became Archbishop of Braga in Portugal, was made Cardinal in 1273, and on the death of Adrian V. he was elected to the Pontifical dignity on Sept. 13th, 1276, as Joannes XX., though in his epitaph at Viterbo he is called Joannes XXI. He died in 1277. He wrote several works on medicine. The present one on ophthalmology is referred to by one of the fathers of French surgery, Guy de Chauliac, who wrote in the early part of the fourteenth century. Petrus Hispanus commences with sufficient lowliness by stating that he is the humblest of physicians. He describes the eye as a round, noble, and brilliant organ composed of seven membranes and three humours and his description of these is comprised in a very few lines. The physiology of vision is in accordance with the imperfect physical knowledge of the time and vision is held to be something streaming from the eye. He gives a curious list of the diseases of the eye—viz., inflammation, hydrophthalmus, hard swelling, itching membranes, leucoma, cancer, swelling, water, illusions of vision, bursting of the globe, stony tumour, adhesion of the lids, eversion of the lids, lagophthalmus, distichiasis, phtheiriasis, hordeolum, inversion of the lashes, eczema, herpes, glandular tumour, loss of eyebrows, golden yellow tumour, and chalazion. He asks, What is "obtalmia"? and answers that it is an inflammation with generation of heat of the conjunctiva and gives its etymology as *ob*, against, and *talmon*, eye; hence something acting injuriously on that organ. The treatment recommended for "obtalmia" is rest, sleeping with the head elevated in a darkened room, refraining from conversation, coitus, and exposure to smoke and dust, abstinence from green vegetables, garlic and peppery diet, quarrelling and disputing, and from roast and baked food. When it is dependent on conditions of the blood venesection and the administration of Cassia fistula and Prunus damascena internally are recommended, whilst decoction of Trigonella fœnum græcum and violet leaves should be applied topically. Local applications, he observes, should be frequently renewed, as he knew of a case where a bandage was kept on for three days and a wound of the eye from a blow suppurated. Together with many drugs still in use, such as mallow, valerian, aloes, myrrh, squills, and cumin, several curious remedies are ordered, as the blood of a goat, the lungs of the goat or ox, the blood of a bat, woman's milk, and oil in which lizards have been thrice boiled, and he vaunts as a special wonder-working secret a substance which will cause the physician, who can and will make it, to be called not a physician but a prophet. This is a mixture of silver filings with those of copper, iron, lead, steel and gold, and storax, the proportions of which, he rather prudently adds, may be modified according to the finances of the patient. The mixture of filings and storax is to be placed for a day in the urine of a boy, on the second day in warm white wine, on the third day in fennel juice, on the fourth in white of egg, on the fifth in the milk of a woman brought to bed of a boy, on the sixth in red wine, on the seventh in the whites of seven eggs all of which are to be poured into a retort, the fluid distilled, and the distillate kept in a gold or silver cup. The prescription is to be kept secret, for its value is simply inestimable. Elsewhere the use of the patient's own urine and saliva and even of powdered *fæces of the lizard is* recommended.

The editing of the volume has been excellently accomplished. The upper half of each page is occupied with the original manuscript, the lower half gives a German translation with the Latin names of the plants specified, and there is a capital bibliography. The book will be read with interest by all who have a taste for archæology.

Squire's Companion to the British Pharmacopœia. Seventeenth edition. Revised by PETER WYATT SQUIRE, F.L.S., F.C.S. London: J. & A. Churchill. 1899. Price 12*s.* 6*d.*

THE new edition of this well-known book has not been produced with unseemly haste. It is nearly a year since the new Pharmacopœia was rendered accessible to all who wished to consult it prior to actual publication. The changes *in description, in* processes, and *in dosage* were so numerous and so important that the labour of incorporating them in the Companion and of producing a commentary must have been considerable. The task of incorporation has been very thoroughly performed and we congratulate the author upon the fact. So far as we have been able to test no statement of fact in the body of the Pharmacopœia has been omitted from the Companion. If the running commentary is less forcible than usual this is to be reckoned to the credit of the Pharmacopœia. Independently of his own experiments, the author has included numerous references to criticisms and suggestions which have appeared in the chemical and pharmaceutical journals, and in some cases these criticisms contradict each other. But it is none the less valuable to have them all recorded in one volume. As in former editions this volume contains much valuable information concerning remedies included in foreign pharmacopœias, *while the newest candidates for favour* receive adequate recognition. The inclusion of therapeutic references and of prescribing notes will prove serviceable to practitioners, since the best modes of prescribing and dispensing so often need a helping hand. A new section on Therapeutic Agents of Bacterial Origin has been written by Dr. R. T. Hewlett and contains indications for dosage, together with numerous references to recent literature. The volume as a whole not only contains a vast amount of interest for prescribers and dispensers, but it also supplies innumerable references to sources of detailed information. It is obviously the outcome of care and knowledge, and consequently earns a position of authority.

The Blood: How to Examine and Diagnose its Diseases. By ALFRED C. COLES, M.D. Edin. With six Coloured Plates. London: J. & A. Churchill. 1898. Pp. 260.

SO much advance has been made in recent years in our knowledge of the condition of the blood in disease that a small work on the subject dealing with it in a manner suitable for the clinician and not for the pathological histologist only is certain to be welcomed. Such a want Dr. Coles has attempted to supply, and all who read the book must feel that he has admirably succeeded in his endeavours. The methods of examining the blood are first detailed and the processes described are easy to follow and do not require a very complicated set of apparatus.

The general morphology of the blood is next considered. Dr. Coles possesses the happy knack of expressing what he means in simple words and without the introduction of unnecessarily numerous new scientific terms. Unfortunately, the many investigators who have made a study of the corpuscular elements of the blood have not adopted any uniform nomenclature and consequently a large number of terms have found their way into medical literature all designating the same thing. Thus the leucocytes most commonly met with in the blood have been variously named multinucleated leucocytes, neutrophile cells, or leucocytes with granules (Ehrlich); finely granular oxyphile or acidophile cells (Kanthack); the oxyphile cells (Gulland); microphagocytes (Metchnikoff); cells with finely granular protoplasm (Max Schultze); and leucocytes of the second variety (Hayem). This confusion is to be regretted, but Dr. Coles has collected all the synonyms and placed them at the head of each section so that reference is materially facilitated. The part of the book, however, which will be most thoroughly appreciated is that devoted to the Pathology of the Blood. The various diseases characterised by changes in the blood are described seriatim. This gives a much better idea of the value of an examination of the blood than if the usual plan had been adopted of mentioning the diseases in which certain corpuscular changes are found under the description of these changes. Primary or Idiopathic Anæmia is first considered. Under this heading we find a number of important pathological conditions, such as progressive pernicious anæmia (the differential diagnosis being especially well studied), leucocythæmia, lymphatic leucocythæmia, Hodgkin's disease, and splenic anæmia. This section is concluded with a differential chart of the most important forms of anæmia. Next we find described Secondary or Symptomatic Anæmia, such as that due to malignant disease and hæmorrhage.

Malarial Parasites naturally receive due consideration and then follow a series of sections on the Blood in Acute Diseases, such as pneumonia and typhoid fever. The chapter on the Condition of the Blood in Various General Diseases, such as diabetes, gout, myxœdema, &c., also contains much useful information.

The illustrations are nearly all original and are beautifully executed and reproduced. The whole work is very readable and will doubtless receive the appreciation which it deserves.

LIBRARY TABLE.

Notes on Essential Oils. By T. H. W. IDRIS, F.C.S. London and Bristol: Geo. Du Boistel and Co. Pp. 193. 1898.—The essential oils are complex compounds and their chemistry is by no means clear at the present time. The printed information, however, on the subject is somewhat widely scattered through scientific literature and Mr. Idris is entitled to a word of thanks for placing in collective form all that is known of the composition, chemistry, and analysis of these very interesting bodies. It seems probable that as our knowledge of the composition and constitution of essential oils increases we shall be able to anticipate nature and to construct them by a synthetic process. It will, indeed, be a chemical triumph if we are able at length to construct oil of roses or of lavender from turpentine, yet the proximate composition of these bodies is very similar. This little book is an interesting and valuable contribution on the subject and will prove a very handy source of reference. In an appendix a useful table of constants is given.

Physical Chemistry for Beginners. By Dr. C. M. VAN DEVENTER, with a Preface by J. H. VAN 'T HOFF. Translated by R. A. LEHFELDT, D.Sc. London: Edward Arnold. Pp. 146. Price 2*s.* 6*d.*—The study of chemico-physics is equal in importance to the study of pure chemistry itself. Indeed, so far has our knowledge of the constitution and structure of bodies been advanced that but a poor idea of the science would be gained without understanding the physical principles underlying this knowledge. The application of physical methods to the determination of molecular weight and the number of atoms in the molecule affords evidence on this head. Again, by studying the nature of that interesting and peculiar phenomenon of solution further light has been thrown on the architecture of molecules. This book, which is translated from the Dutch, fills a distinct gap. There have, of course, been published large volumes on the subject of physical chemistry—as, for instance, those of Ostwald and Victor Meyer—but these are much too advanced for those who have simply skimmed through mathematics and physics. At the same time the treatment of this section of the subject can scarcely be adequately done in the ordinary chemical text-book. The book, in fact, does not assume that the reader is very deeply acquainted with certain mathematical principles. And thus it has been written to meet the needs of students of medicine and pharmacy as well as those of chemists. It should well fill this excellent educational purpose.

Testing Milk and its Products. By E. H. FARRINGTON and F. W. WOLL, of the University of Wisconsin. Fourth Edition, Revised and Enlarged. Madison, Wis.: Mendoza Book Co. 1899. Pp. 236. Price $1.—This is a manual intended for dairy students, creamery and cheese-factory operators, food chemists, and dairy-farmers. It deals most exhaustively with the chemical analysis of milk, butter, and cheese. It omits any reference to the bacteriological diagnosis of dairy products. A good deal of space is devoted to praising the process known as the Babcock test for milk and the frontispiece is the portrait of the inventor of this test which essentially depends upon the separation of fat after treating the milk with certain reagents in a centrifugal machine. The centrifugal process certainly facilitates the accurate estimation of the fat in milk. It can be conducted by any ordinary individual without any special analytical knowledge. The book is sure to be in demand by those engaged in the industry.

The Baths of Mondariz.—We have received an illustrated guide to, and description of, the mineral waters of Mondariz. This is a popular health resort situated in Galicia. Perhaps the best idea of its position will be given to our readers if we say that it is not very far from Santiago. The bathing establishment, which seems very complete, is owned by two brothers named Peinador and the waters are of the alkaline carbonate type containing also a little iron. Good effects are said to have been obtained in lithæmia and sundry skin affections. Spain is an almost unknown land to the majority of English people, but even apart from its wealth of mineral water it is a very delightful country to visit. Those who love art, history, architecture, or scenery, to say nothing of courtesy and cheapness, will find their desire fulfilled in Spain.

JOURNALS AND REVIEWS.

Edinburgh Medical Journal.—The opening article of the March number is on the Treatment of *Ozæna*, with special reference to cupric electrolysis. It is written by Dr. P. McBride who states that Garrigou-Désarènes is said to have introduced *the method in question.* In 1895 the Society of

Belgian Laryngologists and Otologists appointed a committee of investigation. Dr. McBride thinks that cupric electrolysis has not yet been touched upon in English literature. He began to experiment with it in 1897 and now describes eight cases occurring among out-patients. He employed a current varying in strength from three to 10 milliampères, rarely exceeding the latter. Cocaine was used in most instances, if not in all, and after cleansing the nostrils the copper needle attached to the positive pole was inserted into the inferior or middle turbinated bone—sometimes into the tissues lining the middle meatus, while the platinum or steel needle was passed into the septum. Each sitting lasted about 10 minutes. Four of the eight patients were practically cured for long periods extending to 18 months. Dr. E. M. Brockbank writes on the Causation and Rhythm of the Crescendo Murmur of Mitral Stenosis, meaning thereby the murmur usually called presystolic. Altogether there are eight original articles.

Dublin Journal of Medical Science.—The original communications in the March number are on the Prevalence of Tuberculosis in Ireland (by Dr. T. W. Grimshaw, Registrar-General for Ireland), on Mallaranny as a Health Resort (by Dr. F. J. B Quinlan), and a further instalment of the articles on Public Health and Preventable Disease (by Dr. Patrick Letters).

Analytical Records

FROM

THE LANCET LABORATORY.

(1) EXONIA MALT EXTRACT; (2) AMBROSIA; AND (3) AMBROSIA PASTILLES.

(EVANS, GADD AND CO., FORE STREET, EXETER, AND REDCLIFT STREET, BRISTOL.)

WE have noticed these preparations on a previous occasion, but there are some fresh points about them worthy of record. "Exonia" is the comparatively new name of the extract of malt made by this firm. It is exceedingly active amylolytically. It possesses an agreeably malty flavour and is attractively light in colour. The bottle in which this preparation is contained is provided with a cap which represents an arrangement which has long been wanted for the convenience of measuring definite quantities of sticky viscid preparations like malt extract. The cap is provided with a metal slide which when opened allows the extract to escape, while when the cap is smartly shut the flow is neatly cut off and there is no unpleasant dribbling of the liquid down the sides of the bottle. The extract is contained in the "Ambrosia" pastille which consists of a gelatin lozenge possessing a very agreeable flavour of freshly prepared malt. "Ambrosia" is a combination of "Exonia" with Devonshire cream. This forms a perfectly homogeneous mixture in which separate fatty particles cannot be distinguished until water is added. It is a very palatable compound and should possess distinct therapeutic value akin to the similar combinations of active malt extract with cod-liver oil.

TUBORG BEER (BREWED IN DENMARK)

(THE TUBORG LAGER BEER AGENCY, NEWCASTLE-ON-TYNE.)

It was in the Carlsberg laboratories at Copenhagen that Professor Hansen made his important discovery of cultivating single species of yeast so that by employing a pure culture in the brewing of beer a sound and always uniform product could be ensured. The application of this discovery to the brewing of beer on the continent accounts largely for the rapid advances and improvements made in the brewing processes there. The beers under analysis are evidence of the importance of this discovery and of the excellence of the results obtained by its application. The analyses of the specimens submitted to us were as follows:—Wiener-öl beer: malt extractives, 3·78 per cent.; mineral matter, 0·21 per cent.; alcohol, by weight 4·00 per cent., by volume 5·00 per cent., equal to proof spirit 8·77 per cent. Lager beer: malt extractives, 4·26 per cent.; mineral matter, 0·28 per cent.; alcohol, by weight 4·00 per cent., by volume 5·00 per cent., equal to proof spirit 8·77 per cent. Tuborg beer for export: malt extractives, 3·35 per cent.; mineral matter, 0·14 per cent.; alcohol, by weight 5·87 per cent., by volume 7·32 per cent., equal to proof spirit 12·84 per cent. We need make but little comment on these results. The specimens were quite bright and in sound condition. They are desirably light in character, showing a low alcoholic strength, and the taste was delicately bitter. The absence of objectionable preservatives and of bitter substitutes was ascertained.

ERASMIC SOAP.

(J. CROSFIELD AND SONS, LTD., WARRINGTON.)

A very delicate test showed that the materials in this soap are well balanced. There was no trace of free alkali. The soap is well milled and desiccated and yielded a full creamy lather. It is made delicately fragrant with essential oils. The soap basis is excellent and evidently composed of the choicest materials.

ST. LEGER MINERAL WATER (POUGUES)

(AGENTS: VOIGT, BARTON AND CO., 25, GREAT TOWER STREET, E.C.)

This water drawn from the St. Léger spring in the province of Loire, France, holds the reputation of affording benefit in urinary diseases as well as in gastro-intestinal dyspepsia. Pougues is counted amongst the health resorts and spas of Europe. We find that the water is slightly sparkling with an excess of carbonic acid gas. It is practically free from iron. It contains 2·37 grammes per litre of saline constituents, foremost amongst which are sodium carbonate 1·59 grammes, and common salt 0·19 grammes, the difference being made up by lime and magnesium salts. It further contains some sulphate of soda and distinct traces of lithium salts. It is an alkaline carbonated water, sedative and antacid. A course of the waters of the composition just described is well known to give benefit to patients inclined to gastric and urinary disorders.

THYROGLANDIN.

(EVANS, LESCHER AND WEBB, 60, BARTHOLOMEW CLOSE, .C., AND LIVERPOOL.)

Thyroglandin is stated to be prepared by a patented process in such a way that the active principle is presented for administration instead of the simple thyroid gland itself. It is stated that this preparation is of four times the strength of the fresh glands. The dose is from one to five grains and pills are prepared containing one grain of thyroglandin. Thyroglandin itself is in appearance a brownish powder like dried beef meal and possessing a similar smell. It yielded, we found, an important amount of iodine on suitable treatment and extraction. The preparation is an important addition to organotherapy and is calculated to ensure greater uniformity and certainty of action.

FLORIO'S VIRGIN MARSALA.

(FLORIO AND CO., MARSALA, AND SECRETAN, CAMPBELL AND CO., 24, ROOD-LANE, E.C.)

We have received two specimens of this wine for examination. The difference in composition will be seen in the following analyses which we have made. Marsala marked V.: extractives, 6·03 per cent.; mineral matter, 0·47 per cent.; sugar, 3·60 per cent.; tartaric acid, 0·30 per cent.; acetic acid, 0·15 per cent.; alcohol, by weight 14·82 per cent., by volume 18·25 per cent., equal to proof spirit 31·99 per cent. Marsala marked V.V.O: extractives, 6·43 per cent.; mineral matter, 0·38 per cent.; sugar, 4·16 per cent.; tartaric acid, 0·27 per cent.; acetic acid, 0·078 per cent.;

classes who employ domestic servants have been multiplied and that the classes whence they are drawn have become more independent and have a much wider range of choice in selecting an employment than was the case when manufacturing industries, the Post Office and the Telegraphic Department, clerical work and board schools, did not offer occupation to women on such a large scale as they do at present.

An intelligent study of these conditions will do much to enable families and ladies at the head of families to understand the problem of getting and of keeping good servants. It is well within the experience of medical men that the worry connected with servants and with the constant changes of the domestic staff is a fruitful source of much annoyance and even of ailment among housewives. Ours is a profession which has insight into household work and its cares not vouchsafed to men of other callings. It is not, therefore, beyond our province to give a few hints with a medical bearing which may tend to make the wheels of domestic work revolve more smoothly. One thing which must strike most medical practitioners is a disposition to ignore the ailments of servants. This disposition is seen often at the time when the servant is a mere applicant for work. Mistresses who will keenly inquire into the character or temper of a girl will turn a blind eye on her state of health. Domestic servants are probably not much more subject to ailments than other people but it is an unmistakeable fact that they are not without ailments. Their life is not always a healthy one, though it might often be made more so by a little effort on their own part or good nature on the part of their mistresses. The daily routine is apt to be dull and monotonous and it may be very laborious and exhausting. Those who have only to tell a maid to do things which they can easily do themselves are very apt to abuse the relationship and to throw quite an unreasonable amount of work upon their servants. Such evil is often unintentional. It is wrought by want of thought and not by want of heart. But it is wrought all the same and the life of the servant becomes a drudgery with no leisure, no protection, no break. Servants may not be more delicate than others, but as we have said the conditions under which they work are such as to generate moodiness, perhaps ill-health, and sometimes exhaustion and disease. Besides the conditions of work which tend to generate sickness and even disease there are two other points to be taken into account—age and distance from home. A large proportion of servants, in London especially, are at sensitive ages, and a large number are far away from home; they have come from the country and from p[illegible]cial towns, often from Scotland, and easily become [illegible]ick, especially if there should be a lack of sympathy and a failure to make them feel welcome. One of the commonest of ailments in domestic servants is chlorotic anæmia and it is amazing to see how often this condition is allowed to go on without notice and without treatment where the symptoms in a child of the family would quickly command all the resources of medicine. The neglected chlorosis drifts into chronicity with consequent impaired health or reaches a crisis in a gastric hæmorrhage and so commands attention. Short of such extreme cases the health of servant maids is often sapped in a way which impairs their energy and depresses their spirits, but which would admit of complete relief if duly attended to. These are the servants, by the way, who complain of their food. It is the appetite not the food that is generally at fault, for, despite the behaviour of Mrs. Nicholls and Miss Brass, the modern servant is generally well fed—almost invariably much better fed than she ever could have been in her own home.

It will be asked what is the remedy? We have a strong conviction that the remedy lies in a little more sympathy and a little more effort on the part of families to place themselves in imagination in the servants' situation and to remember that they are of our own flesh and blood, as Mr. GLADSTONE said of the unenfranchised voters. In matters of open air and of hours of leisure servants should be treated with consideration. So far from spoiling them we believe that such consideration is appreciated by them and it certainly is necessary if they are to be kept in health. When servants fall off in health, still more if they become really ill, they should receive attention. If necessary they should be made to keep their bed for a day or more. Devices for sparing them unnecessary labour should, then, be multiplied. The absence of such ingenuity in kind and well-to-do families is often surprising. An anæmic girl will be sent up long flights of stairs on trivial errands, or a willing maid will be made to do nursing duty till her feet swell and she is on the point of breaking down. It is, we believe, no part of a master's liability to provide medical attention for his domestic servants. All the same, or, rather, all the more, it is well to provide it for them. Servants often prefer their own medical man, but few of them are insensible to the kindness of a mistress who will offer her personal attention together with the advice of the medical man whom she consults for her own ailments and those of her children. These may seem to be partial and inadequate suggestions for the solution of a great social problem, but we do not profess to speak except from a medical point of view. We believe that the alternative employments which draw girls from domestic service would not be so effective if good mistresses determined to face the problem and to make their servants feel that they are in a home where their health and their comfort are considered in a kindly and generous spirit.

◆

IN THE LANCET of March 18th we dealt with the action which the Government have decided to take with a view to the prevention of tuberculosis in man in so far as milk is concerned; and whilst we admitted that some progress in this direction would probably result, we expressed our regret that a number of important matters were left untouched by reason of the unwillingness of the Government to ask for any new legislative powers as to tuberculosis. Since the issue of the new Order and Regulations as to Dairies, Cowsheds, &c., a very important deputation has been received by Mr. CHAPLIN and Mr. WALTER LONG, presidents respectively of the Local Government Board and of the Board of Agriculture, and as this deputation raised the same question in so far as it affects our meat supplies. The deputation included

Members of Parliament and a large number of representatives of societies concerned in the sale of meat and of agricultural associations, and it was introduced by Mr. W. FIELD, M.P., who gave evidence before the Royal Commission on Tuberculosis of 1896 in his capacity of President of the National Federation of Butchers and Meat Traders of the Three Kingdoms.

The demands made by the deputation may be dealt with under three headings. Firstly, the butchers and the farmers interested in our meat-supplies asked for uniformity in the system of meat inspection and in the conditions affecting the seizure of meat on account of tuberculosis, and they alleged that in certain towns the stringency in this matter is exceptional, unnecessary, and vexatious. This demand is most reasonable and it can largely be attained by the substitution of public for private slaughter-houses in all large centres of population, by the requirement that meat inspectors shall have some skilled knowledge of their duties, and by the adoption of a code indicating that which ought to be and that which need not be seized in the interests of public health. We shall revert later to the first point. As regards the second Mr. CHAPLIN explained to the deputation that he hoped much from the circular letter which he addressed to district councils when he issued his recent Dairy and Cowshed regulations. In this circular he followed one of the recommendations of the Royal Commission and urged that no inspectors should be appointed for meat-inspection unless possessed of knowledge under three headings which he specified. Unfortunately, the unwillingness to legislate leaves this matter in the position of mere advice which cannot be enforced and we must wait to see how far it will be successful. Much the same applies to the third point, but still the matter is different. The medical officer of health must, after all, be responsible for the action he takes in seizing or not seizing a carcass or a piece of meat from a tuberculous carcass and no legislation can be expected to free him from this responsibility. But subject to this consideration an instruction of advice has now been issued in which, again following the terms of a recommendation of the Royal Commission, Mr. CHAPLIN has indicated what are the conditions of meat which should or should not be deemed to justify seizure. Most medical officers of health when giving evidence before the Royal Commission expressed their willingness to take any such authoritative statement as a guide for their action and we hope that a fair trial will be given to procedures under the new conditions. If this is done then we agree with Mr. CHAPLIN that this grievance will be practically removed.

In the second place the deputation demanded compensation for the value of carcasses seized in the interests of public health. The full bearings of this question of compensation cannot be adequately discussed in this article; it is also one as to which the Royal Commission were not unanimous. The majority, however, decided against this demand and Sir RICHARD THORNE who was one of the majority has set out in his recently published Harben Lectures on the Administrative Control of Tuberculosis the several grounds on which presumably this decision was come to. Mr. CHAPLIN only referred to three reasons which are embodied in the report of the Commission, but he particularly emphasised the fact that our vital statistics, so far as they go, tend to disprove the allegation that the production of tuberculosis through the consumption of meat is a substantial evil, and the still further fact that, although the Commissioners again and again asked for witnesses who could give them evidence of personal loss through seizures for tuberculosis, nearly all the witnesses produced, including Mr FIELD, M.P., had to admit that in a lifetime of active business they had hardly suffered at all. Mr. CHAPLIN naturally assumed that such "weighty objections" to the system of compensation for a trade risk would have been challenged either in the minority report of the Royal Commission or by the deputation, but he found no answer from either one or the other, and hence he was not prepared to lay down the entirely new principle that a purchaser who, having bought an article at a known risk with a view of placing it on sale, "should receive the whole profit of his transaction if he has escaped loss but should demand compensation from the public if his transaction has not been fortunate." He urged, indeed, that the system of insurance such as has already been found to work well and without any burden should be adopted generally. But the deputation had come for compensation and declined, for the moment at least, to entertain this proposal.

In the third place the deputation urged the retention of private slaughter-houses and they went so far as to say they did so in the interests of the public. This attitude must have been aimed, we assume, at getting compensation for any loss that may be incurred under any new legislation, for the reasons alleged in favour of the retention of these private establishments do not bear investigation in so far as public interests are concerned. We have already referred to the provision of public slaughter-houses in another part of this article and we would recall the fact that a number of witnesses before the Royal Commission admitted that the uniformity of administration which this deputation also asked for can only be attained by the substitution of public for private slaughtering places. This is also the view taken by the Royal Commissioners whose recommendations on the subject are most clear and distinct, and we can only hope that the Government will do all they can to facilitate the erection of public slaughter-houses in all large centres of population and thus to secure that the slaughtering shall be controlled and supervised by an efficient staff.

On the whole, we doubt whether the deputation are likely to gain much so long as they take up an attitude which in one important respect is so obviously opposed to public health interests, whilst pleading, on the other hand, that they should receive compensation for action which they allege is taken in the same interests. For the present the prospect of progress in this matter of the prevention of human tuberculosis through the use of meat will mainly depend on compliance with the suggestions contained in the circular letter issued by the Local Government Board. But just as we regretted that no change or progress is proposed as regards the control of our milk-supplies in so far as tuberculosis is concerned (except that which can be effected under the existing defective law), so also we cannot but feel disappointed that in the matter of our meat-supplies the Government also limit themselves to mere advice instead of acquiring new statutory powers to deal with the whole matter in a comprehensive manner.

Annotations.

"Ne quid nimis."

THE PRESIDENCY OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE choice of a President by the Fellows of the Royal College of Physicians of London is a matter which no longer concerns merely the select circle of that body, for the position which the College holds in the medical world, the important part which it plays in conferring diplomas to practise, not to mention its influence in the promotion and maintenance of a high standard of ethics, have given a wide interest to those occasions when a change has to be made in the occupant of the Presidential chair. That such a change is about to take place is no secret. Sir Samuel Wilks, the eminent and highly esteemed physician who has borne the burden of office since he was called to fill the vacancy caused by the illness of the late Sir J. Russell Reynolds, has earned a well-merited retirement after three years' service and will carry with him the sincere thanks and good wishes of the College. When the Comitia meets on March 27th some difficulty may be experienced in arriving at a decision of the question—who shall be elected to fill the Presidential chair? Many physicians have been mentioned as eminently qualified to hold office. Other things being equal, no doubt seniority of standing and past services rendered to the College will have due weight in guiding the choice of the Comitia. Again, owing to the high position which the President of this College holds as the leader of English medicine other reasons than those based on purely professional distinction will no doubt have considerable influence in determining the result of the election. Amongst those who may reasonably be expected to receive support are Dr. F. W. Pavy, F.R.S., who was elected a Fellow in 1861; Dr. W. H. Dickinson, elected in 1865; Sir W. H. Broadbent, F.R.S., elected in 1869; and Dr. W. S. Church, elected in 1870. The scientific attainments and personal attributes of these gentlemen are so well known that we have no doubt that any one of them would discharge the duties of President with ability and discretion. Dr. Pavy's researches in the physiology of digestion, and especially his illuminating work on diabetes, which have been pursued for many years, Dr. Dickinson's pathological investigations and his recent occupancy of the Presidential chair of the Royal Medical and Chirurgical Society, and Sir William Broadbent's contributions to clinical medicine and his enthusiastic support of movements for the furtherance of public health and education will all doubtless be recalled when the choice is about to be made; whilst the services of Dr. Church within the College itself and his intimate acquaintance with its affairs give him a high claim to its chief office. In addition to the above the names of other distinguished Fellows suggest themselves and will doubtless secure support on this occasion, such as those of Sir R. Douglas Powell, Sir Dyce Duckworth, Dr. Gee, Dr. Hughlings Jackson, and Dr. Charlton Bastian.

FOOD POISONING.

THE following case, related by M. Louis Rénon at the meeting of the Société Médicale des Hôpitaux on Feb. 17th, is important as a contribution to the comparatively unknown subject of food poisoning and interesting on account of a very uncommon symptom—arthritis. M. Rénon remarked that various chemical agents—lactic acid, the poisons of uræmia, uric acid, tuberculin, and therapeutical serums—may cause "pseudo-rheumatism." So may food poisoning; in 1760 Boissier de Sauvages wrote: "Fish caught in the island of Bahama excite violent pains in the joints of those who eat them. These pains terminate in a certain time in a sensation of itching which lasts three days." But arthritis from such a cause as exemplified in the following case is not common. A young man, aged 20 years, had a mild attack of influenza; on the third day the temperature was normal and the pains had disappeared. He took at lunch on the fourth day a small portion of chicken, a sole, and a dozen oysters. A few hours afterwards he had a feeling of weight and pain in the abdomen. Urticaria appeared at 6 P.M. and during the night he became covered with large wheals; on the following morning they were retrogressing, but movement of the left arm was painful, and the right hand was œdematous on the dorsal surface, red and painful, and every movement caused him to cry out. The metacarpo-phalangeal joints of the index finger and the little finger were swollen; they were very tender to pressure and to the least movement of extension or flexion. The sheaths of the extensor tendons were equally tender. The wrist presented the same pain on the least movement. Supination, flexion, and extension of the forearm were painful, but the pain was less than in movement of the other joints. There was no fever. The tongue was indicative of dyspepsia and the abdomen was a little tympanitic. There had been constipation for 36 hours. The other organs were normal. "Pseudo-rhematism" due to poison by the oysters or fish was diagnosed. The treatment consisted of milk diet, purgation, and the drinking of large quantities of fluid. On the fourth day of the poisoning the eruption and the œdema of the hand had disappeared. The metacarpo-phalangeal joints and the synovial sheaths were not painful, but the pain persisted in the wrist and elbow. On the sixth day all the symptoms had gone. What was the nature of the articular and tendinous inflammation? Acute rheumatism was excluded in consequence of the absence of fever, the rapid evolution, and the other signs of gastro-intestinal intoxication. Influenza was not the direct cause, because it had lasted scarcely 24 hours, was extremely mild, and had passed off two days previously. Perhaps the influenza had led to slower elimination of the poisons. The gastric symptoms and the urticaria point to the fish or oysters as the cause. Curiously the arthritis developed in the places first attacked by urticaria but it did not recede as rapidly.

THE REGISTRATION OF STILLBIRTHS.

WE have received a copy of a petition to be presented to the House of Commons from the members of the British Institute of Undertakers with regard to the present requirements for the purpose of interment of a stillborn child. The petition shows that at the present time all that is necessary is the production to the cemetery authorities of what purports to be a certificate of the delivery of such stillborn child signed by a medical practitioner or a midwife, no registration with the district registrar being required. It further points out that there can be no ready means of testing the veracity of such certificates, written as they often are on scraps of paper or even in pencil, and yet as a rule they are accepted by most of the cemetery authorities without demur. The British Institute of Undertakers believe, and we can well imagine that such is the case, that the present method of certifying the birth of a stillborn child is open to serious abuses which could be avoided by a proper certificate being issued by a proper authority. We have on several previous occasions drawn attention to this anomalous and dangerous state of things and the whole question was considered by the Select Committee of the House of Commons for the Improvement of Death Registration and Certification. In their report issued in 1893 they stated: "There is reason to think that if statistics upon the subject could be obtained it would be found that the number of children buried in the United Kingdom annually as still-*born is enormous.*" The Committee recommended that stillbirths which had reached the stage of development of seven months should be registered upon the certificate of a registered medical practitioner and that it should not be permitted to bury or otherwise dispose of such a body until an order for burial had been issued by the registrar. This recommendation would apply apparently only to stillbirths of seven months or upwards, but such form but a proportion of the whole number. It is estimated that the total number of stillbirths in England and Wales reaches 45,000 per annum. What percentage of these reached the period of seven months it is impossible to say, but obviously a very large number must be below that age. In the Parliamentary Return issued to the House of Commons in June, 1893, and analysed by us at the time, it was shown that in a large number of countries the registration of stillbirths is compulsory and is carried out by the authorities who register births and deaths. The only remedy for the existing state of things and its possibilities *of serious abuse is the adoption of some such compulsory* system. The difficulties, however, in carrying it out would be very great. At the present time no registered medical practitioner attends at the majority of stillbirths, probably a half or more are attended by midwives, and in a great many cases not even a midwife is present. Who is to certify such cases for registration? Then, again, the difficulty of exactly defining a stillbirth is no light one and in the report referred to the definitions adopted by the different countries are exceedingly numerous and varying. If the duties implied by such legislation are to be carried out by general practitioners or by a public official, such as a medical officer of health, it will mean a great increase of work and responsibility and a corresponding increase in the cost of registration, since it is obvious that some fee would have to be charged for the certificate which in very many of the cases the parents would be unable to pay and it is exceedingly doubtful if Parliament would sanction any scheme involving such a large increase of expenditure. Still, if compulsory notification of stillbirths can be carried out in such countries as Norway, Sweden, Denmark, and Italy, it should certainly be possible in the United Kingdom, and the British Institute of Undertakers have our best wishes for success in their laudable endeavour to promote legislation upon this most important question.

THE IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.

THE St. Patrick's festival dinner of the above association, given at the Café Monico on March 18th, under the presidency of Sir William Thomson, F.R.C.S. Irel., was a very great success. The company numbered about 250. The guests of the evening, who were numerous, will long regard it as one of the best dinners and one of the most brilliant gatherings at which they have been present. The music was good, the speeches were far above the average of after dinner oratory, and the room was graced by the presence of ladies. We have often heard the question of the presence of ladies at such dinners discussed and sundry arguments advanced against it. One thing is certain—that on this occasion they did not hinder any of the ordinary parts of the entertainment. Among the guests were General Sir George White, V.C., G.C.B., G.C.S.I., G.C.I.E.; General Sir Thomas Gordon, K.C.I.E., C.B.; and Sir Dennis Fitzpatrick, K.C.S.I. The medical profession was well represented by Sir William MacCormac, Bart., K.C.V.O., President of the Royal College of Surgeons of England; Inspector-General William Lloyd, R.N.; Sir William Gowers, Professor Alexander Macalister, F.R.S., and others. Sir William MacCormac, in proposing the health of the guests and alluding specially to the guest of the evening—Sir *George White*—spoke in high terms of the Indian army as one of the most important armies in the world, ready for anything and for any emergency. The acts of devotion and the feats of daring which it performed came to us muffled by the distance of the far off fastnesses in which they were performed and by the absence of reporters of sensational incidents. But India had been the scene of our greatest triumphs not only in arms but in government, and the humanity and consideration of our rule had won the respect of the various races which owned our authority. Professor Alexander Macalister proposed "Our Defenders" and did so with his usual grace of speech and fund of illustration. The toast was responded to by Sir Thomas Gordon in an admirable speech in which he paid a high tribute to the medical element in the services. It is no disparagement to other speakers to say that the speech of the evening was that of Sir George White who spoke like a soldier who has played a great part in a great field of labour and responsibility, and he followed the example of Sir Thomas Gordon in eulogising the medical care of the sick, especially after the late operations on the North-west Frontier, where the wounded had to be conveyed for 100 miles under great disadvantages alike of climate and carriage and yet showed a high average of recoveries. We congratulate the association on the success of their festival dinner. Previously to the dinner the annual meeting was held when the report for the year 1898-1899 was read *The Council congratulated the association upon the good work done during* the year, especially with regard to the desirable reforms asked for in the position of the Irish Poor-law medical officers. The association had a balance of over £96. After the election of sundry gentlemen as new members and the usual votes of thanks the meeting terminated.

RETROBULBAR NEURITIS.

THE February number of the *American Journal of the Medical Sciences* contains an article by Dr. William Sym of Edinburgh on the imperfectly studied subject of Retrobulbar Neuritis. The term was introduced by von Graefe to indicate optic neuritis arising primarily in the nerve or by continuity *with other parts,* and *not from intracranial* pressure. As in some cases there were no ophthalmoscopic changes the lesion was referred to a portion of the nerve behind the eye. According to Mr. Gunn, "rapid failure of vision, usually in one eye only, often accompanied by pain and tenderness in the neighbourhood, absence of *early ophthalmoscopic* changes, and a tendency to recovery, are the usual prominent features." The *failure of vision* is of a peculiar type; it is principally or solely central; *its degree* varies from a loss of definition to complete loss of light perception. In the less severe cases there is central loss of colour perception; blue and yellow may be fairly correctly seen whilst red and green are lost and appear as yellow and white respectively. In bad cases there is central loss of all colour perception. Many patients say that whilst vision is bad in the bright hours of the day it improves in the evening. It is not probable that there is improvement in visual acuity though the patients see better in the subdued light, possibly on account of exhaustion by the brighter light of the affected fibres. Vision is better after a night's rest but worse on fatigue or fasting. The patient is apt to complain of a fog or mist before the eye. A symptom present in a considerable proportion of cases of ordinary neuritis and first described by Dr. Hughlings Jackson—temporary, almost momentary, attacks of blindness—is never found. As to the description of retrobulbar neuritis as usually unilateral Dr. Sym thinks that its truth depends on whether toxic amblyopias are regarded as a variety. Apart from this, retrobulbar neuritis not infrequently affects both eyes consecutively. Ophthalmoscopic signs are usually absent early and may be, but are not usually, absent altogether. But they are trifling in proportion to the loss of vision in contrast to ordinary optic neuritis where the ophthalmoscopic signs may be great and visual symptoms absent. The prognosis usually is good; improvement is to be expected in a few weeks or even days, which sometimes coincides with the appearance of ophthalmoscopic signs, so that curiously sight is improving whilst the signs are getting worse. In a large proportion recovery seems to be complete, but in some a decided and perhaps an absolute scotoma remains permanently. The unilateral cases may be due to the spread to the nerve of local inflammation, or to syphilis, rheumatism, gout, or malaria. They do not differ essentially from the bilateral except in the tendency to recovery. The latter occur in diseases of the spinal cord, especially locomotor ataxia, disseminated sclerosis, and general paralysis of the insane; they include hereditary optic atrophy and toxic amblyopias. The treatment of the unilateral cases consists in attacking vigorously the constitutional cause—in rheumatic cases by purging, salicylates, and blistering the temple. Action of the skin and kidneys must be encouraged. Pilocarpine subcutaneously will be found as useful as in persistent scleritis. Some believe in iodide of potassium and mercury even in non-syphilitic cases. In the longer-standing cases, especially those more nearly allied to atrophy, strychnine is chiefly relied upon, but it has little influence.

THE LIVERPOOL MEDICAL INSTITUTION.

AN interesting ceremony took place at the Liverpool Medical Institution on March 15th, when Dr. John Cameron, the senior physician to the Liverpool Royal Southern Hospital, was presented with a congratulatory address upon his attaining the sixtieth year of his membership of the society. The occasion was looked forward to with much interest by the members and associates, as Dr. Cameron's connexion with the society had extended over a period which had not been reached by any of his predecessors or compeers. At the invitation of the President (Dr. W. Macfie Campbell) and the Council, a large number of members and associates attended to do honour to their veteran colleague who on the auspicious occasion happily appeared to be in robust health. The address, which was handsomely illuminated, was read by Dr. John Birkbeck Nevins, the member of the society next in point of seniority, and was in the following terms:—"To John Cameron, M.D., F.R.C.P. The members of the Liverpool Medical Institution desire to congratulate you on attaining the sixtieth year of your connexion with the society. We wish to thank you for your long services as trustee, councillor, and as president in 1872, when you worthily upheld the dignity of the chair and of the profession. As physician to the Royal Southern Hospital for a long series of years you have shown enthusiastic and unwearied devotion to clinical work and to the good of the charity. As head of the consulting branch of the profession your conduct has always been marked by a high sense of honour and courtesy to your medical brethren. We wish you many years of useful life in our midst, and we take the opportunity of this anniversary to assure you of the esteem and regard of your fellow members, to whom your career will always remain a conspicuous example of professional integrity." The address was signed on behalf of the members by W. Macfie Campbell (the President), John M. Hunt (honorary general secretary), and William Thelwall Thomas (honorary secretary of ordinary meetings). Dr. Nevins said that among his early recollections of the institution in which Dr. Cameron took a leading part the society at first met in an upper room. It was not an uncommon experience for the meetings to be postponed in consequence of the necessary quorum of seven members not being present. In 1848 the average of attendances at the ordinary meetings was 14, whereas now the average is 80. Dr. Nevins eulogised the marked industry which characterised Dr. Cameron during a long life and urged the junior members to follow his example. Mr. Edgar A. Browne spoke on behalf of the ordinary members and said that the occasion was a red-letter day in Dr. Cameron's life and in the history of the Liverpool Medical Institution. Such an occasion was probably unique in the history of any society in having an active member for such a long period as 60 years; but Dr. Cameron came from a race of men of strong natural fibre and his honourable life is an example to be followed. Dr. William Permewan made further congratulatory remarks on behalf of the junior members of the society. Dr. Cameron, in his reply, expressed his grateful thanks for the honour conferred upon him, which he accepted as a mark of personal regard. He described the early struggles of the society and paid a generous tribute to its founders of the year 1837. It was now in a condition of prosperity, possessing upwards of 300 members and associates, and he personally had derived great benefit from his membership. The presentation of the address was preceded by a conversazione which was numerously attended.

THE LATE LORD HERSCHELL AND THE JENNER SOCIETY.

AT a recent meeting of the Jenner Society held at Gloucester it was unanimously resolved to send to Lady Herschell the following expression of appreciation of the great service rendered to his country by the late Lord Herschell as President of the Royal Commission on Vaccination:—

> "The President and members of the Jenner Society, whilst uniting in the general expression of deep regret for the death of the late Lord Herschell and of warm appreciation of the great services he in so many ways rendered to his country, desire especially to record their high sense of the singular ability, the perfect impartiality, and the untiring patience with which, as President of the Royal Commission on Vaccination, he for seven years conducted an important and difficult inquiry, with the firm determination, as he himself subsequently said, 'to follow boldly the facts which experience disclosed, whithersoever these might lead,' and with the earnest desire, when the truth had been established, to so apply it as might be most beneficial to the public health."

The resolution is signed by the President (the Earl of Ducie, Lord-Lieutenant of Gloucestershire), the Chairman of the Executive Committee (Dean Spence, D.D.), Mr. G. E. Lloyd Baker (High Sheriff of Gloucestershire), and Dr. Bond (the honorary secretary).

VACCINATION CERTIFICATION IN SCOTLAND.

A TRIAL has recently taken place at Inverness in which a medical man, Mr. John Lamont, was charged with having issued false certificates of successful vaccination during the time that he was medical officer of the parish of South Uist, between August, 1897, and July, 1898. As a matter of fact Mr. Lamont's custom was to vaccinate children and then rely upon a statement of success from the parents, a minister, or a schoolmaster. On receiving this he signed the form for successful vaccination. Various other practitioners in Inverness stated that they did the same thing. This, however, does not make the practice right. As a matter of fact, no one man could possibly undertake the duties of a Highland island district with any real chance of doing the work properly. It is beyond human capabilities to do so. Mr. Lamont worked heroically through an epidemic of typhus fever and won commendations from the Local Government Board for his heroism. Not only did he visit the sick, but he nursed them and even when they died put their bodies into the coffins because no one else would do so. He does not seem to have got on with the parish council and was dismissed in July, 1898, by that body. In the following September he was arrested on the charges mentioned above. He was apparently ignorant of the rules laid down by the Local Government Board, for the parish council had never sent him a copy. And as a matter of fact, although 16 certificates were said to be wrong it did not come out in evidence that they all were so. The jury unanimously brought in a verdict of "Not guilty" and allowed Mr. Lamont's expenses.

CRIME AND THE RESPONSIBILITY OF THE PRESS.

WHEN a crime is chronicled in a certain section of the press in such a manner as to minister to the taste of morbid sensationalism it is safe to predict that within a few weeks or possibly a few days only the world will hear of another crime whose details correspond with the accounts of the previous one. Recently the news was received from America that two members of a well-known New York club had received through the post a bottle purporting to contain medicine but which really contained a salt of mercury, the object being to poison the recipients. Two deaths resulted. Now we hear that an inmate of Leavesden Pauper Lunatic Asylum has met with her death in a similar manner. In this case, however, the drug was sent in a parcel of cake. A forged letter written by an illiterate person was received by the deceased before her death. That the second crime is an imitation of the first one is highly probable. The idea of sending poisons through the post is a novel one and it is unlikely that an ill-educated person would conceive it without having some example before him and in this case there can be little doubt that the example was that of the Knickerbocker Club crime, accounts of which have been copied into English journals. That section of the press, especially of the American press, which seizes upon stories of crime and paints them with all the icteritia of which the "yellow" reporter is capable must certainly be held responsible for a great amount of harm. It is well within the reach of possibility that weak-minded people who perhaps have often thought of committing a crime but who have not had the courage or the wit to put their thoughts into practical effect should be stimulated by sensational accounts of successful criminal exploits to do that which otherwise would have remained a creature of their imagination. It is the old story—

> "How oft the sight of means to do ill deeds
> Makes ill deeds done."

HISTOLOGY OF THE SKIN.

IN the second number of the *Comptes Rendus* for 1899 M. Ranvier gives the results of his long-continued microscopical observation of the structure of the skin in man and in the lower animals. The succession of layers of the epidermis as now generally admitted is the stratum corneum or external or superficial desquamating layer, the stratum lucidum, the granular layer, the Malpighian layer, and deepest of all, resting on the dermis, the basilar generating or germinal layer (stratum germinativum), so-called because when uninjured the other layers of the epidermis can be derived from it. According to M. Ranvier the layer that is just beneath the stratum granulosum of Langerhans—that is, the Malpighian layer—is characterised by the presence of numerous fibrils embedded in the cell protoplasm and he has therefore named it the stratum filamentosum. The filaments are not affected by water even when boiling; they swell in acids and in alkalies and become coloured violet with hæmatoxylin and red with carmine. With thionine they assume a pale green tint or remain uncoloured, though this renders the cell protoplasm of an intense violet colour. The filaments are not therefore simply processes of protoplasm. They are doubly refracting. Like the granules of eleidine in the stratum granulosum or like starch grains they are products of cell activity. In regard to the stratum lucidum of Oehl and Schroen, M. Ranvier finds that it is in reality double. To demonstrate this sections of skin made after immersion for an hour in osmic acid, then for 24 hours in alcohol, are coloured with picrocarminate and examined in glycerine. The eleidine is not coloured because it has undergone osmic metallisation. The true stratum lucidum is not coloured either by the carmine or by the osmic acid, but immediately beneath it and above the stratum granulosum is a thin layer which assumes a bright-red colour. It is composed of only two or three layers of transparent cells. Its external surface is smooth, the internal is festooned. It is this layer which in M. Ranvier's opinion really separates the two chief layers of the skin, the only ones formerly admitted—viz., the corneal layer and the Malpighian layer. M. Ranvier names it the stratum intermedium. It is remarkable that although it colours so deeply with carmine it does not colour at all with purpurine. After hardening in alcohol it remains uncoloured with thionine whilst this stain colours the stratum corneum verum green and the stratum filamentosum violet. The nuclei of the cells of the stratum intermedium are atrophied and their investing membranes present epidermic fibrils which are wound like the threads in a cocoon. According to M. Ranvier, then, no less than seven distinct layers can be demonstrated by the aid of staining agents to be present in the epidermis. These are named, beginning with the deepest which is in contact with the dermis, the stratum germinativum, stratum filamentosum, stratum granulosum, stratum intermedium, stratum lucidum, stratum corneum, and stratum disjunctum, which last is formed by the superficial desquamating cells.

CONDENSED SEPARATED MILKS AND FALSE DESCRIPTIONS.

ON March 20th Mr. Walter Long, the President of the Board of Agriculture, received a deputation upon the subject of the Sale of Food and Drugs Bill. The deputation consisted of representatives from various provincial and metropolitan local authorities and their object was to ask for the insertion of a clause in the Bill making it obligatory for manufacturers to label tins of condensed, separated, or skimmed milk so as to indicate that it was not fit food for children or invalids. The deputation was introduced by Mr. Radcliffe Cousins, chairman of the Camberwell Vestry. Mr. W. W. Stocker of Willesden said that in a period of four weeks infant mortality in Willesden had reached 40 per cent. chiefly through deaths from diarrhœa caused by bad feeding. He considered condensed separated milk useless for infants' food. Mr. Cassall, the public analyst of Kensington, gave evidence as to the poverty of some condensed milk. Mr. Long said that if the public liked to buy a thing they must be allowed to buy it. The Government could not put shackles on the public for this purpose. The safest line for the public and the Government was that the public should know what they were buying. We quite agree with this last remark, but will the Government take steps to ensure this very desirable result?

Will they, for instance, make it obligatory for those who sell mixtures of chicory and coffee not only to label the tin or packet to the effect that it contains a mixture of chicory and coffee but to state the exact proportions of each? Likewise upon the fabric known as "union" the exact proportions of linen and cotton should be stamped. It is keeping knowledge from the purchaser to sell such fabric either as linen or cotton, for it is neither wholly one nor the other; and so with very many other articles, such as ivorine, leatherette, amberoid, and the like. Every article made of celluloid should be marked in some way to tell the purchaser that it is inflammable, especially in the case of celluloid cigarette-holders; or, still better, the sale of these last should be prohibited. With all due respect to Mr. Long, the essence of a Government is to put shackles on the public. The Sale of Food and Drugs Bill as it stands at present is wrong and unsound and we earnestly hope that the Grand Committee will amend it thoroughly or else that it will be thrown out.

THE FATAL CASE AT BALLINCOLLIG BARRACKS.

WE cannot feel surprised that the deplorable circumstances attending the death of a young soldier of the 17th Lancers whilst undergoing confinement in a prison cell at Ballincollig Barracks, near Cork, were made the subject of earnest inquiry and debate in the House of Commons on March 17th. Mr. MacNeill, who introduced the matter, spoke in indignant terms about the punishment system of the army generally and particularly of the treatment which had been dealt out to the trooper in question. Mr. Wyndham replied in sympathetic terms and expressed his regret at the loss of a young soldier so soon after his entering the service, but he said that the most searching inquiry had been made into the case and he then proceeded to detail the facts connected with the occurrence. We may say at once that, so far as Major Fortescue, the officer commanding, and the military officers were personally concerned they seem to have acted with proper care and discretion, and it appeared to be generally admitted that they were quite blameless. With regard to the acting medical officer—for it was a civilian practitioner who was in medical charge of the troops and responsible for reporting as to the health or otherwise of the soldiers in question—the same unanimity of opinion did not apparently prevail. Notwithstanding the attention which was given to the subject in the House of Commons we are somewhat in doubt, however, as to what was the exact nature of the complaint from which the soldier was alleged to have been suffering. The immediate cause of death as determined by the post-mortem examination is stated to have been cardiac thrombosis, but we are not told whether there was any pre-existing valvular disease of the heart, such as might have been reasonably expected to have been discoverable on medical examination. The fact of the poor young fellow having suddenly died showed that he was not at the time in a fit condition to undertake shot drill or indeed to undergo any punishment; on the contrary, the hospital would probably have been the proper place for him under the circumstances. But without knowing more of the detailed medical history of the case than we do we cannot say, of course, whether there was any error in diagnosis attributable to defective medical examination or not. Mr. Wyndham did not admit the existence of anything blameable in this respect, whereas Mr. Carson apparently thought otherwise and that the matter was one for further examination. On the general question as to the employment of civil practitioners in the case of a small number of troops Sir H. Campbell-Bannerman made some sensible remarks and with reference to the unfortunate case under discussion he particularly urged that if the examining surgeon had been a military medical officer, accustomed to see cases of malingering, it might have been said that he took a harsh view, whereas in this case the soldier could have laboured under no such disadvantage for a civil practitioner would be perfectly unbiased. There is only one thing connected with this unhappy occurrence which forms a legitimate subject of congratulation and that is the assurance of the Under-Secretary for War that a large reform in the treatment of military prisoners is under consideration. The whole subject, as it seems to us, of army crime and its punishment requires to be thoroughly reconsidered and revised at the present time.

LEGAL ASPECTS OF CHRISTIAN SCIENCE.

IN the *North American Review* for March an article by Mr. W. A. Purrington is devoted to Christian Science and its Legal Aspects. It is of interest because, apart from considering the possibility of dealing with the so-called Christian Scientists under the criminal law, it gives enough quotations from the works of the enterprising lady who founded the sect to enable those who care to do so to obtain a bird's-eye view of its absurdities. "Christian Science" has hardly as yet made sufficient headway in London to earn the distinction of an article to itself in a leading monthly magazine and beyond its not very numerous fashionable converts and the more curious of their friends its existence was hardly appreciated until the recent deaths of two gentlemen, one being a prominent journalist and novelist, for a time compelled public attention to the new Act. The legal proceedings which followed the death of Mr. Harold Frederic proved that it will only be in rare cases that persons allowing those immediately connected with them to die in the hands of Christian Scientists without medical aid will become liable to conviction for manslaughter and the "healers," as the persons who let *Mr.* Frederic die are called, seem likely to enjoy equal immunity. This is because the "healers," in this country *at all events*, prudently refrain from undertaking the cases of children who are, fortunately for themselves, protected in some measure by statute. We grant that the Act of Paliament does not prevent the Peculiar People from letting their children die with comparative impunity, but then these persons have always impressed the judges who have tried them with the genuineness of their religious motives. In addition, however, to the more serious penalties attaching where death supervenes there is always in the case of quacks the possibility of a disappointed dupe prosecuting for the obtaining of money by false pretences, or, dupes being always slow to proclaim their folly, of those persons to whom the protection of the public is entrusted prosecuting for the attempt. Should any such measure be resorted to against the Christian Scientists their published documents would seem to supply the necessary material. Like so many of their fellows they find it profitable to print details of so-called "cures"—those cited by Mr. Purrington including a child (in America, no doubt, where they still attend children) who on being lifted from his cradle and kissed was at once cured of inflammation of the bowels, and a lady who was relieved of heart disease and dropsy upon the founder of the sect receiving a letter from the patient's husband. But the police, who are ever ready to attack the gipsy who makes half-a-crown by the venerable and comparatively *harmless* fraud of telling a servant-girl's fortune, stand by and permit abortionists and quacks of all kinds to openly advertise their wares with quite as absurd "cures" to support them and seem hardly likely to interpose at present, while Christian Scientists are no doubt wary enough to keep outside the narrow confines of our Medical Acts and to avoid such dangers as may be run by those not notifying the presence of infectious disease. On the whole, then, allowing for slight differences in our law, we agree with Mr. Parrington that these persons not infrequently offend against the criminal law, and that their prosecution, though not very likely to take place, is desirable owing to the enlightening effect it would have on the public. As he aptly observes in conclusion, "publicity will destroy the cult far more quickly than legislation." Legislation certainly seems superfluous if the existing law be adequate and if it be adequately enforced.

THE EVILS OF SNOW.

A MORE or less heavy fall of snow is not without its effects upon the public health in an unfavourable direction, due in general to an augmentation of respiratory diseases In towns a fall of snow is particularly disagreeable since it soon settles down on the pavements of our streets and in the roadway into a highly chilling muddy slush. It is the readiness and eagerness with which slush absorbs heat in the act of liquefying which renders it so dangerous to the health of those who are obliged to walk through it. Again, it is a notorious fact that however proof a leather boot may be against rain it seldom proves a barrier against the percolation of water derived from the melting of snow. This is probably due to the effect of the intense cold of snow making the leather, so to speak, crisp instead of supple owing to the oil in the leather which makes it supple becoming congealed. In this way probably leather loses its most valuable quality. A useful precaution is to grease the boot outside with an oil of comparatively low melting-point as, for example, goose grease or some mineral oil. A fall of snow, however, is not without some compensatory advantages. It rapidly clarifies and purifies the air. An analysis of snow shows the presence of an enormous proportion of organic impurities and bacteria which are swept out of the air by the descending particles. Again, the friction of snowflakes with the air gives rise to the formation of ozone. The smell of ozone in the air after a snowfall is very marked. We are pleased to note that our vestry authorities on the occasion of a moderately heavy fall of snow in London last Tuesday were on the alert to remove the horrible slush as it accumulated. The City streets were scrupulously clean within a few minutes of the cessation of the fall. This is as it should be, for the presence of a wet freezing mixture in our streets is a source of extreme discomfort and danger to pedestrians.

SANITATION IN HOTELS.

THERE is a praiseworthy tendency at the present time to devote especial attention in a sanitary sense to all places where the public aggregate, and perhaps the best example of this tendency is to be found in the regard which is now being paid to the conditions under which children at ages susceptible to infectious disease are gathered together in our public elementary schools. It is, however, important that we should not in our zeal for the health of the little ones altogether overlook the conditions under which a not inconsiderable number of adults at the bread-winning ages spend a great part of their existence. In the hotels of our great and small towns men in the prime of life and having families dependent upon them are nightly housed under conditions which are often far from satisfactory. The ventilation of their bedrooms, especially in the older hotels, is often highly defective and the other sanitary arrangements are liable to be if not altogether primitive in principle, approximately so in practice. The so called water-closet often may be found ventilating only into an inside passage, itself close and stuffy, while the pan of the closet is old-fashioned in type and the water-supply is *nil.* Furthermore, the pungent odour which arises when the handle of these old-fashioned closets is manipulated bears evidence to the fact that the soil-pipe is imperfectly (if at all) ventilated and that the "container" is coated with filth. Often, too, in this same closet is a defectively trapped lavatory basin which yields a highly offensive smell. It is under conditions such as these that opportunities are afforded for contracting disease, opportunities which are much accentuated by the fact that the lighting of these closets is often extremely defective and hence cleanliness is all but an impossibility. It is difficult to understand why *more attention is not devoted to this matter* by the officers of local sanitary authorities. A periodical visit would do much to bring about a better state of affairs.

IRISH POOR-LAW MEDICAL SERVICE.

ON March 16th a deputation nominated by a public meeting recently held in the Royal College of Surgeons in Ireland was received by the Local Government Board. Sir Thornley Stoker who introduced the deputation said that they came on behalf of the Irish Poor-law medical officers backed by the authority of the largest meeting of the Irish medical profession that had ever been held in Ireland. They only wanted reasonable reforms and by far the most important was the question of superannuation. Dr. J. W. Moore referred to the necessity of allowing travelling expenses. Sir William Thomson referred to the abuse of visiting tickets which were given out without any care. He mentioned one case in which a dispensary medical officer who was summoned on an urgency ticket travelled 10 miles and was shown a pig as his patient. Another medical man was summoned on one occasion to see a cow by a ticket filled in by the owner. On another occasion he had to go out to see a donkey. In this case the chairman of the committee signed the ticket. The Vice-President gave the usual official reply that the Local Government Board would give the matter every consideration. We hope that they will not only consider the question but see that the lot of the Irish dispensary medical officer is made less hard; but we are glad to see that the Local Government Board have intimated to the Cork Board of Guardians that Poor-law medical officers are to have a month's holiday and that substitutes are to be paid by the guardians. We would refer our readers to our issues of Jan. 7th, 14th, and 28th, in which we gave an account of the many hardships under which these practitioners labour.

PATHOLOGICAL CHANGES IN THE NERVOUS SYSTEM IN DELIRIUM TREMENS.

IT is not often that cases of delirium tremens end in a fatal issue if occurring in otherwise healthy subjects free from cardiac, arterial, pulmonary, and renal disease. Uncomplicated fatal cases are rare, and till recently have not been minutely investigated as regards the microscopic and pathological changes which take place in the brain and which render these patients restless, terrified, and subjected to visual and horrifying hallucinations and insomnia, and produce general muscular weakness and tremor of the hands, lips, tongue, &c. Two such cases recently investigated and published by Dr. Ewing[1] of Columbia University (New York) are noteworthy. In one the patient was a young man, aged 25 years, who drank heavily and who was in a state of intoxication for six weeks, finally dying from delirium tremens with exhaustion and pyrexia; the temperature rose to 104° F. before death. In the other case, a man, aged 29 years, from similar indulgence extending over three months (12 weeks), during the whole of which period he was said not to have been sober, also died from delirium tremens, the temperature before death rising as high as 105°. Post-mortem examinations were made soon after death—in six hours in one case and in twelve hours in the other. Intense and general capillary congestion was found in the brains of both subjects. Sections of the brain, medulla, and spinal cord which were made after hardening in Lang's fluid and were stained with Nissl's methylene-blue method gave very striking and instructive changes. To begin with, the great "motor" cells of the cord and medulla were extensively affected and were nowhere normal. The "chromatic rods"—the normal stored-up pabulum of the nerve cell which is used up during functional activity—were almost entirely disintegrated and destroyed or absent in these cells. In many other cells this "chromatolysis" was even more advanced and the cell body showed transparent areas (hyaline degeneration). Further, the outlines of many cells were irregular and ragged (erosion of surface) and the nuclei were dislocated from their normal position, sometimes so markedly as to project from the side of the cell body. Similar chromatolytic changes but to a less extent were found in the cerebellum (Purkinje's cells). In the hemispheres the cortical pyramids (archyochromes) failed to exhibit the usual network or striated arrangement of these rods, and those which were present were either feebly-coloured and indistinct or broken up into coarse granules. In the second patient (three months' intoxication) these changes were more marked. Dr. Ewing compares these changes in delirium tremens with those of acute experimental alcoholic poisoning in animals and decides that the former changes are more marked. The nervous symptoms of delirium tremens are ascribed in large measure to the profound nutritive changes (as revealed above) which alcohol produces and which give rise to restlessness, tremor, insomnia, and pyrexia before they end in a fatal issue. The investigation of cerebral changes in sub-acute and chronic alcoholism described by Andriezen in this country (with the use of Golgi's and Nissl's methods)[2] and by Berkley in America (with the same methods),[3] combined with Dr. Ewing's present research, must serve to show the importance of this branch of neurological investigation and to encourage further work in this direction as regards the cerebral pathology of alcoholism.

[1] Archives of Neurology and Psycho-pathology, vol. i., No. 3 (pp 313-5), 1898.

THE spring meeting of the Northern and Midland Division of the Medico-Psychological Association will be held at the County Asylum, Hatton, near Warwick, on April 12th. Members intending to be present should communicate with Dr. Crochley Clapham, The Grange, near Rotherham.

AT a meeting of the Cremation Society held at Grosvenor House on March 15th Sir Henry Thompson, the President, delivered an address upon the career of the society from its inception to the present time.

H.R.H. THE DUKE OF CAMBRIDGE will preside at the annual dinner of the Sanitary Institute to be held at the Whitehall Rooms on May 2nd.

THE sittings of the Royal Commission on the Water-supply of London came to an end on Thursday, March 23rd.

MEDICAL MAGISTRATE. — Mr. Edmund West Symes, M.D. Edin., M.R.C.S. Eng., of Halifax, Yorkshire, has been appointed a magistrate for that borough.

THE USE OF PHOSPHORUS IN THE MANUFACTURE OF LUCIFER MATCHES.

NOW that the scientific, technical, medical, and dental aspect of the question in regard to the liabilities of those engaged in the manufacture of phosphorus matches has been clearly brought forward we may shortly expect some fresh legislation on this important subject. The names of Professor T. E. Thorpe, LL.D., F.R.S., the principal chemist of the Government Laboratory, Professor Thomas Oliver, M.D. Glasg., F.R.C.P. Lond., physician to the Royal Infirmary, Newcastle-upon-Tyne, and Dr. George Cunningham, M.A. Cantab., senior dental surgeon to the London Hospital, form a trio of authorities whose views and account of the various sections of the subject will carry very great weight and ultimately materially help in the elucidation of a problem which affects the life and well-being of those engaged in the important industry of match manufacture. The Blue Book just issued, which embodies the several reports of these experts and to which an introductory memorandum by the Chief Inspector of Factories, Dr. Whitelegge, has been added, is a valuable contribution to the subject and one which should leave little doubt as to the direction in which the manufacture of matches can be better regulated with a view to minimising the risks of injury to health of the operatives concerned.

We may deal with Professor Thorpe's report first. At the outset he points out the different properties of yellow and red phosphorus and explains that the products of the oxidisation of yellow phosphorus are phosphorous oxide and phosphoric oxide. Only the yellow phosphorus oxidises at the ordinary temperature of the atmosphere. The glow is invariably accompanied by, and is probably dependent upon, the formation of ozone. By the way, we should like to ask whether the ozone which must be produced in comparatively larger quantities in match works has any unfavourable influence on the health of the operatives. This point is not touched upon in the report, although ozone, we believe, has distinctly poisonous properties when inspired in tolerable quantity. In some recent experiments made in the Government Laboratory it was shown that the spontaneous oxidation of phosphorus could be instantly checked by allowing to evaporate about one centigramme of turpentine into 1000 cubic centimetres of air. Phosphorus placed in this atmosphere did not fume or glow nor was any oxygen absorbed. It is suggested, therefore, that the air in the match works might be impregnated with a small quantity of oil of turpentine with distinct advantages. Professor Thorpe also conducted some experiments as to the chemical effect of phosphorus fumes upon the teeth, with the result that a marked solvent action was shown to take place upon the teeth to the extent in the case of a dilute solution of phosphoric acid of a loss of 8·9 per cent. of their original weight. The amount of phosphorus fume in the air of the dipping-room was found to be equal to 0·02 milligramme per 100 litres. In the air of the boxing-rooms it was 0·12 milligramme phosphorus per 100 litres. This increase is due to the firing of the matches. The amount of phosphorus on the average removed on washing the hands was equal to 4 2 milligrammes per head per day of 10 hours. Professor Thorpe follows these experiments with a very interesting account of the match-works in the United Kingdom and the processes carried on therein, while a very exhaustive description is given also of the continental match-works and the special regulations in force in them. From the experience which he has gained in this inquiry he ventures the opinion that in the event of making any amendment of the existing special rules which may be thought desirable the examples of the regulations described in the report will supply all that is necessary upon which to base them, for it has been conclusively established, he adds, that where such rules are vigorously enforced phosphorus necrosis has almost entirely disappeared. As to a substitute for phosphorus, he concludes that a satisfactory one has not yet been found and no method of employing red phosphorus on the match head has been found to be commercially practicable in the production of a "strike anywhere" match. The evils attending the use of ordinary phosphorus can be greatly minimised by observing certain rules in regard to the medical and dental supervision and improving the conditions of environment.

With these conclusions the report of Dr. Oliver practically agrees and he has also had the opportunity of watching the processes of match manufacture as carried out in a number of works abroad. His verdict is summed up in the following sentence: "Under the circumstances, therefore, of experience having shown that methods of manufacture exist which are capable of practically excluding phosphorus necrosis from the industry, of the 'new strike anywhere' sesqui-sulphide match of the French Government still passing through its period of probation, and inventors busy at work, it is premature to recommend the total abolition of white phosphorus in Great Britain and Ireland." Dr. Oliver then epitomises a series of recommendations to be observed in order to avoid the toxic and destructive action of phosphorus fumes upon match-workers.

Dr. Cunningham's report is a very able and exhaustive piece of work dealing chiefly with the origin of phosphorus necrosis. The chief point of his inquiries is that he finds that in the absence of special arrangements for regular dental supervision the teeth are deplorably bad, a condition fostering necrosis of the jaw. According to Mr. Morton Smale phosphorus necrosis can only originate under the following circumstances: (1) when dental caries has exposed the pulp of a tooth; (2) during the healing process after tooth extraction; and (3) during the time there is some lesion of the gum. Like the previous observers Dr. Cunningham does not consider that the yellow phosphorus match trade presents any exceptional dangers which cannot be met by proper precaution, nor does he think that any case has been made out for the prohibition of yellow phosphorus. He recommends that certain special rules affecting the trade should be strengthened. These recommendations turn on a medical and dental examination of all persons engaged in the industries, of keeping a record of this examination as well as of a systematic periodical examination, on proper provision being made for preventing persons from working whose teeth are defective, and, finally, the provision of a supply of mouth-wash for the systematic use of the work-people. Dr. Cunningham's experience of a number of "strike anywhere" matches made without white or yellow phosphorus is that their use in commerce is not as yet practicable, while accidents of some severity have already occurred to those engaged in handling them even in small quantities.

These reports occupy a Blue Book of 236 pages which is very usefully illustrated, the subjects being the various machinery employed in manufacture, the position of the operative in relation to the phosphorus compound, the means of drawing away the fumes by an air exhaust, &c., while in Dr. Cunningham's contribution some excellent diagrams are given showing the condition of caries in teeth and of the nature of the disintegrating action of necrosis following the action of phosphorus fumes on decayed teeth. Our knowledge of the subject is decidedly enriched by the labours of these gentlemen, and the Government have now an opportunity of so regulating the manufacture of lucifer matches as to place the great number of workers in this important industry under conditions entirely free from reproach; for the import of the combined labours of these able investigators on the subject is that there need be no phosphorus necrosis where due care is taken and where regulations are strictly, yet not vexatiously, enforced.

QUACKS AND ABORTION:

A CRITICAL AND ANALYTICAL INQUIRY.

VIII.[1]

DURING the past few weeks the attention of many not usually interested in such matters has been directed to a murder in a house near Tottenham-court-road owing to the fact that the woman believed to have been the victim has now been arrested abroad and is likely to be charged with the commission of the crime. It will apparently be suggested against her that the murdered woman died in consequence of an illegal operation and that she and those who performed it were brought into communication by means of an advertisement in a German newspaper published in London—the *Londoner General-Anzeiger.* We call attention to the advertisement because whatever bearing it may or may not have on the case in question, and whatever may be the degree of guilt or innocence of the woman under arrest, it is an advertisement akin to those against the unchecked publication of which we are protesting. Headed "Private Confinement," it offers, accompanied with secrecy, advice and help in women's troubles, while other similar advertisements accompany it in the columns in which it appears. Further comment at the present stage would be out of place.

Privat-Entbindung.

Diskret. Rat und Hilfe in Frauenleiden erteilt Frau Briesenick, 8 Whitfield Street, Tottenham Court Road

---

We give below a second list of newspapers published in Great Britain and Ireland which have during the past few weeks contained advertisements of persons who profess more or less openly to sell abortifacients, or whose goods are liable to be bought by ignorant women seeking to put an end to their pregnancy owing to their claiming to "cure all obstructions" or to "correct all irregularities, remove all obstructions, and relieve the distressing symptoms so prevalent with the sex" The names printed after those of newspapers are names of persons with whose trade we have dealt in detail in our previous articles.

At the Hackney Coroner's Court on Monday last Dr. Wynn Westcott held an inquiry respecting the death of an unfortunate woman who died from hæmorrhage consequent on abortion. Evidence was given that the deceased had attempted to obtain medicine for certain purposes from Madame Frain. The jury returned a verdict to the effect that "The deceased's death was due to syncope, the result of hæmorrhage, consequent on abortion, for which no cause has been proved, and the jurors having heard the evidence as to the manner and conduct of the business called that of 'Madame Frain' are of opinion that the business is either fraudulent or felonious." The coroner said that "Madame Frain's" business had at one time a most evil reputation, and THE LANCET had designated the advertisements issued by the firm as "disgusting" No steps had been taken by the proprietors to disprove the insinuation, so he concluded that they did not wish the truth or otherwise of THE LANCET's statement investigated.

[1] Articles I., II., III., IV., V., VI., and VII. were published in THE LANCET of Dec. 10th, 17th, 24th, and 31st, 1898, and Jan. 21st, Feb. 4th, and March 11th, 1899, respectively.

ARMY MEDICAL REPORT FOR 1897.[1]

SECOND NOTICE.

THE Army Medical Report for 1897 with its appendices forms a voluminous publication of some 600 pages altogether. We have already given a first notice of it in THE LANCET of March 11th, 1899, p 718. These reports are valuable in that they contain a mine of information of one kind and another likely to prove of interest to medical officers belonging to the armies of this and other countries. Apart from the health statistics, accompanied by a running commentary for their elucidation and for bringing into prominence the principal features in the medical events which they chronicle, there are numerous articles dealing with the progress of hygiene, especially army hygiene, military medicine and surgery, together with reports on the medical history of any campaigns in which this country has been engaged, papers from the delegates to different congresses, and contributions by individual officers on subjects about which they have either had any exceptional experience or in which they have taken any special interest. We propose, however, to confine our attention in the present article to such points as have occurred to us in turning over the pages of the report. Those who are desirous of going into statistics or of verifying the statements contained in the text can do so by turning to the tabular abstracts, but few people care to encounter a *chevaux de frise* of figures unless compelled to do so or without having some special object in view. We may consequently put these abstracts altogether aside as far as we are concerned and content ourselves with what we find in the remainder of the volume. The report leads off with a copy of the instructions furnished for the guidance of medical officers regarding the revised "Nomenclature of Diseases" (1896 edition) published by the Royal College of Physicians of London and adopted by the Registrar-General. It became necessary, of course, for the Army Medical Service to follow the nomenclature used in civil life in order to ensure for statistical purposes conformity in the classification of diseases and to afford one and the same basis of comparison for both. Alterations of the nomenclature of diseases are obviously necessary from time to time but the result is occasionally somewhat embarrassing to non-medical readers, such as members of the House of Commons who sometimes turn to these reports for evidence for or against the Contagious Diseases Act, for example. *Apropos* of this we may say that in the summary remarks on the health of the troops at home and abroad on page 2 of the report it is stated that the decline in venereal diseases amongst the troops at home which commenced in 1886 and which has practically continued without interruption ever since is again observed in 1897, the greatest decrease being in primary venereal sores. A very marked variation has been noted, however, in the prevalence of these diseases at individual stations. We have always held that one of the principal results of the operation of the Contagious Diseases Acts was the moral and social improvement noticeable in those towns and garrisons where they were in operation. There is no doubt that they exercised a restraining influence on the lax and immodest conduct of many thoughtless girls through fear of their behaviour attracting the notice of the police. It is to be feared that it does not at all follow that the number of cases of this class of disease in any given locality is any reliable measure or indication of its sexual morality. Be this as it may, however, we find that taking all forms of venereal diseases together the admissions in the United Kingdom numbered 13,490 and the constantly sick 1205·31. The total ratio of admissions for these diseases was 139·7 and that of constantly sick 12·48 per 1000; these ratios being lower than those of the preceding year and lower also than the average of the preceding 10 years.

The districts showing the greatest prevalence of venereal diseases were the Dublin, Western, Belfast, and Woolwich. The lowest rates were in the Cork, Scottish, South-Eastern, and North-Western districts. Compared with the distribution of venereal disease in the previous year increase is observed in the admission rates of the Belfast, Channel Islands, and Woolwich districts, but in all the others decrease has occurred, the most marked being in the Western district, in the North-Eastern, in Aldershot, and in the Scottish district. There is no need to advert to the prevalence of diseases of this nature among European troops in India for it is already a matter of common knowledge and serious concern. Turning, however, to the troops serving in China we can form some estimate of the scourge which this class of disease may become. Including all forms, the total admission rate in 1897 amounted to 668·4 per 1000, being a marked increase on that of the previous year and as much as 313·7 higher than the average ratio for the preceding 10 years. The Principal Medical Officer remarks that the statistics of the past two years indicate a persistent and rapid increase both in the number of cases and in the rate of constant inefficiency from these causes, which, if it continues, will probably necessitate a permanent increase in the hospital establishment at Hong-Kong. The contrast between the admission rate for these diseases at Gibraltar and Malta is also noteworthy, 282·7 at the former as against 166·3 per 1000 at the latter station.

As regards the health statistics of the different arms of the service serving in the United Kingdom we find that in 1897 the highest rate of admission was in the Infantry, the next in the Cavalry, and the lowest in the Royal Engineers, the next lowest being in the garrison staff and departments. The highest mortality rate occurred in the Foot Guards, 4·20 per 1000, the next being 4·19 per 1000 in the regimental depôts. In the previous year the highest rate was in the regimental depôts and the next highest in the Royal Artillery. The lowest death-rates in the year under review occurred in the Household Cavalry with 2·54 per 1000, and in the Infantry with 2·78 per 1000. Invaliding was highest in the Infantry, next in the Foot Guards, while the lowest rates occurred in the Royal Engineers. The highest rate of constant inefficiency from sickness was in the Foot Guards with 63·03 per 1000, followed by the Infantry with 44·79 per 1000. The lowest rate, 17·75 per 1000, was in the Royal Engineers, the next lowest being in the garrison staff and departments. The same arms, in similar order, furnished the highest and lowest rates in the preceding year.

The total number of invalids admitted into Netley Hospital from abroad during the year 1897 was 2638, of whom 23 died, 962 were discharged to duty, and 1429 were invalided from the service. It may be here remarked that the Hermite system of sewage disinfection which was installed at this institution some years ago is reported to be working satisfactorily.

A good deal of attention has of late been directed to the provision of accommodation for sick and convalescent soldiers, and we regard this measure as a very important step in the right direction on the part of the present Government. It amounts to a scandal that the nation should not take all reasonable means of aiding soldiers who have been disabled or who have lost their health in its service, and an obvious way of attempting of doing this is by utilising any available accommodation at such stations as afford climatic and other advantages for the establishment of sanatoria or convalescent depôts. A beginning, although on a very small scale, has already been made in this direction. Scarborough and Tynemouth were used for the purpose in 1897. Two classes of convalescents are transferred to these depôts—namely, men who require no hospital treatment but who have not regained strength sufficiently to return to duty and men who require change of air in aid of hospital treatment. For the former barrack-room accommodation is provided. 24 of the latter class were transferred—viz., 22 to Scarborough and 2 to Tynemouth. The Principal Medical Officer remarks that almost all the patients have derived great benefit and the expense has been small.

This system is capable of being largely developed and, we make no doubt, with distinct advantage not only in the way of humanity to the sick and disabled soldier but with benefit to the State in the restoration of many men whose services are now lost to the army by their being permanently invalided—to swell the sick and death-rates as well as to increase the poor-rates of the civil population. At Fleetwood there should be available accommodation. The health of the troops is very good there, and the medical officer in charge regards it as one of the healthiest stations in England and suitable for the transfer of cases from other stations requiring change of air. In the Isle of Wight also—at Golden Hill Fort, for example, when a new hospital is built—there should be excellent positions for accommodating suitable cases requiring change of air and certain climatic conditions for their recovery from attacks of serious or acute diseases and pulmonary complaints. Many other stations will also offer advantages for the establishment of army sanatoria, and some of them should be on inland sites for seaside resorts do not suit all patients returning from foreign service.

---

[1] Army Medical Department Report for the Year 1897, with Appendix. Vol. xxxix. London: Printed for H.M.'s Stationary Office by Harrison and Sons, St. Martin's-lane. 1898. Price 2s. 11d.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE fifty-eighth sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Tuesday, March 7th. The Commissioners *present* were Lord Llandaff, the Right Honourable John Mellor, Sir John Dorington, Mr. de Bock Porter, Mr. Robert Lewis, and Major-General Scott. The witnesses examined were Mr. William Whitaker, F.R.S., formerly senior officer of the English staff in the Geological Survey; Mr. Richard Hack, engineer to the Chelsea Company; Mr. Ernest Collins, one of the engineers to the New River Company; and Mr. George Corble, clerk to the Lee Conservancy Board.

Mr. WHITAKER, in answer to the CHAIRMAN, said that he had given evidence as a witness before Lord Balfour's Commission, partly at the request of the Commissioners and partly on behalf of the London County Council. He had given great attention to the water-bearing strata of Kent and he was of opinion that there was an abundant supply of water there. A great part of the district had a very sparse *population.* With regard to the *amount of rainfall which* percolated the witness said that the calculation showed that the annual percolation was 40,000 gallons of water *daily to the square mile. As a basis of the calculation* of the amount of water which the area produced the witness had taken about half the amount of rainfall as the percolation unit. He had prepared figures in such a way as to show what the available amount of water was supposing that one-third of it percolated, in case half of it percolated, *and in case one-eighth percolated.*

In answer to Mr. MELLOR the witness said that the amount which percolated depended on whether the rainfall were on low or on high ground. On high ground it took longer to percolate than on low ground, and in answer to Major-General SCOTT the witness admitted that it was impossible to say what amount of water did actually percolate.

In answer to the CHAIRMAN the witness said that he *thought that roughly it might be assumed that one-third of the* rainfall percolated. Occasionally a rainfall of three inches might send two inches into the ground and another rainfall of three inches might hardly send any for the water evaporated or got soaked up by the vegetation. The amount which percolated depended greatly on the period of the year at which the rainfall took place; for instance, in the summer the *amount of percolation* was small.

The CHAIRMAN said that Lord Balfour's Commission *assumed that an annual percolation of seven inches was a* proper average to take. The witness said that his impression was that seven inches was an under-estimate. He thought the amount was not less than eight inches. If the amount of percolation was seven inches a year the total annual amount would be 34,500,000 gallons on a daily average, and if the percolation were eight inches it would amount on a daily average to 39,000,000 gallons throughout the year.

Major General SCOTT pointed out that that amount of water *would only* be available if it could be *pumped up from* wells or given off by springs after it had percolated. The witness admitted that a *fair allowance* would have to be made for the water which it was not possible to obtain, but that amount depended very much upon what works were *undertaken to get it.*

Major-General SCOTT suggested that even if a tunnel a mile or two long were made it would not necessarily follow that all the water would be intercepted. The witness thought that very little water would pass over the tunnel.

Major General SCOTT *pointed out that it might* pass under it, and the witness said that that would depend on the depth of the tunnel, and if it were driven parallel with the Thames on the sea level the water on its way to the Thames would be intercepted.

In answer to the CHAIRMAN the witness said that he thought that 9,000,000 gallons of water a day could be obtained from the *greensand in the area of the Kent* Company and that it would be possible to obtain from the chalk from 43,000,000 to 59,000,000 gallons daily.

With regard to the present supply from wells in the Kent Company's district the witness said that he was told that 9,000,000 gallons were obtained daily at Deptford, and that in the *Ravensbourne area 2,000,000* gallons were obtained at Shortlands. With regard to the part of Kent outside the area of the Kent Company the witness thought that *150,000,000 gallons a day could be obtained,* and this amount and the 60,000,000 gallons which could be obtained in the area made a total of 210,000,000 gallons.

In answer to Mr. MELLOR the witness admitted that it would not be possible to get the whole of this water, but he thought that it would be possible to get a good deal of it. He admitted, however, that underground water was such a very doubtful subject that it was impossible to speak with certainty on the matter. At present, however, only half the *60,000,000* gallons which he estimated as a possible amount are obtained in the area of the Kent Company.

Mr. RICHARD HACK, *in answer to Major-General* SCOTT, said that the Chelsea Company were increasing the capacity of their reservoirs at Molesey. The work now being carried on is that the banks of the existing reservoirs are being raised so that their capacity will be increased to 50,000,000 gallons. This will be sufficient for a 14 days' supply. The depth of the reservoirs will be 23 ft. One of the reservoirs was cleaned three years ago. It was the custom of the company to clean each reservoir periodically once every eight years. The amount of deposit which was found was one inch of dry sediment. The lowest four feet of the reservoir contained water which would quickly block a filter bed if it were put on it. The bottom water contained a large amount of solid matter in suspension and if this were used the filters would have to be cleaned much more often than they are at present. The solid matter would be deposited on the surface of the filters and it would not be economical to use such water. The Chelsea Company were in the habit of closing their intake from the Thames in time of flood. They *did this because flood water contained a large amount of* matter in suspension and this had to be deposited. Moreover, flood water was discoloured, so that it was impossible to get rid of all the colour by filtration. The witness said that for these reasons it was better to avoid taking flood water altogether. *He did not think that the inferiority of flood* water was entirely overcome *by means of filtration.* If it were used it would be necessary to have larger reservoirs or a larger filtration area.

In answer to Mr. DE BOCK PORTER the witness said that he did not think it was necessary that reservoirs should be cleaned once in eight years. It was the practice of the Chelsea Company to clean them so frequently because they had to deal with a large quantity of deposit. They obtained something like 1000 cubic yards of deposit from an area of eight acres.

In answer to Mr. MELLOR the witness *explained* that the bottoms of the reservoirs were not paved but consisted of ballast gravel and that the reservoirs were made watertight *by puddle* walls which *passed* down to the London clay.

In answer to the CHAIRMAN *the witness said that it was not necessary* that the bottom of the reservoirs should be puddled because the water could not pass through the layer *of clay* and the bottom of the reservoir was 12 ft. above it, *so that there were 12 ft. of gravel into* which the water in the reservoir could sink.

In answer to Mr. MELLOR the witness said that it was not *necessary* that this gravel should be washed.

The CHAIRMAN pointed out that the allowance of four feet for bottom water was *nearly one-fifth and it did not agree* with the figures which had been given by Mr. Middleton.

In answer to Major-General SCOTT the witness said that they occasionally took water which was turbid into their reservoirs, but they never did so when they could avoid it. They preferred when possible not to take flood water for nine days after a flood, sometimes they were obliged to take it more quickly, but the shortest period at which he remembered having taken water was four or five days after flood.

In answer to Major-General SCOTT the witness gave a description of the construction of the filter-beds used by the company (this information has already been given in THE LANCET of March 6th, 1897).

In answer to Mr. DE BOCK PORTER the witness said that the usual duration of the life of a filter until it was cleaned was nine weeks; at the end of that time the sand had to be washed.[1] The longest time which the witness had known a filter to last without clogging was 16 weeks and the shortest period was five or six weeks. He had never found it necessary to clean one more frequently than once in five weeks.

In answer to Major-General SCOTT the witness said that the maximum amount of water which they could pass through their filters collectively was about 14,000,000 gallons; if more water were wanted they would equalise the work by drawing from the Putney reservoirs. (The reservoirs at Putney are capable of storing 11,000,000 gallons.) The slowest rate of filtration which they allowed to occur before disusing a filter was about one a half gallons per square foot per hour. He did not know of a case in which they had been obliged to exceed the rate of two and a half gallons per square foot per hour. He did not think that regulations with regard to filtration which had been recommended by Lord Balfour's Commission were necessary in the case of the Chelsea Company. At the present time each filter-bed was not supplied with a separate well but one was to be provided as soon as it could be made. The witness did not think that there would be any advantage in having an automatic arrangement to record the rate of filtration but would rather depend on the method which he adopted of using standard gauges on the sand; he had less confidence in an apparatus but he had never seen one at work. He thought that an automatic record would be a good thing if it were reliable but for his own part he preferred the method which was at present in use, that of personal supervision.

In answer to Major-General SCOTT the witness said that they were placing sea sand on their filters at the present time and that this change had probably been adopted on the recommendation of Sir Edward Frankland.

Mr. ERNEST COLLINS, in answer to the CHAIRMAN, said that he had prepared some tables showing the saving which had taken place in the amount of water distributed by the New River Company since they had used Deacon's waste meter system and had visited the houses of their customers to see in which the loss of water was taking place. The public had very generally accepted and adopted the use of the fittings which the company had previously examined at their testing office[2] and which they stamped. In the case of new houses stamped fittings were used in 95 per cent. of the cases and in most of the other cases the apparatus used was now good. The fittings which they examined were tested and the witness attributed most of the success which they had had in suppressing waste to the use of properly tested fittings of good manufacture and in his opinion water consumers should be compelled to use such fittings.

The tables which the witness put in showed the rate of supply per head in the district of Shoreditch, comparing the consumption in 1882 previously to the introduction of the waste meter system with the consumption after its introduction in 1893-4 and up to the year 1898. The amount supplied daily per head had been reduced from 35·8 gallons to 15 gallons.

The CHAIRMAN asked the witness how he separated consumption of water from waste of water, and the witness explained that as a rule water was not used between the hours of 12 midnight and five in the morning, and that water which passed through their mains at that time was, as a rule, wasted by the customer through defects in the fittings.

The CHAIRMAN remarked that it seemed from the evidence of the witness that there must be an enormous amount of water wasted in the districts of some of the metropolitan water companies.

Major-General SCOTT pointed out that the average daily consumption per head in the district of the Grand Junction Company is 48 gallons and the chairman remarked that it was 42 gallons in the case of the Southwark and Vauxhall Company.

An interesting table was put in showing the supply per head per day in the Tudor-street district of the city where the supply was for printers and for other traders and utilised by day and by night by a shifting population. In this district the population is 1082, the average daily consumption per head is 59·4 gallons, of this consumption 32·8 gallons are used during the day and 26·6 are "wasted" (used) during the night.

In answer to the CHAIRMAN the witness pointed out that in parts of their district an enormous quantity of water was "wasted" by watering gardens. Some customers allowed their hoses to run in the gardens all night. The company suffered most terribly in the summer time from those sprinklers which are put out in gardens to water lawns.

Major-General SCOTT said these were easily visible objects and suggested that their inspectors might object to their use.

The CHAIRMAN thought that if the customers paid for their water they might think they were entitled to use as much as they liked. The witness said that he was afraid that that was the case. The company endeavoured to check the "waste" (use) of water as much as possible and they remonstrated with the people.

Mr. GEORGE CORBLE, on behalf of the Lee Conservancy Board, gave evidence as to the pecuniary resources of, and the methods adopted by, the Board of which he is clerk.

The fifty-ninth sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Monday, March 13th. The Commissioners present were Lord Llandaff (the Chairman), Sir John Dorington, Sir George Bruce, Mr. de Bock Porter, Mr. Cripps, Mr. Robert Lewis, and Major-General Scott. The witnesses examined were Mr. John Hollams, Mr. Urban Armstrong Smith (surveyor and engineering adviser of the Hertfordshire County Council), and Mr. Baldwin Latham, civil engineer, who gave evidence on behalf of the Hertfordshire County Council.

At the commencement of the sitting Mr. BALFOUR BROWNE, Q.C., on behalf of the London County Council, made a statement as to the policy which that body proposed to adopt. This statement was made in answer to a request from the CHAIRMAN who said at one of the earlier sittings that the Commissioners wished to know whether the London County Council desired that the Commissioners should advise that purchase of the water companies' undertakings was expedient on any terms of arbitration, or whether they wished them to find that purchase would be expedient only upon special terms of arbitration. Mr. Balfour Browne explained that his clients had reduced to writing the answer which they desired to make and he read a written statement in order that he should not himself put in a word that he was not authorised to state. The statement is as follows:—

We would point out that the doubt which still seems to be entertained by some members of the Commission is no doubt due to the fact that throughout the present inquiry the object of the committee has been, not so much to make one particular case which they ask the Commission to accept as to lay before the Commission all the information relating to the water-supply of the metropolis which several years of experience have enabled them to collect and upon which the Council's policy has been based. In order to enable *the Commission to* appreciate this policy the committee have laid before them the decisions arrived at by the *Council and the specific schemes* for the solution of the water question which the Council has presented to Parliament. The Council's Bill for the purchase of the eight companies is now before Parliament, and it contains a special arbitration clause which is the clause which was discussed before Mr. *Plunket's Com*mittee in 1895, and this clause affords in itself the answer to the Chairman's question—namely, that in the opinion of the *Council it* is expedient to purchase the companies upon special terms of arbitration. With regard to the question whether the *Council thinks* that purchase is expedient upon any terms of arbitration we would point out with the greatest respect that as the Council's definite proposal is now before Parliament and the Council's witnesses may at *some* time be called upon to substantiate it before a *Committee* of the House of Commons it is impossible for the committee to say anything that might be construed so as to commit the Council to accept any terms of arbitration that might be imposed *upon it.* At the same time the committee wish it to be *stated that* in their opinion it does not necessarily follow that the precise clause contained in the present Bill affords the only means of obtaining fair terms of arbitration. The Council's view has been that the *position of* the metropolitan water companies differs in many respects from that of similar undertakings with which Parliament has hitherto dealt, and its contention is that the fair value of the companies' undertakings should be ascertained by a court of arbitration of the highest *standing* with the fullest powers to inquire into all the circumstances of each individual case.

Mr. CRIPPS remarked that there was a reference to a Bill which had been brought in by the London County Council and of course the terms of this Bill were known to the metropolitan water companies. A question which seemed important was whether it was usual in private Bills to introduce a long preamble reciting the whole case as to the charges which the promoters made against other parties. He noticed that the preamble of the Bill extended to three or four pages and that it recited charges that were made against the metropolitan water companies in former times and he asked whether this was a usual course to adopt.

---

[1] In the case of some of the other companies the filter beds are cleaned as a rule about once in five or six weeks. These companies take in flood water from the Thames.

[2] See the account of the workshop of the New River Company as given in THE LANCET of Dec. 4th, 1897.

Mr. BALFOUR BROWNE replied that they would of course have to prove the preamble of their Bill and that the practice with regard to the introduction of a long preamble differed very much in different cases but that as late as last year there was a long preamble in the case of the Tilbury Bill, for which Mr. Littler, Q.C., appeared as counsel.

Mr. JOHN HOLLAMS, on behalf of some of the metropolitan water companies, gave evidence with regard to a report on the London Water-supply of the Parliamentary Committee appointed in the year 1821, and with regard to a Government Bill which was introduced into Parliament in the year 1851. By this Bill it was proposed to amalgamate the companies, to constitute a board of directors consisting of 12 persons who were to be remunerated, and the compensation was to be settled by arbitration under the Lands Clauses Act The witness said that he gathered also from the proceedings that the companies were then paying about 6 per cent. on their capital. The arrangements proposed by the Bill were that a new water stock should be created to bear interest at 5 per cent., and that the existing rates were to be continued until there was a surplus and then the rates were to be equalised in the respective districts, then if there was again a surplus the stock was to bear interest at 6 per cent. and after paying 6 per cent. all the profits were to go to the consumers. The Bill contained a schedule to specify the rents which were to be charged, but this schedule was never filled up. The Bill was brought in under Lord John Russell's administration and a committee was appointed to make a report upon it After a great deal of evidence had been taken by the Parliamentary Committee on August 5th, 1851, Sir James Graham, chairman of the Committee, made in Parliament an explanation of his position and moved that the evidence which had been taken before the Committee on the Metropolitan Water Bill should be printed. He said that after an inquiry which had lasted between 30 and 40 days the House would probably expect that he should state how matters stood. The Committee had investigated the case on the part of the promoters of the Bill. That part of the evidence was complete. They had proceeded to take the evidence of those who contended for the advantages of establishing a control of the undertakings by some municipal body elected by the people. That part of the evidence was also complete. The evidence of the existing water companies had been given at considerable length but it was not finished. The Committee advised that the evidence should be printed with a view of affording information to the public. The Committee did not feel that they were in a position to give any opinion upon the evidence, and he therefore moved that it should simply be printed as it stood. In the following February Lord Seymour introduced a Bill into Parliament and this Bill was based on entirely different lines from those of the preceding one. In introducing the Bill Lord Seymour said that it would be best for the companies to act either separately or in conjunction as they might choose If municipal bodies, inexperienced as they were, were to be suddenly called together (divided, as doubtless would be the case, by party feeling) to supply water for the necessities of the town great delay would unquestionably arise. Lord John Russell's Government went out of office in 1852 and Lord Derby's first administration was formed Lord John Manners (who succeeded Lord Seymour in office) on March 25th, 1852, moved that it should be an instruction to the committee of selection that they have power to fix the committee on the Metropolitan Water Bill for April 1st. He said that he did not pledge himself to support the measure introduced by his predecessor in office because in one important item, that relating to the scale of charges, the Government of which he was a member dissented altogether from the previous one. In the meantime the companies had introduced Bills which resulted in their Acts of 1852 and the Government Bill went before a Special Committee. The Committee decided not to hear evidence on the preamble and Mr. Mellor, the counsel for the Government, proceeded to deal with the clauses Amongst other things Mr. Mellor contended that if a house were within the area of more than one water company he apprehended that the householder had a right to be supplied from which source he pleased. Ultimately a Bill was promoted which became the Metropolis Water Act of 1852.

Mr. URBAN ARMSTRONG SMITH, in answer to the Chairman, said that he had investigated on behalf of the Hertfordshire County Council the water levels in the chalk of that county and the factors which govern the rise and fall of the springs and streams. The CHAIRMAN at once informed the witness that the Commissioners had decided that they would not reopen those questions which were decided by the Balfour Commission, but they would hear the witness on any new fact which had occurred since the sitting of the Balfour Commission which would throw new light upon the subjects into which they had to inquire. The witness said that he considered it a matter of importance that the New River Company had shown consciousness that their supplies from the Lee were deficient because they had joined in the Staines Reservoirs Scheme. The drought in the year 1898 had thrown light on the subject of the diminution of the supply of water in Hertfordshire in a number of ways: the rivers have been lower than at any previous period, the wells had been very much lowered, and they had the great fact before them that Chadwell Spring which had never been known to be dry before had failed last autumn. In addition to these facts the rise in the River Lee was less than it had ever been before and the wells in the Lee valley were lower.

The CHAIRMAN remarked that the witness had prepared a large number of tables relating to the Chadwell Spring and asked from what source the figures were obtained. The witness replied that some of them had been given by Mr. Francis, the engineer of the New River Company through their representative, Mr. Hollams. One of the tables which was put in showed the average daily flow of Chadwell Spring in three-year periods from 1875 to 1898; another table showed the average daily flow in four-year periods; a third table showed the average daily flow in five-year periods; a fourth table showed the average daily flow in six-year periods; a fifth showed the average daily flow in seven-year periods, and a sixth table showed the average daily flow in eight-year periods. The table showing the flow of Chadwell Spring in three-year periods showed a decline of 43 per cent. between the averages of the three years 1875-77 and the three years 1896-98. During the second of those two periods the reduction in the rainfall was less than 16 per cent.

Mr. POPE, Q.C., said that some of the figures had previously been given to Lord Balfour's Commission and suggested that the witness "had manipulated the tables afresh."

Lord ROBERT CECIL replied that they had expressly avoided manipulating the figures: they restated the figures in another form in order to avoid the charge that they had manipulated them in any way and the tables showed that whatever way the thing was taken the result was the same—that is to say that there had been a steady decrease in the flow from Chadwell spring. (The figures were of very great interest but as they occupy many pages it is impossible that they can be reproduced in THE LANCET and it must suffice to state that they can by no ingenuity be made to bear any other interpretation than that given to them by Lord Robert Cecil.)

With regard to the entire failure of the spring in the autumn of 1898 Mr PEMBER, Q.C., pointed out that Mr. Francis had already explained that it was due to a "crack in the basin" and it was suggested that the company had pumped out the water in order to mend the crack. Major-General SCOTT, however, pointed out that if the basin had no aperture it would be impossible for any water to get into it.

The witness said that the well at Haileybury College had been greatly affected by the pumping at the station at Rye Common. According to the evidence of the bursar of the college the pump at Rye Common was not worked on Sundays and on that day there was a rise of water in the well of the college. During the autumn of 1898 the New River Company pumped water from the site of the Chadwell Spring and this pumping lowered the water in the wells in the neighbourhood. On this matter many details were given and plans were shown giving the level of the water in the wells at different dates. The witness said that Hertford is supplied by a well which is from 70 feet to 100 feet in depth, but the amount pumped from it was only 200,000 or 300,000 gallons daily and this direction of the Lord President of the Privy Council, a circular relating to an international conference respecting the adoption of precautionary measures against syphilis and venereal diseases to be held at Brussels from Sept. 4th to 8th, 1899, and stating that Her Majesty's Government, while not proposing to be directly represented at that conference, are of opinion that it might be desirable that the various medical corporations of the United Kingdom should, if they think proper, take steps with a view to representation thereat. Mr. Alfred Cooper was appointed a representative of the College and Mr. Hutchinson was requested to act also as a representative of the College.

A letter was read from Mr. E. White Wallis, secretary of the Sanitary Institute, stating that the Autumn Congress and Exhibition of the Institute will be held at Southampton on August 29th and following days and inviting the College to appoint two delegates to attend the Congress. Mr. Howard Marsh and Dr. Ward Cousins were appointed delegates.

Mr. BRYANT moved :

> That in view of the centenary in 1900 of the foundation of the College by Royal Charter a committee be appointed to consider and report to the Council whether any, and if so what, steps should be taken to celebrate the event.

The resolution was carried and a committee was appointed.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Upon Measles in the Borough of Burton-on-Trent, by Dr. THEODORE THOMSON.[1]—Since his report upon measles in England and Wales, which appeared in the annual volume of the Medical Department of the Local Government Board for 1894-95, Dr. Thomson has continued his investigations in localities where, owing to the disease being compulsorily notifiable or to other circumstances, the etiology of measles and the application to measles of preventive measures can be advantageously studied. The last of Dr. Thomson's reports on the subject was upon a severe outbreak of measles in Lancaster in 1897. The present report deals with similar prevalence of the disease in Burton-on-Trent last year. In all 1015 cases of measles came to the knowledge of the local authority between Jan. 2nd and August 13th. The estimated population of Burton being 51,664, the attack rate per 1000 persons living was thus 39. Only 29 persons died, giving during these seven and a half months the low fatality rate of 14 per 1000 and a death-rate per 1000 of 0·56. The age distribution of the cases in respect of attack and death is given by Dr. Thomson in the following table :—

Age groups.	Estimated population.	Attacked by measles.	Deaths from measles.	Measles attack-rate per 1000 living.	Measles death-rate per 1000 living.	Measles fatality rate per 1000 attacked.
At all ages	51,664	2,015	29	39	0·56	14
0—1...	1,430	148	6	103	4·2	40
1—2...	1,425	217	11	152	7·7	50
2—3...	1,495	235	9	157	6·0	58
3—4...	1,356	309	1	228	0·7	3
4—5...	1,445	315	1	218	0·7	3
Under 5...	7,151	1,224	28	171	3·9	23
5—10	7,150	680	1	95	0·1	1
10 and upwards ...	37,363	111	—	3	—	—

It will be seen that, on the whole, the Burton experience accords with corresponding data which have been obtained in previous epidemics of measles. The chief incidence of *attacks* was in children in the second, third, fourth, and fifth years of life, and more especially in children in the fourth and fifth years, while the chief incidence of *deaths* was in children in the first, second, and third years, and more especially in those in their second year.

That the death-rate from measles in children under one year is commonly considerably less than the rate in children between one and two years has often been apparent from mortality returns. Until lately it has not been possible to do more than surmise whether this difference is due solely to a smaller frequency of exposure to infection which may be assumed in the case of quite young infants. Dr. Thomson's table shows that for Burton in 1898 this was not a complete explanation. The attack-rate for infants under one year was, it is true, less in the proportion of from two to three than the corresponding rate for children between one and two years. But the fatality rate in the first class of cases was also less, the ratio being from four to five. It must, however, be borne in mind that a good many inaccuracies almost inevitably arise in statements of the ages of infants and that the extent of this error is likely enough to be greater in notification of infectious disease than in certification of death. Before definite conclusions can be come to as to the meaning of the differing rates of mortality from measles at the several age-periods, statistics in such form as Dr. Thomson's tables are needed from a large number of different localities and for a series of years. Health officers of districts in which measles is compulsorily notified could in many cases furnish valuable information on this subject.

The relation of school attendance to the maintenance of the epidemic, and particularly to the excessive incidence of the disease upon children between three and five years of age, is discussed in detail in an appendix to the report. "There was no great extension of the disease," observes Dr. Thomson, "until it had gained a foothold among children attending school. This suggests that schools had a large share in the dissemination of measles." Closure of certain schools of the town was resorted to, but the benefit derived from school closure was not very pronounced, probably in large measure because there was too much delay in closing schools and because in invaded areas of the town certain schools were allowed to continue open when their neighbours had been closed on account of measles. The sundry precautions adopted by the Burton Town Council on the advice of Mr. T. Robinson, the medical officer of health, are set out at length and they contain much which calls for commendation and which might be applied elsewhere with prospect of advantage. And so far as the results of precautionary measures were found disappointing, they were chiefly to be attributed to the lack of thoroughness with which these measures were put into practice. "It is doubtful whether the sanitary staff suffices to cope with the ordinary work falling on the health department of a town the size of Burton; it is quite insufficient for the added labour of measures undertaken with a view to control an epidemic of measles." Dr. Thomson lays stress upon the great use of isolation in hospital of cases of measles if employed in inter-epidemic periods, when the isolation accommodation needed is relatively small and when the value to be obtained from isolation is at its greatest.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6694 births and 5099 deaths were registered during the week ending March 18th. The annual rate of mortality in these towns which had increased in the four preceding weeks from 19·5 to 22·2 per 1000 further rose last week to 23·3. In London the rate was 24·1 per 1000, while it averaged 22·8 in the 32 provincial towns. The lowest death-rates in these towns were 12·7 in Derby, 16·4 in Portsmouth, 16·5 in Hull, and 16·6 in Leicester; the highest rates were 28·0 in Oldham, 28·8 in Liverpool, 31·5 in Salford, and 31·9 in Manchester. The 5099 deaths in these towns included 417 which were referred to the principal zymotic diseases, against 437 and 409 in the two preceding weeks; of these 136 resulted from whooping-cough, 103 from measles, 88 from diphtheria, 37 from "fever" (principally enteric), 32 from diarrhœa, and 21 from scarlet fever. The lowest death-rates from these diseases were recorded in Croydon, Brighton, Cardiff, and Newcastle-upon-Tyne; and the highest rates in Wolverhampton, Salford, Blackburn, and Preston. The greatest mortality from measles occurred in West Ham, Manchester, Salford, and Leeds, from scarlet fever in Oldham, from whooping cough in Plymouth, Swansea, Birkenhead Preston, Bradford, and Hull, and from "fever" in Wolverhampton The 68 deaths from diphtheria included 45 in London, seven in Sheffield, five in Liverpool, four in Leicester, and three in Swansea. No fatal case of small pox was registered during the week under notice either in London or in any other of the 33 large towns, and only one small pox patient was under treatment in the Metropolitan Asylums Hospitals on Saturday last, March 18th The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 2437 against 2584 and 2540 on the two preceding Saturdays, 224 new cases were admitted during the week, against 241, 236 and 217 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London which had been 470 and 529 in the two preceding weeks, further rose last week to 565 and were 61 above the corrected average The causes of 71, or 1 5 per cent, of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in Bristol, Cardiff, Nottingham, Salford, and in nine other smaller towns, the largest proportions of uncertified deaths were registered in Liverpool, Blackburn, Preston, and Sheffield

---

[1] London, Eyre and Spottiswoode, East Harding-street; Edinburgh, John Menzies and Co.; Dublin, Hodges, Figgis, and Co. 3d.

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in the eight Scotch towns which had been 25 1 and 22 8 per 1000 in the two preceding weeks further declined to 21 0 during the week ending March 18th, and was 2 3 per 1000 below the mean rate during the same period in the 33 large English towns The rates in the eight Scotch towns ranged from 17 5 in Leith and 18 4 in Edinburgh to 21 9 in Glasgow and 27 3 in Aberdeen The 640 deaths in these towns included 34 which were referred to measles, 27 to whooping cough, 13 to diarrhœa, six to "fever," five to scarlet fever, and five to diphtheria In all, 90 deaths resulted from these principal zymotic diseases, against 99 and 67 in the two preceding weeks These 640 deaths were equal to an annual rate of 2 9 per 1000, which was 1 0 above the mean rate last week from the same diseases in the 33 large English towns The fatal cases of measles, which had been 33 and 13 in the two preceding weeks rose again to 34 last week of which 18 occurred in Glasgow and 12 in Aberdeen The 27 deaths from whooping cough showed a slight further decline from the numbers recorded in recent weeks and included 10 in Glasgow, nine in Edinburgh, and four in Dundee The deaths referred to different forms of "fever which had been six and four in the two preceding weeks, rose again to six last week, of which four occurred in Glasgow and two in Edinburgh The five fatal cases of scarlet fever corresponded with the number in the preceding week and included three in Glasgow where four of the five deaths from diphtheria were also recorded The deaths referred to diseases of the respiratory organs in these towns, which had been 213 and 172 in the two preceding weeks, further declined to 138 last week, and were 23 below the number in the corresponding period of last year The causes of 33, or more than 5 per cent, of the deaths in these eight towns last week were not certified

HEALTH OF DUBLIN

The death rate in Dublin which had been 31 9 and 28 5 per 1000 in the two preceding weeks rose again to 32 4 during the week ending March 18th During the past four weeks the death rate in the city has averaged 30 8 per 1000, the rate during the same period being 22 5 in London and 23 0 in Edinburgh The 217 deaths registered in Dublin during the week under notice showed an increase of 26 upon the number in the preceding week, and included 12 which were referred to the principal zymotic diseases, against 17 and 14 in the two preceding weeks, of these, 10 resulted from whooping cough and two from diphtheria, but not one either from small pox, measles scarlet fever, "fever," or diarrhœa These 12 deaths were equal to an annual rate of 1 8 per 1000 the zymotic death rate during the same period being 2 0 in London and 2 6 in Edinburgh, The fatal cases of whooping cough which had been five in each of the two preceding weeks rose to 10 last week, and exceeded the number recorded in any week since May, 1897. The two deaths referred to diphtheria also exceeded the number returned in any recent week The 217 deaths in Dublin last week included 35 of infants under one year of age and 58 of persons aged upwards of 60 years, the deaths both of infants and of elderly persons showed a slight further increase upon the numbers recorded in recent weeks Six inquest cases and three deaths from violence were registered, and 87, or more than a third, of the deaths occurred in public institutions The causes of 15, or nearly 7 per cent, of the deaths in the city last week were not certified

THE SERVICES.

Royal Navy Medical Service

Staff Surgeon Herbert Elliott Marsh has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet

Inspector General T H Knott will succeed Inspector-General H Macdonnell, C B, at the Royal Naval Hospital, Haslar, on the retirement of the latter officer in June next

The following appointments are announced —Staff Surgeon C Bradley to the *Colossus*, temporary Surgeon J C Fergusson to the *Victory*, for disposal

Royal Army Medical Corps

Lieutenant J S Gallie holds himself in readiness to embark for Mauritius Major A S Rose is ordered to St Helena and Lieutenant A E Weld to South Africa, for service Major C H Burtchaell has joined at Woolwich Major A Stables, on arrival in India, is attached to the Poona Station Hospital Captain Henry A Berryman is placed on temporary half pay on account of ill health

Army Medical Reserve of Officers

Surgeon Lieutenant Charles Edward Reading Bucknill, 2nd Volunteer Battalion the East Lancashire Regiment, to be Surgeon Lieutenant

Volunteer Corps

Artillery 1st Edinburgh (City) Robert Black Purves to be Surgeon Lieutenant 1st Forfarshire Surgeon Lieutenant J I Sturrock resigns his commission *Rifle* 2nd (the Weald of Kent) Volunteer Battalion the Buffs (East Kent) Regiment Joshua Law Kerr to be Surgeon Lieutenant 5th (the Hay Tor) Volunteer Battalion the Devonshire Regiment William John Stephens to be Surgeon Lieutenant 1st Nottinghamshire (Robin Hood) Surgeon Captain W J Sprott resigns his commission 1st London Surgeon Captain E A Hughes resigns his commission 1st Volunteer Battalion the Manchester Regiment John Orr to be Surgeon Lieutenant

Volunteer Medical Staff Corps

The Manchester Companies Surgeon Lieutenant W Gill resigns his commission, Surgeon Lieutenant A Phillips to be Surgeon Captain

The Late Outbreak of Fever at Quetta

The new Army Medical Blue Book for 1897 contains a long and exhaustive report on a severe outbreak of enteric fever among the British troops serving at Quetta during 1896 The report is by Major F R Newland, M B Dub R A M C The strength of the European garrison was 2 300, and between April 3rd and Dec 1st there were 141 cases admitted to the station hospital There has likewise been an outbreak of the same fever during the past year The *Army and Navy Gazette* states that a large number of soldiers belonging to that garrison died from the disease during the six months which ended on Dec 31st last Quetta has proved an exceptionally unhealthy station for some years past It was announced more than a year ago that in consequence of the heavy mortality from enteric fever among British soldiers the Government in India had under consideration a proposal to apply for the services of Dr Wright, Professor of Pathology at Netley

Deaths in the Services

Deputy Inspector General Joseph Jee, V C, C B (retired), Honorary Surgeon to the Queen, on March 17th, at his residence Queniborough Hall, near Leicester

Staff Surgeon J Rose (retired) at Chesterfield on March 7th aged 76 years He entered the Royal Navy as Assistant Surgeon in 1847 and served in the *Frolic* during 1848-52 He was at the insurrection of Cephalonia, 1849, and in the following year attended a cholera epidemic in his own vessel as well as on board the [illegible] On [illegible] to England he was appointed [illegible] Haslar Hospital

Correspondence.

"Audi alteram partem."

"DIFFICULTIES UNDER THE NEW VACCINATION ACT."

To the Editors of THE LANCET.

SIRS,—With your permission I should like to reply to the letters of "P. P." and "General Practitioner" in your issue of March 11th, and then I have done with the matter. Both these gentlemen seem to consider it "offensive," "undignified and unprofessional," and "irksome" to arrange *with their own patients* a suitable time for "vaccinating those babies they have brought into the world." Surely the family practitioner can settle so small a matter soon after the mother's confinement without loss of dignity, be he never so self-important. To say that such arranging for the child's vaccination at a later stage is either "unprofessional" or "offensive" is simply an abuse of language.

I am, Sirs, yours faithfully,
THOS. FREDK. I. BLAKER,
Preston Park, Sussex, March 20th, 1899. Public Vaccinator.

To the Editors of THE LANCET.

SIRS,—Your correspondent "Fairplay" now attempts to justify the new "duties" of the public vaccinator by declaring that it is also the duty of the private practitioner to visit and offer to vaccinate. I am certain that it is not his duty, and that such offers of professional services are most objectionable. The space for vaccinations in the ordinary visiting lists is for the names of those whom the practitioner has been asked to vaccinate, and for no others. "Fairplay" might just as well suggest that the space for obstetric engagements is for the names of those whom the practitioner has heard are *enceinte* and are to be called on with offers of professional services. Such visits are most offensive to many people who look upon them as an attempt to establish a medical tyranny; they are contrary to the ethical laws that govern our profession and must be irksome to most medical men. I hope, Sirs, when you give your ruling in this matter, you will not lend your countenance to this system of "calling for orders" which has been advocated by more than one of your correspondents.

I am, Sirs, your faithfully,
March 20th, 1899. P. P.

To the Editors of THE LANCET.

SIRS,—The list supplied to me this month by the vaccination officer contains the names of many children who were over four months old prior to August 31st, 1898, for me to notify and visit according to the new Vaccination Act.

The clerk to the board of guardians for this district has since informed me that the vaccination officer had no right to have given the names "of what I call defaulters and wholesale law breakers of the Vaccination Act" to me; he also told the vaccination officer that he should refuse to pay the account when sent in by me. By this I suppose he means the minimum fee of 1*s*. and the vaccination fee for these older children. As this may happen to other public vaccinators, may I ask you through the columns of THE LANCET if I cannot recover both minimum and vaccination fees in all cases of older children that I have notified, visited, and successfully vaccinated, also if I can claim the minimum fee for these older cases I have notified and visited but have not vaccinated? Will you also inform me how, when, and by whom the new Act provides for dealing with these older cases, as I have been asked time after time the following question: "Why are So-and-so and So-and-so who have children much older than mine allowed to escape and nothing done to compel them, whilst I am pounced upon, which is most unfair?" I think you will agree with me that these women made a very just complaint, and to my thinking the sooner these wholesale law-defiers are dealt with, the more general will vaccination become than it is at the present time.—I am, Sirs, yours faithfully,

March 20th, 1899. ANOTHER PUBLIC VACCINATOR.

"THE REMOVAL OF ADENOIDS IN INFANCY."

To the Editors of THE LANCET.

SIRS,—With reference to an annotation in THE LANCET of March 11th under the above heading an account of the following case may interest you. A female child, aged 14 weeks, was lately brought to the Birmingham and Midland Ear and Throat Hospital suffering from very marked obstruction to respiration and a diagnosis of post-nasal growths was made. Mr. F. Marsh, honorary surgeon to the hospital, decided to remove them at once. The child was placed under chloroform and the growths were removed with the aid of a small StClair Thomson forceps, after an attempt to use the finger had shown that thereby injury to the velum would ensue. The operation was entirely successful and in three days the patient left the hospital completely relieved. The child had been largely reared on starchy food.

I am, Sirs, yours faithfully,
R. FELIX RYLAND, M.R.C.S. Eng., L.R.C.P. Lond.,
House Surgeon to the Birmingham and Midland Ear and Throat Hospital.
March 14th, 1899.

UNRESTRAINED LUNATICS.

To the Editors of THE LANCET.

SIRS,—The difficulty in certifying mentioned in a leading article in THE LANCET of March 11th is met by medical men joining the Medical Defence Union which supplies a form of indemnity against actions to its members. During recent years I have declined to certify in cases of insanity unless such a form is signed by the petitioner; in no case in my experience has that indemnity been refused, although it has sometimes been signed reluctantly. The production of that document to a lawyer or a court would be proof that "reasonable care" had been taken. None conversant with this subject can dispute your observation that the state of the law concerning it is unsatisfactory; but when we obtain the indemnity we are no longer liable to "vexatious, harassing, and costly litigation."

I am, Sirs, yours faithfully,
March 20th, 1899. STANLEY HAYNES, M.D. Edin.

HUNTER *v.* CLARE: AN APPEAL.

To the Editors of THE LANCET.

SIRS,—Permit me through your columns to appeal to the profession for subscriptions to a fund for the assistance of the widow of the late Mr. Kingsley Hunter, L.S.A., of Gamlingay. Her pathetic letter published in your issue of March 11th caused me to enter into communication with her in order to get her sanction for this letter. She informs me that the whole of their capital was expended in the purchase of the practice at Gamlingay, which was utterly ruined by the prosecution of her husband, and she is left penniless and will soon be homeless. I sincerely hope that a practical expression of the sympathy which I am sure most of my professional brethren must have for her will be the outcome of this appeal.

Cheques should be made payable to "The Hunter Fund" and may be sent to Gillett's Bank, Oxford, or to

Yours truly,
RIVERS WILLSON.
42, Wellington-square, Oxford, March 20th, 1899.

To the Editors of THE LANCET.

SIRS,—Referring to Dr. Major Greenwood's letter in your last issue I earnestly hope that some effort will be made to assist the unfortunate Mrs. Hunter. I should be quite willing to give a small subscription and I think there must be many others throughout the country who would be glad to contribute their "mite" if only to show their disapprobation of the prosecution of the late Mr. Hunter.

I am, Sirs, yours faithfully,
M. L. DHINGRA, M.D. Edin., D.P.H. Camb.
Finsbury-park-road, N., March 20th, 1899.

To the Editors of THE LANCET.

SIRS,—I shall be happy to give a small contribution towards any fund that may be raised for Mrs. Hunter.

Personally, I strongly disapprove of the action of the General Medical Council in instituting this prosecution and I think Mrs. Hunter is deserving of much sympathy.

I am, Sirs, yours faithfully,
ROBERT A. FRYER, M.B. Edin.
New North road, N., March 22nd, 1899.

"SALIPYRIN IN INFLUENZA."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 18th appears a letter from Dr. Butler Harris drawing attention to the excellent results obtained by the use of salipyrin in influenza. As I have been using a similar compound for two or three years with most rapid relief of the headache, backache, fever, and malaise of influenza, and without any untoward symptoms following its use, I beg to submit it to the readers of THE LANCET. The formula I generally use is as follows: acetanilide, 30 grains; spirit of chloroform, two drachms; spirit of camphor, one drachm; salicylate of soda, one and a half drachms; water to six ounces; one ounce to be taken every four hours until relieved. In dispensing this, owing to the slight solubility of acetanilide, the spirit should be added first and the water added by degrees. The mixture contains always light flocculent crystalline masses floating near the surface and directions have to be given that the mixture must be well shaken each time of taking. Even in cases where the pulse is most feeble I have seen rapid improvement without the slightest bad symptom, evidently owing in some measure to the stimulating effect of the camphor and alcohol. In most cases the sense of relief is attended by copious perspiration. The cost of the above combination is so much less than salipyrin that I recommend it especially to those practitioners who like myself have a great number of poorer-class patients who cannot afford to pay for very expensive prescriptions. I have three times had occasion to use it myself when attacked by influenza and each time with rapid convalescence, and in over 100 cases among my patients the compound has been invariably successful.

I am, Sirs, yours faithfully,
H. LYON SMITH, M.R.C.S. Eng., L.R.C.P. Edin.
March 12th, 1899.

SURGERY OF PANCREATIC TUMOURS.

To the Editors of THE LANCET.

SIRS,—In the discussion on Mr. Barker's paper at the Clinical Society of London[1] I said that Krönlein had removed a *tumour*, not a "cyst," as reported. It was an angio-sarcoma "as big as a fist." His original communication, with a fine coloured drawing of the post-mortem appearances, will be found in the *Beiträge zur Klinischen Chirurgie*, vol. xiv., 1895, p. 663. A solid tumour of the pancreas, if not left alone altogether, must be taken away, as there can be no question of drainage.

I am, Sirs, yours faithfully,
ALBAN DORAN.
Granville-place, Portman-square, W., March 21st, 1899.

"THE INFECTIOUSNESS OF PHTHISIS."

To the Editors of THE LANCET.

SIRS,—I see that in an annotation in THE LANCET of March 18th dealing with the action brought by the Leas Hotel Company against the executors of the late Radclyffe Hall it is stated that a witness for the defence said that my father, the late Dr. C. E. Fitz-Gerald, had certified the cause of death wrongly. I think it is a thousand pities that I was not called as a witness in the case, as I also saw the deceased once during life, my father having seen him twice, and having ample opportunity to ascertain the nature of the disease I could have positively asserted that in my opinion *my father's* certificate was right and that acute pulmonary phthisis was the cause of death. I have already certified the same for an insurance company and have also carried on a correspondence concerning the disinfection necessary with both the manager of the hotel and also the solicitor to the deceased. It is extremely unpleasant to us to have my late father's certificate impugned.

With regard to a matter appearing in THE LANCET of March 11th, 1899, concerning my late father's paper entitled "The Just Position of Bacteriology," may I be allowed to state that I have no acquaintance whatever with Mr. Maurice L. Johnson and that his letter quoting my father's late paper was entirely outside my knowledge? The paper was my father's last and the view taken was a favourite one with him and I published it out of respect for his memory.

I am, Sirs, yours faithfully,
E. D. FITZ-GERALD, M.R.C.S. Eng., L.R.C.P. Lond.
Folkestone, March 20th, 1899.

MONOPOLIES IN THERAPEUTICAL MEASURES.

To the Editors of THE LANCET.

SIRS,—The letter of Mr. Tallerman which appeared in THE LANCET of March 18th supports only too strongly the grave objection which I have long felt in common with many balneologists in this country to the altogether unnecessary interference on the part of lay inventors in the domain of therapeutics. No department of medical practice is perhaps more open to exploitation of this objectionable character than that presented by balneological therapeutics, but it is only within the past four or five years that we have been confronted by a new and more grave aspect of this evil. Hitherto we have been accustomed to the competition of that large army of unqualified practitioners (male and female) which derives such wide support at the hands of a credulous public, but now we are met by claims on the part of outsiders the character of which will be better realised when the profession has had time to grasp their full significance.

The medical profession, in this country at least, is made up very largely of men who devote a great part of their lives and much money to investigating disease and devising methods for the alleviation and cure of human suffering, and "cursed" in the eyes of his professional brethren would be the medical man who refused to make known any useful discovery or who by patent law or otherwise should limit to his own selfish ends the therapeutic value of any method of treatment whatsoever. Is it tolerable, then, that we should be asked not only to sanction but to support outside the profession practices which we justly condemn within our own ranks? In expressing these views I hold no brief for any particular hot-air apparatus. In truth, although I recognise certain advantages pertaining to each I consider them all to be more or less mere adaptations of principles and methods long known in balneological practice.

In conclusion, and briefly, I would put the case thus. If the medical profession does not possess men sufficiently scientific and inventive to devise suitable and efficient apparatus to carry out its own *methods of treatment* let us at least demand from the outside inventor, as a condition precedent to our recommending or using his apparatus, that he shall apply to it the same principle of free and unrestricted use which we are ourselves in the habit of applying under similar circumstances.

I am, Sirs, yours faithfully,
Buxton, March 18th, 1899. SAMUEL HYDE.

"THE TALLERMAN TREATMENT AND ITS COUNTERFEITS."

To the Editors of THE LANCET.

SIRS,—I have read with surprise Mr. Tallerman's letter in your issue of the 18th inst. ...... In reply to the letter I may safely leave the press and the profession to take care of themselves. With regard to myself I totally deny the suggestion that I was aware of any apparatus at Mr. Tallerman's or elsewhere of a similar character to my own being in existence at the time my patent was granted and in this opinion I am supported by a leading firm of patent agents, who, at my request, made a most exhaustive search at the Patent Office. . ...

I am, Sirs, yours faithfully,
ARTHUR E. GREVILLE.
Upper Berkeley street, Portman-square, W.

⁂ This controversy must now cease in our columns. We omit certain personalities from Mr. Greville's letter.—ED. L.

---

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The General Hospital.

THE present time of the year is one in which the local charitable institutions hold their annual meetings. Prominent among these is that of the General Hospital, the 119th report of which has just been issued. The Board of Management state that the ordinary income in the year 1898 was £15,028, against £11,000 in the two preceding years. The extraordinary income was £7677, against £8050 in 1897, when the proceeds of the Musical Festival amounted to £5000. The number of in-patients last year was 4913 and of out-patients 60,128. The ordinary expenditure was £23,490 8*s.* and the extraordinary £500 19*s.* 6*d.* The report points out that a considerably increased income is necessary to maintain the demands of the new hospital. A systematic inquiry has been conducted into the social circumstances of the patients applying for treatment, the result of which it is promised will be carefully considered; but while it is only right that first aid should be rendered to all cases of accident or sudden emergency, continued treatment should only be given to those who are not in a position to pay for medical attendance. An ophthalmic surgeon, a dental surgeon, and a radiographer have been added to the staff by which additions the usefulness of the hospital will be increased.

The General Dispensary.

The annual meeting of the governors of this institution was held on Feb. 22nd. The 105th report showed that the amount received from subscriptions together with supernumerary tickets was £5452, from investments £879, from donations £1122, and from legacies £1268. The expenditure showed an advance of £374 arising from an increase in the medical staff. The number of patients admitted by ticket was 40,434. The average cost of patients was 3*s.* 10*d.* and a fraction. Dental cases and accidents numbered 7396. The Lord Mayor who presided expressed the opinion that the governors were right in appealing to the suburban districts by their branches, and he deprecated the paying of subscriptions through the Hospital Sunday Fund instead of the ordinary channels.

The Training Institution for Nurses.

The committee in their annual report express their satisfaction in the undiminished activity and usefulness of this institution. They regret to announce the death of Mrs. Diamond who for 23 years had performed the duties of superintendent with the greatest ability. During the year 584 families had been attended. The number of nurses on the staff was 73. The income exceeded the expenditure by £46 and a sum of £100 had been paid to the sinking fund. A separate place for quarantine and a sanatorium was pointed out as a great advantage, as also the addition of a handsome pension fund for nurses who might be disabled after 10 years' service.

A Hospital for Diphtheria.

The advisability of establishing a hospital for the treatment of diphtheria has been the subject of some correspondence with the Health Committee. There is practically no provision in the health equipment of the city for meeting this difficulty and the advantages of obtaining such a hospital have been forcibly pointed out. There is always a reluctance on the part of the authorities to admit such cases into the general hospitals and it is feared some hesitation on the part of nurses to take charge of such cases, not so much from fear of infection and danger to themselves as from the risks of a possible lengthy illness and convalescence. There is said to be accommodation of an ample kind at the small-pox hospital, where the unused part ought to be set aside for such cases. This is a suggestion which demands attention and no doubt will receive the fullest consideration by the Health Committee.

Allegation of Cruelty.

Considerable comment has been made on the action of a police constable who tested the consciousness of a woman who had been assaulted by her husband. The officer in order to ascertain the woman's condition thrust a needle under the thumb-nail of the woman; she did not feel it at the time, but subsequently complained of much pain at the spot. The case was considered by the Watch Committee of the City Council who ascertained that no harm was done though such a test should not have been applied by the officer. The local press express the opinion that they thus justified an illegal act.

March 20th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Children and Epileptics at Crumpsall.

SOME questions interesting to our profession have recently been discussed by the Manchester Board of Guardians. At one of the meetings it was proposed to renew a subscription of 10 guineas to the Cancer Pavilion and Home, and it was stated that "the hospital provided a permanent home for pauper patients who could not be properly treated at their homes," and also "that they could not deal with those special cases at the Crumpsall Hospital." Was it intended that the State hospitals, as they may be called, such as the large and well-appointed institution at Crumpsall, should be relieved of their chronic and incurable cases by sending them to hospitals supported by voluntary subscriptions? As to the ability to deal with special cases at Crumpsall one of the guardians very properly said that they "ought not to detract from the ability of the medical staff," and as a matter of fact the Manchester guardians have for many years past, in addition to their very competent resident medical officers had the advantage of visiting physicians and surgeons of the highest attainments, capable of dealing with any cases coming under their care quite as well as if they were placed in special institutions. The proposal to continue the subscription was lost. At the last meeting of the guardians, Mr. Jenner Fust, the Poor-law Inspector, made some strictures with regard to the accommodation for female epileptics, saying that the yards were very small and got very little sun. As there was land behind he thought that they could be enlarged without any very great expense. It is satisfactory to learn that there has been a considerable decrease in the number of ophthalmic cases and Dr. Reynolds says that it seems to be permanent. In years gone by it was a great scourge among the children at the workhouse. Mr. Fust said it would be very desirable if the whole of the children could be removed from Crumpsall "where the quarters were not the best for children" and were required for other classes. At the workhouse, of course, all the surroundings are pauperising for the children who, if they know no other life, grow up simply to perpetuate the race of paupers. That, indeed, was so throughout the country, but happily better ideas now prevail and more intelligent efforts are made to help them to a less degraded life. The schools of the guardians at Swinton, though of the type now called barrack schools, have been for many years admirably conducted, and Mr. Fust thought that the children should be taken there. He was "pleased to see that the committee had been working in harmony with, and together with, the Society for the Prevention of Cruelty to Children." The chairman of the Crumpsall and the Swinton committees promised that Mr. Fust's suggestions should be carefully considered.

Influenza in Manchester.

Manchester is suffering from a considerable prevalence of influenza and some inconvenience has been caused, it is stated, in factories and workshops and various other places of business. One employer has had 20 per cent. of his workmen away with the influenza and, as he puts it, "other reasons," the disease being the excuse. The many and sudden changes of weather lately have no doubt had a good deal to do with the catarrhal attacks also very prevalent. In these days almost every cold in the head is called influenza, but undoubtedly both what may be called the specific and non-specific catarrhs have caused much sickness. Last week the deaths from all kinds of chest disease were 103 and the week before 92, but it is hoped that the tide will soon turn. But it is never safe to prophesy, and so far as the weather has any influence, that of the last few days has been of a character to justify any of the epithets used in dispraise of March. Salford has fared better than Manchester, Broughton, or Pendleton. Adults have been chiefly affected while children have escaped. At the board schools while influenza has attacked many of the teachers it has spared the scholars. Happily this visitation of the disease is less severe and less fatal than some former epidemics.

The Explosion of Ether at the Rochdale Workhouse.

The recent explosion of ether at the Rochdale workhouse by which the superintendent nurse lost her life and another nurse was very seriously injured is a matter which should be carefully investigated. According to the evidence at the inquest opened on March 14th the surgery is a small room with two doors having spring locks. There was a narrow high cupboard containing "bottles of ether and medicine." One nurse sat with her back to the fire, apparently taking an inventory of the bottles, and the other was counting those on one of the upper shelves, when an ether bottle accidentally fell against another bottle and, "being thin at the neck, broke." There was an immediate explosion, blowing out some of the window glass and setting fire to the furniture and woodwork. The superintendent nurse was found in a semi-conscious state, while the other managed to get out though badly burned. The coroner adjourned the inquest for a fortnight in the hope that the surviving nurse would be able to tell them how the explosion occurred and to give an opportunity for the attendance of the inspector of explosives. The inquiry into this deplorable occurrence will, it is to be hoped, lead to an explanation of the fact that the nurses seemed to have the management of the "surgery" and presumably were allowed to dispense.

Isolation Hospitals.

For some time past a strong feeling has existed in many parts of Cheshire against making what is now considered the necessary provision against epidemic visitations. At Lostock Gralam and at other parish meetings in Mid-Cheshire resolutions were passed the other week "condemning in the strongest terms the attempt of the Cheshire County Council to force upon the Northwich rural district a large and costly isolation hospital for the treatment of infectious diseases." There are wooden structures in existence which were described as adequate for the requirements of the district. The county council have intimated that an inquiry will be made as to the provision of joint or separate hospitals for the Northwich and Winsford urban districts. The question "is provoking much feeling in Mid-Cheshire." The feeling arises probably not so much against sufficient provision being made as from the fear of the extravagant and unnecessary spending of money sometimes indulged in by public bodies.

March 22nd

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh University Court.

AT a meeting of the Edinburgh University Court on March 13th Dr. Andrew Davidson (Edinburgh) was appointed Lecturer on Diseases of Tropical Climates for a period of three years from May next. The Court approved of the arrangements proposed by the Senatus under which Dr. E. W. Carlier should carry on the work of the Chair of Physiology until the end of the current session and also, in conjunction with the additional examiner, the work in connexion with the ensuing examinations in physiology for graduation in medicine and science. The Court, on the recommendation of the Senatus, resolved to institute a lectureship in diseases of the skin and appointed Dr. W. Allan Jamieson (Edinburgh) as University lecturer on that subject. In connexion therewith the Court approved of a recommendation of the Senatus that in addition to the two courses, one of which candidates for medical degrees are required to attend, that there should be a further option of "a course of clinical instruction in diseases of the skin, given by a University lecturer or by a recognised teacher at not less than 20 meetings in the wards of a recognised hospital or in the wards of a hospital and in a dispensary, both recognised for the purpose." At the same meeting intimation was made of a bequest of anatomical drawings to the University by the late Sir John Struthers, Emeritus Professor.

The Chair of Physiology in Edinburgh University.

It is understood that the following gentlemen are candidates for the chair of Physiology in Edinburgh University: Dr. D. Noel Paton, a former assistant of Professor Rutherford and for many years lecturer on Physiology in the Edinburgh Extra-Mural School; Professor G. M. Stewart, Cleveland University, Ohio; Professor Waymouth Reid, Dundee College; Professor Schäfer, University College, London; Professor William Stirling, Owens College, Manchester; and Professor Anderson Stuart of Sydney.

The Edinburgh University Rectorial Address.

On the afternoon of March 14th Lord Balfour of Burleigh delivered the rectorial address to the students of Edinburgh University in the McEwan Hall—the first occasion on which the McEwan Hall had been used for the Lord Rector's address. The proceedings having been opened with prayer, Professor Sir Ludovic Grant, Dean of the Faculty of Law, presented Lord Balfour of Burleigh for the honorary degree of Doctor of Laws. After the degree had been conferred Lord Balfour delivered the address, taking as his subject, National Character and the Function of the Universities in forming the Character and in Preserving, Developing, and Strengthening it. He spoke of the pride which they felt in the national character. They had a right to say, looking back on the past that the nation possessed certain distinctive qualities of which they did well to be proud and in which their pride was an inspiring and not a foolish thing. As a nation they had grown from the age of small things by a cautious courage and a spirit of prudent adventure; they had been ready to hide their differences and to draw closer in moments of common danger; they had adhered to certain ideals, had made their rule over subject nations a synonym for prosperity, and had shown that they could maintain justice as the guiding star in every department of administration. Had they not shown that they were ready "to take up the white man's burden" in every corner of the world, and had they not as a nation striven to recognise their responsibilities? On what did this national character rest? He believed that national character was not a mere instinct or tradition, not only a dominating temperament, but a matter of intellectual and moral discipline to the application of which they must attend and for which they were, each in their own place, individually responsible. He suggested that the foundation of this discipline was to be found in university life rightly understood. Intellectual training was the soundest and most essential foundation for national character. It was a purblind and prejudiced view that looked on the universities as places which are divorced from life's activities instead of the recruiting depôts from which the armies of practical life are to be reinforced.

A Complimentary Dinner to Dr. John Wyllie.

The members of Professor Fraser's clinique at the Edinburgh Royal Infirmary entertained Dr. John Wyllie to dinner on March 16th. Mr. Arthur Preston presided over a company of between 70 and 80. Mr. T. Grainger Stewart and Mr Ramsay Munro acted as croupiers. Dr. Slight and Dr. Gilmour, the resident physicians, were also present as guests. In proposing the health of Dr. Wyllie, the chairman said that in taking steps to have Dr. Wyllie appointed as interim professor of clinical medicine Professor Fraser had never more thoroughly manifested the interest which he took in his students. When Professor Fraser announced that Dr. Wyllie would discharge his duties the announcement was received with acclamation by the large class of clinical medicine. At that time the present generation of students knew of Dr. Wyllie by reputation. They now knew how well earned was that reputation; there was one hour in the day to which they had all looked forward with pleasure, and that was the hour which they spent with Dr. Wyllie. Personal contact with Dr. Wyllie had endeared him to all who had the good fortune to be members of his clinique. The students of Professor Fraser felt themselves each under a personal obligation to Dr. Wyllie for having undertaken the duties which Professor Fraser in his absence had imposed on him. Dr. Wyllie, in replying, expressed the pleasure it had been to him to be once again among medical students whom he delighted to teach and have around him. Professor Fraser's health was proposed by Mr. Bashford. Mr. Munro proposed "The Ward, its Residents and Nurses." Dr. Slight, Dr. Gilmour, and Mr. Stewart replied. The health of the chairman was proposed by Dr. Wyllie. Members of the company provided singing and music and a very enjoyable evening was spent. During the winter Dr. Wyllie has gathered round him the largest clinique in the Royal Infirmary, upwards of 120 men attending. Notwithstanding so large a number Dr. Wyllie's method of teaching has been such that equal benefit has accrued to all.

School of Medicine of the Royal Colleges, Edinburgh.

The number of students attending the classes of the school during the winter session now closing was 1217.

Dealing with the Slums in Aberdeen.

The municipal corporation has now acquired all the property scheduled under the Aberdeen Improvement Scheme Provisional Order which deals with an unhealthy area adjoining Exchequer Row. It has been resolved to take down a number of the dwelling-houses in the interior of the area so as to admit light and ventilation to the narrow, foul-smelling alleys or closes. A large building on the margin, at present used as a private common lodging-house, is to be converted into a tenement dwelling-house for occupants to be displaced by the demolitions and the other common lodging-houses in the area are not to be re-let. There is, however, room for about 125 more lodgers in the recently opened corporation lodging-house in East North-street.

Sanitation in Aberdeenshire.

The reports by the sanitary inspectors of the eight districts of Aberdeenshire for 1898 show that the sanitation of the villages in the county as to water-supply, drainage, and scavenging is, generally speaking, good, and that there is a continued advance in the sanitary condition of workmen's dwellings in the rural localities.

Enforcement of the Vaccination Act in Aberdeen.

At the last meeting of the Aberdeen Parish Council a letter was read from the Local Government Board intimating that the Board was quite unable to countenance the procedure of the council in failing to renew the prosecution of defaulters under the Vaccination (Scotland) Act, and pointing out that before taking extreme measures an endeavour could be made to remove objections by offering glycerinated (and therefore sterilised) calf lymph from the central institution which was conducted under the auspices of the Government. The parish council resolved that in purchasing lymph from the central institution the council should obtain a guarantee that the lymph was pure and would produce no injurious effects, so that medical officers might be in a position to certify the quality of the lymph to those objecting to vaccination, and that consideration of the Board's letter be deferred till a reply was received.

St. Andrew's Ambulance Association.

This association which has centres in various towns of Scotland has now been incorporated by Royal charter.

Inter-University Athletic Sports.

It is stated that sports have been arranged between the Universities of Glasgow, Edinburgh, and Aberdeen, and that the first meeting will take place in Aberdeen in May or June next.

March 22nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons in Ireland.

MR. MCARDLE of St. Vincent's Hospital recently made an accusation of religious partiality and bigotry against the Royal College of Surgeons in Ireland in an address which was published in the morning papers. The *Irish Times* of March 20th contains a reply and refutation in the form of a letter signed by the four Roman Catholic members of the Council of the College. This communication quotes what Mr. McArdle is reported to have said—viz.: "That out of the numerous class of Catholic students, many of them distinguished, it has failed to select one to occupy any position of trust or emolument. Occasionally a paltry examinership is offered to some safe gentlemen for spite and the Council has thrust upon it or absorbs a unit from the body to which we belong." The letter points out that in addition to four Catholic members of Council elected by the College there are three examiners elected by the Council all professors in the Medical School of the Catholic University—namely, Dr. Birmingham, Dr. Coppinger, and Dr. Smith. It regrets that up to the present there is no Catholic Professor in the College, but makes the remark that as an indication of the liberal temper of the College of the three candidates who were recently nominated for commissions in the Royal Army Medical Corps two were Catholics. The above letter was signed by Mr. Meldon, Mr. Lentaigne, Mr. Chance, and Dr. Cranny. Mr. McArdle's accusation has fallen flat, for he had the honesty to mention that he himself was a rejected candidate for an examinership in the College. It had, however, the effect of eliciting a letter from Mr. Myles, the Vice-President of the College, and a leading article in the *Irish Times*, as well as the letter just described, all in defence of the College.

Mater Misericordiæ Hospital, Dublin.

The following appointments were made on March 16th: Martin Dempsey, M.D., M.R.C.P. Irel., to be physician; and John O'Donnell, M.B., B.Ch. R.U.I., to be assistant physician. Arrangements are being made to establish a convalescent home in connexion with this hospital, now the largest clinical hospital in Ireland.

The Death-rate of Belfast.

The present Lord Mayor of Belfast (Mr. Otto Jaffe) has frequently drawn attention to what has been the universally admitted low estimates made by the Registrar-General (who lives away from Belfast in the atmosphere of Dublin) of the population of Belfast. According to the census in 1891 the inhabitants of the city numbered 255,950, but since that date the population has gone on increasing, so that now the Registrar-General calculates the death-rate on an estimated population of 308,960. The city accountant of Belfast estimates the present population as at least 356,184 and he arrives at this figure by allowing 4·40 persons to each of the 80,951 ratings in the city, the census returns of 1891 showing that there were 4·75 persons to each rating, and the Belfast city accountant reduces this 4·75 by 0·35 for vacancies and so arrives at his estimate. When recently in Dublin the Lord Mayor interviewed the Registrar-General on the subject and he undertook to reconsider the matter if he could have an authenticated return of the vacant houses which had lately been quoted by certain Dublin newspapers as from 12,000 to 14,000. As a result the Belfast police on March 13th took a census of the vacant houses and found only 5540. The reasons for there being these vacant houses are that a number are built during the winter when general employment is scarce and these are not occupied until May. Again, many houses are calculated in this number which are not quite finished, being without gas-fittings or water-pipes, and there is also a desire to abandon the old class of houses which have not yet had their sanitary arrangements remedied. Further, there is a tendency, owing to the extension of the tramway lines, to live further away from the centre of the city. As a result of this house census it turns out that the Lord Mayor's estimate of from 358,000 to 360,000 as the population of Belfast is not far from the mark, but if even the figures of the city accountant (356,184) are adopted by the Registrar-General instead of his own calculation, 308,960, it will completely alter the health statistics of Belfast, and show that the published death-rate is much too high. The whole discussion shows that statistics give anything but safe conclusions unless there can be no question of the correctness of the figures.

The late Dr. OHara of Ballymena.

At a largely attended meeting of the friends of the late Dr. O'Hara held in Ballymena on March 15th it was decided to inaugurate a fund, to be called the "Dr. O'Hara Memorial Fund," with the object of perpetuating the memory of the late Dr. O'Hara in Ballymena and the surrounding district where he practised. A large sum has already been subscribed

Irish University Education.

It is generally thought here that after the Duke of Devonshire's speech last week so far as the existing Government and the present Parliament are concerned the Irish University question will not be touched and that Mr. Balfour's promised changes will for a time be postponed. Two reasons for this course are assigned—first, the anti-ritualistic wave which is said to be passing over England and, secondly, the failure to come to a clear and definite agreement with the Roman Catholic hierarchy in Ireland. It was that body which left Mr. Gladstone in the lurch when he tried to settle the question in 1873 and it is said that Mr. Balfour was determined that until he got a clear and definite pledge from them that they accepted his solution of the question as final he would not attempt to advocate the question any further. Irish university matters are now in a worse condition than ever. All parties are dissatisfied with things as they are and yet when an attempt is made to come to a settlement there would seem to be much opposition from some as well as apathy on the part of others who are calling out most loudly that there must be a change.

The Prevention of Consumption.

The Lord Mayor of Belfast having received requisitions signed by a large number of members of the medical profession as well as by representative ratepayers of the city has convened a public meeting of the citizens to be held in the Town-hall on Tuesday, April 4th, to consider the desirability of taking steps to form in the city a branch of the National Association for the Prevention of Consumption and other forms of Tuberculosis. Sir William Broadbent, Bart., M.D. Lond., is coming to speak at the meeting.

The Nursing Circular of the Local Government Board.

The recent circular issued by the Local Government Board requiring nurses to be trained in clinical hospitals is causing considerable discussion and bad feeling. Dr. J. O. Hall, J.P., surgeon to County Monaghan Infirmary and medical officer of the Monaghan Workhouse Hospital, having been requested by the board of guardians to state his opinion of this nursing circular did so fully and freely as a man of his thorough independent character would be expected to do, whereupon the guardians received a letter from the Local Government Board in which they declared that they communicated with Dr. Hall who admitted that his observations as formulated by the clerk of the union were correct. The Board go on to say that "they consider it would be subversive of all discipline in the Poor-law service if the officer who is bound to conform to the regulations was permitted with impunity to use language the object of which is to encourage resistance to the orders issued for the guidance of the local authority and its affairs. In the case of an officer of Dr. Hall's rank and standing the offence is particularly serious and in the event of its repetition would lead the Local Government Board to consider whether he was any longer fitted for the position of medical officer of the workhouse." It need hardly be said that this threat of the Local Government Board to instantly dismiss a man of Dr. Hall's position should he on any further occasion dare to express an opinion adverse to any circular which they may formulate is deeply resented by the medical profession.

The Glenties Medical Libel Action.

This case which has occupied several days in hearing at the county Donegal Assizes in Lifford concluded on March 20th. It was an action brought by Mr. Kelly, dispensary medical officer, Glenties, against the proprietor of the *Londonderry Sentinel* and two members of the Glenties Dispensary Committee for libel against all three and for conspiracy against the two latter, the other defendant having been struck out of the count for conspiracy. The whole matter, as the judge in his summing up pointed out, turned on the question whether a resolution (accusing the medical officer of neglect of duty) which formed the subject matter of the alleged libel was not duly passed at a certain dispensary meeting, but was "hugger-muggered" through after the ordinary business and sent to the *Sentinel*, and that it was for the jury to say, the judge pointed out, whether there was a conspiracy on the part of the two members of the Dispensary Committee. The judge said he could not see how the apology which had been made by the editor of the *Sentinel* could be fuller. The jury found for the medical officer as against the two members of the Dispensary Committee and awarded £100 damages on each count, and found for the defendant, the editor of the *Londonderry Sentinel*. They held that there was negligence but not gross negligence in the publication of the resolution complained of.

The Holidays of the Irish Poor-law Medical Officer: A New Rule.

A circular was received by the Cork Board of Guardians from the Local Government Board intimating that in future Poor-Law medical officers will be entitled to a month's annual holiday and that substitutes must be paid by the guardians. One of the guardians present at the meeting

be obliged to pay £350 a year for medical substitutes and whilst he did not object to their medical officers getting a holiday he considered that the guardians ought to have had some previous intimation on the subject in order that the financial aspect of the question might be adequately discussed. He then pointed out that if the order had been issued in the year 1897 half the £350 would have been paid by Government, but now the total sum must come out of the local rates. Other guardians took the same view and a resolution was unanimously adopted calling on the Local Government Board to provide half the cost of the substitutes for the medical officers of the union. It was also decided to forward a copy of the resolution to all the other boards of guardians in Ireland with a view to concerted action. It must be satisfactory to the medical officers to find that it was to the incidence of cost and not to the principle of paying the substitutes that the guardians objected.

A Homicidal Lunatic.

Last week a terrible tragedy was enacted in Kerry. A young man named O'Donnell became suddenly mad, belabouring his mother till he had reduced her head to a pulp. He then threw her out on the road and rushed off in a half-nude state, attacking everyone who chanced to come in his way. One of his victims hurried to a police station for assistance and fortunately the constables were soon able to grapple with the unfortunate man and prevent him from doing further mischief. He was promptly transferred to the Killarney Asylum and it is stated that this is the third occasion on which it has been found necessary to commit him there. Two years ago when living on a small island he armed himself with a pitchfork and attacked the other islanders who were obliged to barricade their houses. He has been under restraint during the past eight months and was regarded by his relatives as quite recovered. Now an important question for the general public, and no doubt an anxious one for medical superintendents of asylums, is—how should lunatics with homicidal tendencies be dealt with during what may prove to be mere lucid intervals? On the one hand, are they to be permanently deprived of their liberty and maintained by the ratepayers? and, on the other hand, must those residing in their immediate vicinity look forward to the possibility of being at any moment butchered in cold blood?

March 22nd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Wounds of the Abdominal Wall with Extrusion of Intestine.

AT the meeting of the Society of Surgery held on March 1st sundry cases of successful operation for wound of the abdomen with extrusion of the intestines were narrated. M. Regnier showed a patient upon whom he had operated for a wound of the abdominal wall accompanied by extrusion of one metre of intestine and this perforated in three places. He drew a comparison between this case and that of a woman upon whom he had also operated successfully for extrusion of the intestine through the ruptured scar of an umbilical hernia. M. Bazy related a successful operation by M. Faure for a wound of the abdomen with protrusion of two metres of intestine. M. Tuffier related the case of a patient operated on by his house surgeon for a gunshot wound in which the gut was perforated in eight places. M. Pozzi referred to a case in which a sudden hernia took place in a woman who had been quite recently operated upon by laparotomy. Her recovery was as equally uneventful as in the other cases cited.

The Campaign against Pulmonary Tuberculosis amongst the Poor.

Dr. Latulle, physician to the Boucicaut Hospital, who has already tried in his wards experimental isolation of tuberculous patients and who has for some time past strenuously advocated the erection of sanatoria for tuberculous patients, has published an article dealing with the whole subject which has excited much attention. In this article he enters an earnest protest against the slowness with which the Assistance Publique deals with the reforms so necessary in the matter. He criticises severely the system which obtains in the Paris hospitals of setting apart wards for tuberculous patients, a system productive of no good results, inasmuch as those actually dying from tuberculosis are herded together with those in whom the chance of recovery is by no means remote. It is impossible to treat this last class which is by far the most important and the numbers of which Dr. Latulle estimates at from 3000 to 4000 per annum in the manner so necessary for their condition without removing them from the middle of the town. Dr. Latulle sums up his conclusions very neatly as follows. He would have special wards in the hospitals for the incurable cases of tubercle, for in such cases the hygienic treatment is useless and if carried out would represent an enormous expense quite out of proportion to the good which might accrue in possibly an exceptional case. Further, for such tuberculous patients as offered a chance of cure and were either unwilling or unable to leave Paris he would have small wards built where the treatment by air, rest, and feeding could be begun and carried on during the time that the patient was being urged to go to one of the country sanatoria. For the building and maintenance of these last he would allot the greater part of the money now spent upon prophylaxis—although this has its uses—and upon treatment. At the present moment there are no sanatoria in France such as exist in other countries for the use of the poor who suffer from tuberculosis. Except the convalescent homes for tuberculous children which do a great deal of good there is but one sanatorium actually at work in France—that at Cimiez, which makes up 20 beds. At Lyons the Hauteville Sanatorium has just been built and is on the point of being opened. It contains 100 beds. At Amiens, Havre, Rouen, and Orleans such buildings are only in the projection stage. Paris has her sanatorium at Augicourt which has cost an enormous sum, the money to pay which has yet to be found. It contains 300 beds and although finished two years ago has not yet received a single patient. The expense of keeping up the place is a terrible lesson for the administration of the Assistance Publique. For the future it is intended to build only small sanatoria but many of them, and the actual buildings are to be put up as cheaply as possible so as to supply more beds. Unhappily, the generous sacrifices made in France for the carrying on of the warfare against tuberculosis have been mainly expended upon architects and builders and, as at Augicourt, there is no money left for the patients after the buildings have been erected.

The Treatment of Tetanus by Intra-cerebral Injections.

At the annual meeting of the Society of Surgery held on March 8th, M. Quénu read the notes of five cases of tetanus treated by intra-cerebral injections of tetanus antitoxin. The first case, which had been under the care of M. Beunier, was that of a woman, aged 48 years, in whom tetanus developed eight days after the infliction of a wound. Chloral, morphia, and lumbar puncture were all tried in order to relieve the spasms but in vain. Recourse was therefore had to intra-cerebral injections, but the patient died. The second case was that of a young girl in whom the injections were used some days after the onset of the disease. She died also. M. Quénu mentioned three other cases, in all of which a fatal result occurred. On the other hand, he felt bound to mention that M. Villon had reported two cases in which cure had followed treatment by injections both intra-cerebral and subcutaneous. M. Quénu concluded by saying that the prognosis in a case of tetanus was most uncertain. According to M. Peyrot and M. Berger good results have been obtained from excision of the focus of infection. M. Chaput and M. Ricard have each reported a case of death after intra-cerebral injections. M. Lucas-Championnière said that no treatment could be definitely recommended. He had seen patients with tetanus die after amputation and others recover. If a case turned out badly it was not right to blame the medical man for having pursued one course of treatment rather than another. The curative value of either amputation or the use of serum was still far to seek.

Notes on News.

M. Napias, the head of the executive department of the Assistance Publique in Paris, has made it known to the public that the out-patient departments of the hospital will in future be available on Sundays and holidays. As on ordinary days the doors of the out-patient department will be open from eight o'clock in the morning until nine. The doors will then be shut. The new regulations will come into force on Sunday next, March 26th.

Dr. Durand Fardel died on March 20th from pneumonia at the age of 48 years. The deceased was a member of the Academy of Medicine and an inspector of the State mineral water-springs. He has done very good work and was a Chevalier of the Legion of Honour.

(FROM OUR OWN CORRESPONDENT.)

The Utility of Gargling.

THE utility of gargling in diseases of the throat has been denied by several observers, as, for instance, by Dr. Kantorowicz. Gargles nevertheless continue to be prescribed by the majority of medical men and constitute one of the principal methods of treatment in those cases. In order to ascertain whether there are valid reasons for maintaining this practice Dr. Sänger has made some experiments the results of which he has published in the *Münchener Medicinische Wochenschrift*. He points out that the therapeutic utility of gargling depends on whether the fluid employed reaches the pharyngeal mucous membrane and the tonsils or not, and for the purpose of arriving at a definite conclusion he brushed the tonsils of a patient with methylene blue and made him afterwards gargle with water. In the result the water when rejected from the mouth was colourless, neither was there any blue tint visible in the interior of the mouth although the tonsils continued to be intensely blue. Obviously, therefore, the fluid had not reached the tonsils. The same result was obtained in every instance. In another series of experiments the velum, a portion of the tongue, and the tonsils were dusted with wheat-flour, after which the person made use of a gargle consisting of a solution of iodine in glycerine, the consequence being that the velum and the tongue showed the blue colour of starch acted on by iodine, whilst the flour on the tonsils was neither coloured nor washed away. Dr. Sänger therefore concludes that gargling is useless and that where this kind of local treatment is indicated it would be better to swab the pharyngeal mucous membrane with pieces of cotton wool, avoiding brushes, which are liable to injure the mucous membrane.

Operative Treatment of Pulmonary Gangrene.

Professor Körte, surgeon to the Urban Hospital, recently exhibited before the Berlin Surgical Society a patient on whom he had operated for gangrene of the right pulmonary apex. The man was 32 years of age and became ill five weeks before with pyrexia, cough, and fetid expectoration. As the disease progressed considerable fragments of the lung were coughed up and a large cavity in the right apex was recognised by percussion. The patient was accordingly admitted into the surgical department of the hospital and an operation was performed. A large circular incision was made under the clavicle extending to the axilla and a piece of the second rib was resected. The pleural cavity was found to be obliterated. There was a stratum of normal tissue one centimetre (0·4 inch) in thickness and then the thermo-cautery penetrated into an extensive cavity filled with putrid material. A large pulmonary "sequestrum" was situated at the entrance of the principal bronchus. The patient made a comparatively quick recovery and his lung now contains a large cavity with a healthy granulating surface.

The Balneological Societies.

The congress of the Balneological Societies was opened on March 3rd, Professor Liebreich being in the chair. The first address was delivered by Professor Klemperer on dietetic methods followed at health resorts. Dietetic treatment at mineral water health resorts was, he said, essentially the same as at home, being modified only by the chemical or physical qualities of the springs. A patient suffering from obesity ought to live at home in the same way as in Marienbad, eating and drinking in moderation, but not necessarily according to precisely formulated rules. The quantity of food must, of course, be diminished, especially the amount of fat and carbohydrates, and abuse of alcoholic liquors must be forbidden. Too prompt a reduction of weight may be followed by nervous troubles. In gout there are not as yet scientific data on which to found standards of diet, the causes of the disease not being completely known. Generally a vegetarian regimen is to be recommended, but in a certain number of serious cases it is essential to maintain the patient's strength by the use of a mixed dietary.—Dr. Immelmann discussed the diagnosis of pulmonary tuberculosis by means of the Roentgen rays. The rays in passing through the normal lung filled with air do not cast a distinct shadow on the fluorescent screen, but pulmonary infiltrations give rise to a comparatively deep shadow. With a series of patients suffering from pulmonary catarrh a shadow was obtained on the screen and after four months the patients were found to be phthisical. In another series of cases where the lungs on transillumination gave no shadow the patients were all found to be in good health after the lapse of four months. The Roentgen rays may therefore be useful in diagnosis under certain circumstances.—Dr. Schuster of Nauheim exhibited skiagrams of patients with heart disease.—Dr. Sarason of Hamburg described Finsen's treatment of lupus by exposure to electric light which has an irritating and bactericidal action penetrating to the deeper strata of the skin. The published results showed 146 cures among 296 patients; 84 were still under treatment. The average duration of the treatment was four months.—Professor Liebreich read a paper on the strong defensive power which the cells of the human body are capable of exerting against micro-organisms as proved by the researches of Metchnikoff. The healthy and vigorous cell is able to destroy the bacteria or to immure them as in pulmonary tuberculosis. It must therefore be the aim of rational treatment *to strengthen the cells, so that they may be competent* for this duty, and with this object all available means, dietetic, physical, and pharmacological, must be applied.—Other papers related to winter health resorts on the Baltic, to terrain cures (i.e., walking uphill), to cyclo-therapy, and to the treatment of syphilis in mineral water health resorts.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Tragedy in the Siena School: Suicide of Professor Cantieri.

THE Nestor of the Sienese medical faculty, Dr. Alessandro Cantieri, Professor of Clinical Medicine in the local university, one of the most esteemed consultants and teachers in the Italian kingdom, committed suicide with a rifle at 11 A.M. on March 14th. He was found dead sitting in his armchair in his private room. He had one foot bare, having doubtless tried to draw the trigger by its means, but not having succeeded with this he availed himself of the walking-stick with curved handle which lay beside him. The explosion must have taken effect instantaneously, as the cranium was horribly shattered, while, strange to say, no detonation was heard even by his servant who entered the room a few minutes afterwards to announce a visitor. Two letters lay within reach—one open, one sealed—both of them addressed to his *daughter who kept house for him. In the open letter* he declared himself weary of life through having incessantly to pay debts contracted by relatives, while he could no longer at his advanced age (78 years) earn the income by which he could have met these demands with ease. In a postscript he added: "Non sono pazzo. Conosco e so pienamente quello che sto per fare" (I am not mad. I have full understanding and knowledge of what I am about to do). For the rest of the day and for all the day following the University was closed in token of sorrow and respect for the deceased. And so disappears from the Italian professional world a familiar and ever-welcome figure, particularly at the periodical congresses, national and provincial. A son of Siena, from his boyhood upwards he was educated at her schools, preparatory and final. Medicine was the calling of his early choice and after a thorough course in the Sienese class-rooms and cliniques he proceeded to Florence and put the finishing touch to his qualifications at the Istituto di Studi Superiori. He graduated in 1844 and thought it best to go at once into general practice as conducing to the consultant's most profitable training and laboured for some years as "medico condotto" (salaried medical officer) at Castelnuovo Berardenga and at *San Gemignano. He never regretted this experience. On the contrary,* he congratulated himself on the practical resource and self-reliance which it gave him when he passed from it to the medical clinique of Professor Burresi in the Sienese University to whom he acted as assistant. His rise was now rapid. For some years he held the chair of *special medical pathology and from this he* was *promoted* to that of general clinical medicine of which he continued to his death "professore ordinario." He was a steady, indefatigable worker, discharging the duties of his class-room and clinique with "conscientious alacrity," while in private practice he acquired a numerous *clientèle* by his judgment and skill. As already stated, he was a frequent attendant at the professional congresses, seldom intervening without making them memorable by some original or suggestive memoir or by some acute and impartial while always perfectly courteous criticism. In 1894 he celebrated the jubilee of his graduation in medicine and the occasion evoked an extraordinary demonstration of loyalty *and affection from grateful pupils at home* and abroad. To the last he kept in the closest touch with the University and though by weight of years compelled to drop the bulk of his practice he never failed to appear with the old punctuality in the class-room or the Istituto Anatomico. In fact, on March 13th, at 11 A.M., just 24 hours before his death, he assisted in the Istituto at the necropsy of a woman who had died in his clinique. Of such a man, lost to life, to science, and to the profession in a manner so tragic, the funeral obsequies could not fail to be impressive. Not only the University, as stated, but all the scholastic institutions of Siena were closed for the day, and the Faculty of Medicine undertook at its own expense, aided by the Minister of Public Instruction *(Baccelli), who contributed 400 fr., to make the "last scene* of all" worthy of the deceased. The hearse was followed by the entire University staff, professors, private lecturers, and assistants; by all the practitioners of the city and many of the province; and by the students bearing a banner draped in black and two crowns, one in the name of the undergraduates of *all faculties, the other in the name of* those of the fifth and sixth medical years—the bulk of them members of Professor Cantieri's class and clinique. The *personnel* of the various hospitals and charitable institutions came next; then a long train of carriages, the whole route being lined with the public, all of them lifting hats respectfully as the procession passed on. A pause was made under the "loggiato" or porticoed gallery of the Convitto Nazionale Tolomeo and funeral orations were pronounced by the Rector of the University, Professor Barduzzi, by Professor Falaschi as spokesman of the medical faculty, and by various other orators representing the many interests—professional, municipal, and charitable—with which the deceased was more or less intimately associated. Thereafter the procession resumed its march till it reached the Cimitero Comunale in which Professor Cantieri had expressed a wish to be interred.

March 18th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Federal Quarantine.

AT the Federal Council sitting in Melbourne in January a Bill was introduced dealing with federal quarantine, to come into force "when and so soon as the Governor of New South Wales notifies to the *Governors of Victoria, Queensland,* and Western Australia, that the *Government of New South* Wales formally agrees to contribute under the provisions of the Act a proportionate part of the expenses connected with its execution." The prime object of the measure is to secure uniformity in quarantine administration in all the colonies and to apportion the cost of maintenance on the basis of population. The difficulty is that New South Wales has not joined in the scheme and until it does Victoria will have to bear the chief portion of the expense. In the Council the Bill passed its first and second reading *pro forma*, on the understanding that its consideration in committee should stand over. The Bill proposes to appoint "federal health officers" with headquarters at Thursday Island, Albany, Adelaide, and Palmerston. The salary and tenure of the appointments are to be fixed by the Governor in Council of the colony concerned and the holders of the appointments will be allowed private practice. The officers are to inspect every vessel arriving in port from "beyond sea"—i.e., outside Australian waters—and a list of questions to be put to masters and ship surgeons is specified.

Presidential Address.

Dr. R. B. Duncan, the retiring President of the Medical Society of Victoria, took as the subject of the customary valedictory address, "Wound Treatment, Past and Present." He reviewed the changes in the treatment of wounds during the last 30 years and pleaded for greater uniformity in the application of the principles of antisepsis and asepsis. He deprecated the growing custom of using dressings, sutures, &c., just as they leave the hands of the wholesale manufacturer. While asepsis was the ideal, there were so many difficulties in its practical attainment under ordinary conditions that the mixed method was the safest. He strongly urged the necessity of frequent bacteriological examinations of the dressings, sutures, ligatures, and scrapings from the hands of surgeons and nurses and of the discharge from the wound. The early detection of infection and the prompt use in such cases of antitoxins, according to the nature of the infection, would lead to a diminished mortality from tetanus and septicæmia. Dr. Duncan further insisted upon the necessity of manufacturing antitoxins and protective serums in Australia, where the scanty and precarious supply and almost prohibitive price of these agents seriously interfered with their proper use. The address concluded with a warm panegyric upon Lord Lister, "the greatest benefactor of the human race so far as the saving of human life is concerned."

Death of Sir Alfred Roberts.

Sir Alfred Roberts, Kt., M.R.C.S. Eng., L.S.A. Lond., died on Dec. 15th, 1898, at the ripe age of 75 years. His life was one of constant and successful effort to realise a high ideal as a cultured gentleman and a high-minded practitioner. Hi name is identified with the Prince Alfred Hospital, Sydne which will ever be a monument to his zeal and assiduity. his action when a member of the Board of Health wa also due the construction of the Little Bay Hospital for Infectious Diseases. He was born in London and he completed his medical course at Guy's Hospital. He arrived in Sydney in 1854 and rapidly acquired an extensive practice. He was soon appointed one of the surgeons to the Sydney Infirmary, a position he held for 18 years. During that period he organised the nursing arrangements and introduced the training of nurses, a plan soon followed in the other colonies. He was examiner in medicine at the Sydney University and honorary secretary to the Prince Alfred Hospital.

Appointments.

A rearrangement of posts in the hospitals for the insane in Victoria has been made. Dr. McCreery will henceforth act solely as inspector-general and is relieved of the charge of the Kew Asylum and Mr. Beattie Smith has been transferred from Ararat to Kew as superintendent. Mr. Barker goes from Ballarat to Ararat and Dr. Lethbridge goes to Ballarat. Mr. Godfrey becomes senior medical officer at Kew and Dr. Steell at Yarra Bend. Dr. R. H. Todd has been appointed deputy coroner in Sydney in place of Dr. Rennie. The new deputy coroner is a barrister-at-law as well as a doctor of medicine. Dr. Mary Vaughan Cowan has been appointed assistant surgeon to in-patients at the Children's Hospital, Melbourne.

Feb. 1st.

NEW ZEALAND.

(From our own Correspondent.)

Annual Meeting of the New Zealand Branch of the British Medical Association (concluded from p. 734).

A meeting of the Council was held on Jan. 4th, 1899, in the University Buildings, Auckland. Present: Dr. Pollen (representing Wellington), Dr. Gibbs (Nelson), Mr. Fleming (Otago), Dr. Pabst and Mr. Dawson (Auckland), Dr. Mason and Dr. Cleghorn (Canterbury), Dr. Fell (President of the Branch), and Dr. Scott (President-elect), who took the chair. A considerable amount of correspondence and accounts were gone into and dealt with, among which was the notification that the Hawkes Bay Section had disbanded from the Branch. Another matter introduced by Dr. Gibbs (Nelson) was a subject to which I have frequently referred in these columns—viz., the resuscitation of the *New Zealand Medical Journal*. The fact is now being recognised that it was a misfortune that the journal was ever allowed to collapse. In reference to this matter Dr. Gibbs said that a year ago a recommendation was sent from the Nelson Section to the Council in Wellington that the association existing between the New Zealand Branch of the British Medical Association and the *Australasian Medical Gazette* should be dissolved and that the New Zealand Branch should resume the publication of their own journal, and he asked if any reply had been sent to that recommendation. The general secretary informed him that no reply had been sent. Dr. Gibbs then pointed out that the *New Zealand Medical Journal* had cleared expenses and fully paid its way. They had now had two years of the *Australasian Medical Gazette* and the second year showed that the circulation had decreased. The general secretary explained that during the first year it was obligatory on members to take the *Gazette* while it was not so during the second year and consequently the circulation had fallen from 170 in the first year to 105 in the second year. The Nelson Branch notified that they intended to give notice of a motion that the *New Zealand Medical Journal* should be resuscitated under the auspices of the New Zealand Branch of the British Medical Association. Dr. Fell stated that he had spoken to Dr. Barnett about the editorship of the *Australasian Medical Gazette* and that Dr. Barnett had informed him that he intended to place his resignation in the hands of this meeting because he felt that he had not received the support which he might have expected from members of the profession practising in the colony and he thought perhaps that somebody else ought t ndertake the duties pertaining to the office so as to it a success if possible; but nevertheless he would be continue his editorship of the *Gazette* if it should h of the meeting. It was then resolved: "That this nowledges its indebtedness to Dr. Barnett for his f the *Australasian Medical Gazette* and requests inue his editorship pending the consideration of a notice of motion given by the Nelson section to the effect that the *New Zealand Medical Journal* should be resuscitated." This is as it should be; it is high time that we had our own journal again. Medical men practising in this colony can interchange ideas and keep records of their own individual work and experience far better by means of a journal published in this colony than by one published in Australia. The original *New Zealand Medical Journal* was, in my opinion, a decided success when it was edited and published in Dunedin. Surely there are men capable and energetic enough still among us to undertake the task of editor.

Dr. Saunders (Wanganui) attended before the Council and explained the position of the Hagey and similar institutions in New Zealand. In the course of his remarks he said that it appeared to him to be necessary for some medical man to come before the Council with the object of endeavouring to prevent members of their profession from "covering" in any shape or form a body of unqualified persons. As soon as these people—he referred more especially to the Hagey Institute—were exposed in one part of the colony they obtained a fresh footing in some other town and by means of advertisements for the bichloride of gold treatment for narcotism and alcoholism they succeeded in establishing a syndicate and did a great deal of harm. Lately, during November, there were two cases of sudden death in his district, both of the deceased having been recently subjected to this bichloride of gold treatment for alcoholism. In one case—a case of suicide—he was called by the police to see the deceased and in the course of the investigation before the resident magistrate the fact was elicited that the people who ran this bichloride of gold cure for drunkenness made the astounding statement in court that *they in every case had a medical certificate sent by a duly qualified medical man as to the health of the individual before he was subjected to the treatment.* He said that astonished him very much and he told the magistrate in court that he knew that that proceeding was altogether unorthodox and contrary to the ordinances of the profession and if he knew of any medical man who covered them in that way he would report the matter to the proper authorities. He did not desire in any way to individualise any person or persons but he merely came before the Council with the object of seeing what could be done to stop these proceedings on the part of medical men in the future. It would not be necessary for him to go into the whole story of the bichloride of gold cure for drunkenness, how it originated in America about 25 years ago, and how an attempt was made to thrust it on the English market. He thought that great credit was due to the action of the Society for the Study of Inebriety and to the Temperance Society of London for their action in regard to this matter. The Lancet in 1892 published a vast amount of most instructive information concerning the

Resolved: That the subject be referred to the general meeting with the recommendation that a notice be sent to all the medical men in the colony advising them that the Council intend referring this subject to the General Medical Council in London should any case come before their notice of a member of the profession attaching himself to such an institution.

Dr. Mason (Otaki), our Parliamentary representative, announced that the Government was now prepared to import serum in bulk. It would go to Wellington and on application any medical man could have a supply of it. Further, if any medical man sent pathological specimens for examination they would be reported on free of charge. It is intended, too, that tubes of culture media for ordinary diseases are to be forwarded to all medical men on application—they would be placed in the hands of the local officers in the various districts of the colony. It was suggested, too, that the Government should appoint an officer in the large centres to whom the medical men would be able to return their tubes for report. The media developed at blood heat so that there was no difficulty in cultivation. It was resolved that a hearty vote of thanks be tendered to the Government for its action in reference to this subject.—Dr. Fell in supporting this motion drew attention to the fact that it was solely due to Dr. Mason's energy and tact that they were enabled to thank the Government for such advantages.

On Jan. 5th Dr. Mason read a very interesting paper on Malignant Œdema; Amputation at the Thigh; Recovery. The paper was illustrated by the author's cultures of the bacillus which were well portrayed. Dr. Truby King followed with a paper on the Scientific Feeding of Calves, and in a very interesting lecture he demonstrated how the weight of the calves depended on the manner in which they were fed. This is a subject of the highest importance seeing that now public attention is being directed to the desirableness of preventing the spread of bovine tuberculosis.

On Jan. 6th Dr. Macgill showed with great success the practical Widal test for the diagnosis of enteric fever. It was a very interesting demonstration. Dr. Pabst followed with some valuable remarks on the same disease from a clinical aspect and Mr. Baldwin gave a series of statistical tables showing the actual number of cases of enteric fever treated in the Auckland Hospital for a long series of years past. It was evident to all present that Mr. Baldwin (the resident surgeon to the Auckland Hospital) had taken immense pains with this subject and illustrated as his tables were by excellent diagrams the result of his work should be found in the future a very valuable record for the hospital archives. It is evident that the Auckland medical men have had their attention of late directed very closely to this disease for Dr. Macgill followed with some excellent remarks on the same subject from a bacteriological point of view. That the Auckland Hospital itself is far in advance of what it used to be is a certain fact. It is clean, well managed, and well provided for in all details. Its general surroundings are in marked contrast to what existed only a few years ago when, in my opinion, it was anything but a model institution.

On Jan. 7th it had been arranged to wind up the annual conference by means of a harbour picnic. An Auckland Harbour picnic is a thing to be remembered—the beautiful scenery, the splendid fishing, and the kindly hospitality of the Aucklanders being well known to me personally; but this year it was not to be, for a real change was in store for the visiting members of the profession. The Government granted in a very generous manner a special trip to the world-famed sanatoria of Rotorua to all members of the profession attending the conference. The trip was to be free of cost and two special carriages were supplied. About 40 members of the profession took advantage of this kind offer and one and all enjoyed themselves greatly. There can be no doubt whatever that the present Government of New Zealand, although accused on a great many counts, cannot be indicted by the medical profession for not answering to any "knock at their door" for assistance when required, the Premier (the Hon. R. J. Seddon) being the first on all occasions of medical conferences to do whatever is possible to further our discussions and to render our stay, wherever the rendezvous may be, pleasant and satisfactory to all concerned.

Feb. 3rd.

Obituary.

DEPUTY INSPECTOR-GENERAL JOSEPH JEE, V.C., C.B.,

HONORARY SURGEON TO THE QUEEN.

DEPUTY INSPECTOR-GENERAL JOSEPH JEE died at his residence, Queniborough Hall, near Leicester, on March 17th. He received his education at the Universities of London and of Edinburgh and also at the École de Médecine at Paris. In 1842 he joined the 1st Dragoons as assistant-surgeon and became surgeon in 1854. Eight years later he was appointed surgeon-major and subsequently he retired with the rank of honorary deputy inspector-general in 1868. During these years he saw much service. For his conduct in the Persian War of 1857, including the night attack and battle of Kooshab and the bombardment of Mohumrah, he received the medal with clasp. He served with Havelock's column in the several actions leading to, and ending in, the relief of the Residency of Lucknow and its subsequent defence, ending in the final capture of Lucknow. He was present with Brigadier Campbell's column in the affairs of March 20th and 21st, and also in the Rohilcund campaign in 1858 and the capture of Bareilly, receiving the medal with two clasps, the Companionship of the Bath, and a year's service for Lucknow. He received the Victoria Cross "for most conspicuous gallantry and important services on the entry of the late Major-General Havelock's relieving force into Lucknow on Sept. 25th, 1857, in having during action (when the 78th Highlanders, then in possession of the Char Bagh, captured two nine pounders at the point of the bayonet), by great exertion and devoted exposure, attended to the large number of men wounded in the charge, whom he succeeded in getting removed on cots and on the backs of their comrades until he had collected the dooly bearers who had fled. Subsequently on the same day in endeavouring to reach the Residency with the wounded men Surgeon Jee became besieged by an overwhelming force in the Mote-Mehal, where he remained during the whole night and following morning, voluntarily and repeatedly exposing himself to a heavy fire in proceeding to dress the wounded men who fell while serving a 24-pounder in a most exposed situation. He eventually succeeded in taking many of the wounded through a cross fire of ordnance and musketry safely into the Residency by the river bank, although repeatedly warned not to make the perilous attempt."

HENRY JOHN BUTLER, L.R.C.P. LOND., M.R.C.S. ENG.

THE death took place on March 10th of Mr. Henry J. Butler of Bradford, Yorks, at the early age of 35 years. The cause of death was blood-poisoning following the prick of a safety-pin sustained whilst dressing a case of empyema. From the point of local infection the disease rapidly became general and after 10 days of great suffering death ended the illness. Mr. Butler was a native of Bradford and was educated at the St. James's Church School and the Bradford

Grammar School. After a successful student's career at the Leeds School of Medicine he filled the post of house physician at the General Infirmary, Leeds. 12 years ago he commenced practice in Bowling, Bradford, and quickly built up for himself a reputation as a conscientious and skilful member of his profession. He was very popular with his patients and was deeply respected by his fellow-practitioners. He was a member of the committee of the Bradford and District Medico-Ethical Society and he took great interest in its affairs. It was only on the evening before his fatal misadventure that he read a paper before the society upon the question of Hospital Abuse. A special meeting of the same society which was called for March 10th met and adjourned as a sign of respect to his memory after passing a vote of sympathy with Mrs. Butler in her sad loss. The funeral was attended by 30 or 40 of the medical men of the city as well as by several of the clergy and ministers of the district. The peculiarly sad circumstances surrounding Mr. Butler's death caused a deep impression upon the minds of all who knew his genial character and large numbers of the general public paid their last respects to his memory upon the day of his funeral. He has left a widow and three children.

HENRY JOHN KNIGHT, M.R.C.S. ENG., L.S.A., J.P.

VERY tragic circumstances attended the death of Mr. H. J. Knight of Rotherham who was found unconscious and in a dying state in his partner's consulting room on the afternoon of March 12th. At the inquest evidence was given to the effect that he had for some years been liable to periods of mental depression which had become worse since the death of the last of his brothers about a year and a half ago. One of these attacks had been continuing for the last two months and he had also complained of distressing cardialgia. The medical evidence was that a half-ounce bottle of prussic acid kept in the adjoining dispensary was found to have been emptied and that the use of the stomach-pump together with the administration of stimulant remedies failed to avert a fatal issue. A despairing note in the deceased's handwriting was also found in his pocket and the jury immediately returned a verdict of "Suicide during a state of temporary insanity." Mr. Knight received his professional education at the Sheffield Medical School and at St. Bartholomew's Hospital. He became qualified in 1858 as M.R.C.S. Eng and L.S.A. and had been in practice in Rotherham since 1864. Being very popular and highly respected he was chosen to fill several prominent public positions, such as churchwarden, manager of the national schools, president of the Rotherham Orchestral Society, &c.; he was also a Justice of the Peace for the borough. The utmost sympathy was everywhere expressed for the family and the funeral was very largely attended, among those present being the mayor and several members of the corporation, together with representatives of the churchwardens, of the Sheffield Medico-Chirurgical Society, and of the Rotherham School Board.

WILLIAM JOHN ALLKIN, M.R.C.S. & L.M. ENG., L.R.C.P. & L.M. EDIN.

THE death of Mr. Allkin of Denton on March 9th at the age of 60 years has called forth universal sympathy and regret in the district. For many years he had a large general practice extending over a wide area. He was much beloved for his genuine kindness and the poor of the district will miss his unobtrusive but ready charity. For more than 30 years he was medical officer of health of Denton and Haughton, and of Audenshaw for more than 20 years. For 22 years he was medical officer of the parishes of Denton and Audenshaw and factory surgeon for 17 years. His father was the first vicar of St. George's, Hyde. He was a Churchman and in politics a Conservative, but he avoided "the wrangles of the public platform," as publicity had no charms for him. His funeral was very largely attended by friends and the representatives of public bodies, while in the procession were mournful crowds of his fellow townspeople.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. George H. Rohé, Professor of Therapeutics and Materia Medica in the College of Physicians and Surgeons, Baltimore.—Dr. M. J. Saraiva, Professor of

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—e re- March the following candidates passed in the subranch indicated:—

Surgery.—C. J. Coleman, Cambridge and Birmingham; A. G. C. Davies (Section I.), Guy's Hospital; E. L. Gowlland (Sections I. and II.), St. Mary's Hospital; H. W. Hues, Birmingham; and W. A. H. B. Smith, King's College Hospital.

Medicine.—H. S. A. Davies (Section I.), Michigan; H. H. J. Edwards (Section I.), St. Thomas's Hospital; F. Golding Bird, Guy's Hospital; V. S. Partridge (Section I.) and R. C. Robertson, Charing-cross Hospital; and W. P. Williamson, McGill.

Forensic Medicine.—H. S. A. Davies, Michigan; H. H. J. Edwards, St. Thomas's Hospital; P. J. Fitzgerald, Dublin; V. S. Partridge and R. C. Robertson, Charing Cross Hospital; H. Whittaker, Cambridge; and W. P. Williamson, McGill.

Midwifery.—W. P. Allen, Birmingham; J. T. Crowe, St. Mary's Hospital; H. H. J. Edwards, St. Thomas's Hospital; W. M. Hocken, Liverpool; H. L. Laidman, Manchester; C. C. Morgan, St. Bartholomew's Hospital; F. C. Torbitt, Manchester; W. P. Williamson, McGill; and T. Young, St. Bartholomew's Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: Messrs. W. A. H. B. Smith and H. W. Hues.

FOREIGN UNIVERSITY INTELLIGENCE.—*Strasburg:* Dr. H. Eggeling has been recognised as *privat-docent* of Anatomy.—*Utrecht:* Dr. Heinrich Snellen is about to succeed his father, to whom he has hitherto been assistant, as Professor of Ophthalmology.—*Vienna:* Dr. Winternitz has been appointed Extraordinary Professor of Internal Medicine.

THE LATE MR. R. GRIFFITH.—Mr. Richard Griffith, L.R.C.P., L.R.C.S. Edin., of Glyn Neath, Glamorganshire, died on March 17th, at the age of 38 years. On Feb. 14th, as reported in THE LANCET, Mr. Griffith was thrown from his horse and sustained a fracture of the base of his skull. The deceased who was surgeon to several collieries in the district leaves a widow and two children.

PRESENTATIONS TO MEDICAL MEN.—On March 4th, at the Miners' Hall, Haswell, on the distribution of certificates to the successful students of the ambulance class held amongst the Tuthill quarrymen and others, Mr. S. A. Fothergill, L.R.C.P. Edin., M.R.C.S. Eng., of Haswell, the teacher of the class, was the recipient from the members of an easy-chair as an acknowledgment for his instructions.—On March 7th Mr. John T. Dickie, L.R.C.P., L.R.C.S. Edin., who has been in practice at Loanhead for the past 16 years, was entertained to a banquet in the Balmoral Hotel, Edinburgh, on the occasion of his leaving the district. A company of about 60 ladies and gentlemen assembled. Provost Gunn (Loanhead) presided and on behalf of Mr. Dickie's friends in the Loanhead district presented him with an illuminated address, a writing-desk, and a chair, together with pieces of silver for Mrs. Dickie.—The members of the Chippenham branch of the St. John Ambulance Society have presented Mr. W. T. Briscoe, M.D., M.Ch. Dub., with a hunting flask in appreciation of his services as honorary lecturer to the class.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Food Standards.

IN anticipation of the Committee stage of the Sale of Food and Drugs Bill Sir CHARLES CAMERON has given notice that he will move to insert in the Bill the following new clause, viz.:—

"The Board of Trade shall appoint a Standing Committee of Reference on Food Standards to be composed as follows: each of the following bodies, that is to say, the Local Government Board, the Board of Agriculture, the Society of Public Analysts, the General

Medical Council, the Institute of Chemistry, and the Pharmaceutical Society shall name a representative and the Board of Trade shall, if it think fit, appoint such nominee to be a member of the Standard Committee of Reference on Food Standards. But if the Board of Trade object to any person so nominated it may require any of the bodies aforenamed to nominate three persons, of whom the Board of Trade shall select one as the representative of the body on the said Standing Committee, and the principal officer of the Government Laboratory at Somerset House shall, *ex-officio*, be a member of the said committee. And the said Standing Committee are empowered to make such order as they think proper from time to time respecting standards of the quality and purity of food, and the orders, if and when they have been confirmed by one of Her Majesty's Principal Secretaries of State, shall have the force of law.

The Conscientious Objector

The Bill to repeal the Conscientious Objector Section in the Vaccination Act of last year came on for second reading on Wednesday, March 22nd, at a time when only non-contentious business could be taken, and as it was opposed the order had to be postponed. There is little chance of the Bill ever being discussed in the course of the present session.

HOUSE OF COMMONS.

Thursday, March 16th.

Medical Officers in the Navy

Captain Norton asked the First Lord of the Admiralty whether it had been brought to his notice that certain medical officers who entered the Royal Navy in 1878 and went through the 128 days' course of naval and military hygiene at Netley (at that time compulsory) on half pay had not been allowed to count that time for promotion, while others who joined the service some months later and were given direct commissions afloat, in consequence of what was then known as the Russian war scare, the hygiene course in their case being dispensed with for the time, had been promoted over the heads of the former through the latter having more full pay time, and whether, in order to remedy this, he would consider the advisability of altering the rules of the service so that the period of training at Netley Hospital might reckon as naval service for all purposes and so that the prospects of these senior officers for promotion from the rank of fleet surgeon to that of deputy inspector-general might not be prejudiced.—Mr. Macartney replied to the question saying: Certain medical officers were entered for immediate service in 1878 and did not go through the usual course at Netley. One of these officers after serving afloat applied to be allowed to go through the course and his time was allowed to count as a special case, as his application was a voluntary act and made under the impression that the time would count. It is not considered desirable to alter the rules, but directions have been given that when the time approaches for the promotion of officers entered in 1878 to the rank of deputy inspector-general their positions on the list shall be specially considered.

Cerebral Fever in the Soudan.

Mr Pirie asked the Under Secretary of State for Foreign Affairs whether the Government had any information as to the state of health of the native troops quartered at the present moment in the Soudan; whether it was the case that they were suffering to a great extent from cerebral fever from which, even if the attack did not end fatally, the patient never permanently recovered; what had been the mortality amongst those troops since our taking possession of the Soudan, and what was the percentage of deaths among those attacked by the cerebral fever.—Mr Brodrick replied: We have received no detailed report as to the state of health of the native troops at present in the Soudan, but such reports would naturally be addressed to the Egyptian and not to Her Majesty's Government. It is known that the troops operating on the Blue Nile have suffered severely from the climate there and the Egyptian army generally have been subjected to considerable strain during the last 12 months. Statistics as to mortality and sickness will be called for.

Friday, March 17th.

The Petroleum Question

Mr. Jesse Collings said, in answer to a question, that the Bill of the Home Office based on the recommendation of the Select Committee on Petroleum and Accidents arising from the Use of Petroleum Lamps will be introduced as soon as possible after Easter.

Medical Service in the Army.

When in Committee of Supply on the Army Estimates the House discussed at great length the case of a private of the 17th Lancers who died in Ballincollig from a clot of blood on the heart while undergoing punishment for breach of discipline. In the course of the debate it transpired that the medical man called in by the military authorities was not registered and this fact was severely commented upon by several members.—Dr Clark insisted that a serious mistake had been made, while Captain Norton declared that during the last 10 or 12 years they had never had in the army anything but the sweepings of the medical schools.—Mr. Carson, the representative of Dublin University, advocated a return to the system of associating the medical officer with the regiment.—Sir Henry Campbell-Bannerman who was Secretary of State for War in the last Administration addressed himself especially to this point. He reminded the House that there was a great deal to be said on the other side of the question. The evils of the old system, he said, were glaring and notorious. When the change took place, 26 years ago, he was a very subordinate official in the War Office and he knew that all the best opinion and experience in the medical service were in favour of the adoption of the general hospital organisation as superseding the regimental organisation. Everyone would see the advantage, and he need not dwell upon it, of having a medical officer in the regiment living among the men and taking a fatherly or brotherly interest in the men, but on the other hand, that medical officer gained little experience in professional life, having little experience beyond one or two classes of diseases and he would lose some of that tone and fibre which should be the possession of an experienced medical authority. That was one of the arguments which might be used, but it was not a question the House could now enter upon, and he only wished to warn those who were inclined to jump to the conclusion that a return to an antiquated discarded system would prevent accidents like these that the result would be more likely to be in the opposite direction. The dearth of medical officers in the army had been referred to and it was known what that had arisen from to a large extent—of which, he hoped the cause would hereafter be removed—the jealousy or distrust on the part of certain medical schools of the army as a career for a medical officer had been mitigated. It would readily be seen that there were very many cases in which a civilian medical officer must be employed and that it would be a waste of money, of power, and presumably of skill, to employ an army medical officer in every case when there was choice of civilian medical men at call in the immediate neighbourhood.

Monday, March 20th.

Venereal Disease in India

Major Rasch asked the Secretary of State for India whether his attention had been called to the fact that the returns for 1897 show an increase of secondary syphilis of 8·5 in admission rate per 1000, of mortality of 0·17, of constantly sick of 1·18, as compared with the previous year, and that the number invalided home was 662 in 1897 as against 479 in 1896, being an increase of 183, or 38 per cent., of venereal disease; whether the information in the hands of the War Office shows that this increased virulence is due to the fact that patients do not undergo early treatment but are removed from cantonments to spread disease elsewhere, and if it was the practice to treat men suffering from constitutional syphilis in barracks instead of in hospital, which causes an apparent reduction in the number of admissions and renders the statistics misleading.—Lord George Hamilton: The figures relating to venereal disease are correctly given by my honourable and gallant friend, but as regards admissions they are applicable to troops in cantonments only. The information available does not admit of any definite conclusion being drawn as to the cause of the increased virulence of secondary syphilis in 1897 as compared with 1896. Treatment of soldiers in barracks in certain stages of the disease has doubtless caused some reduction in the admission rate, but as it has been practised for some years it does not, I think, affect the comparison of one year with another.

Borax as a Food Preservative.

Mr. Kilbride asked the President of the Board of Agriculture whether he was aware that foreign bacon imported into this country had been found to contain 0·33 per cent. of boric acid and that the French authorities had refused to admit the importation of bacon thus preserved on the ground that it was injurious to health; whether he was aware that the law in Brazil prohibits the use of borax as a food preservative; and whether, in view of the action taken by other Governments, inquiry would be made into the use of borax in the interests of the public health.—Mr Chaplin replied to the question, saying: I was not aware of the facts alleged in the first and second paragraphs of the question and I have not yet ascertained how far they are accurate. The Local Government Board has no direct information on the matter. I am considering the question of such an inquiry as that suggested by the honourable member and if it should appear to be necessary or desirable in the interests of the public health it will be my duty to direct it to be held.

Tuesday, March 21st.

The Vaccination Question

Mr Logan asked the President of the Local Government Board if he proposed during the present session to so amend Section 2 of the Vaccination Act, 1898, as to prevent cases of an undue refusal by the magistrates to grant the certificates which were authorised by the Act.—Mr Chaplin said that it had already been announced on behalf of the Government that they did not propose to introduce any legislation on this subject during the present session.

The London Water Question

At this sitting of the House several private Bills dealing with the water-supply of London were discussed. Mr. James Stuart took exception to the Bill of the East London Company on the ground that in his opinion the River Lee is not a satisfactory source of supply. He moved the rejection of the measure but at the end of the debate he withdrew his motion and the Bill was read a second time. The chief debate, however, was upon the second reading of the Bill of the London County Council for bringing a supply of water to the metropolis from Wales. Mr James Stuart argued that for its future needs London could not rely upon the Thames and the Lee but must seek elsewhere for a satisfactory supply, and he submitted that the case was so urgent that Parliament should not wait for the report of the Royal Commission.—Mr Whitmore moved as an amendment "that it is inexpedient that the Bill be read a second time before the Royal Commission on the London Water Supply has presented its report," and this amendment was supported by the Government, Mr Chaplin saying that the Bill prejudged all the important questions referred to the Royal Commission. The amendment was carried by 206 to 130 votes.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

Anningson, B., M.D. Cantab., M.R.C.S., has been re-appointed Medical Officer by the Royston Urban District Council.

Arkwright, J. A., M.D. Camb., B.C., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Halesowen Sanitary District of the Stourbridge Union.

Bennett, P., M.B., B.Ch. Irel., has been appointed Medical Officer for the Attercliffe Sanitary District by the Sheffield Board of Guardians.

Burt, W. C., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Workhouse of the Torrington Union.
